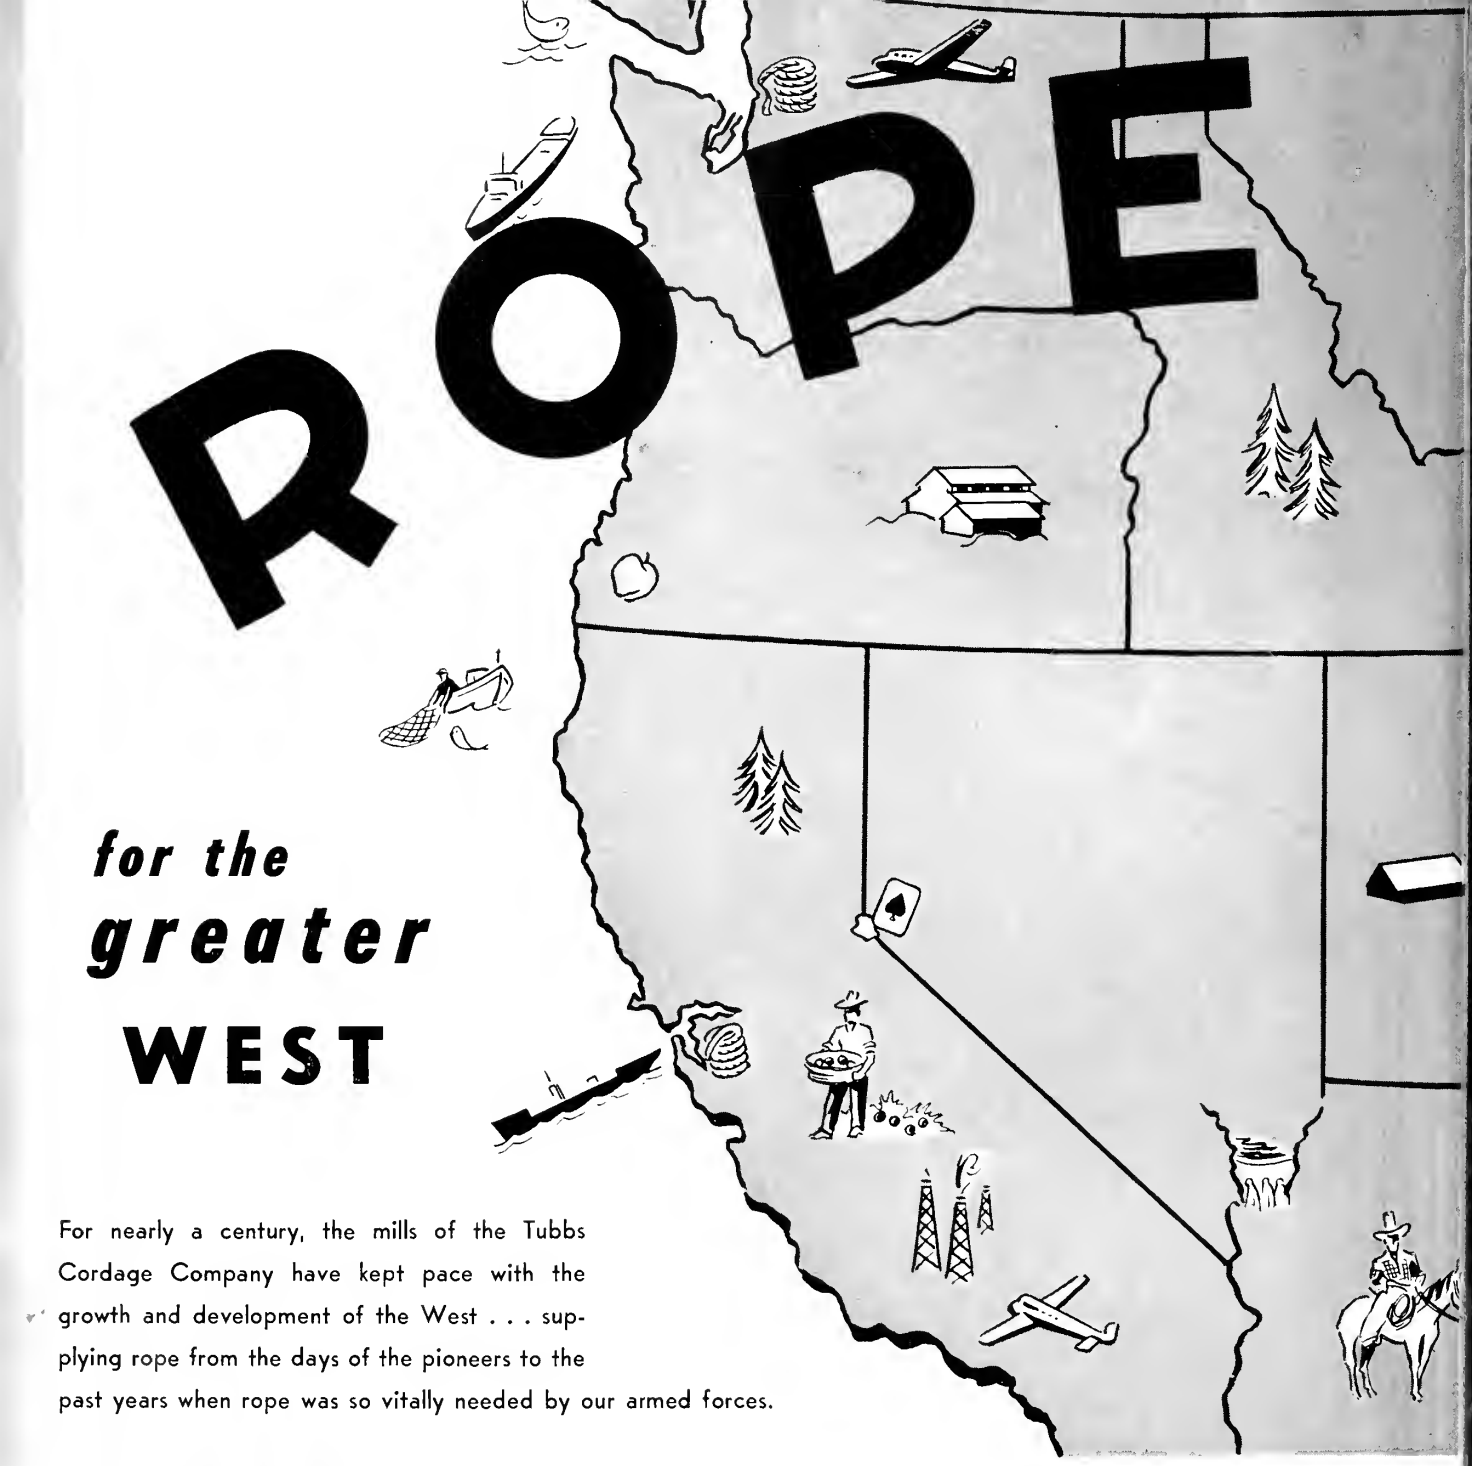
Pacific MARINE REVIEW

JANUARY 1946



for the
greater
WEST

For nearly a century, the mills of the Tubbs Cordage Company have kept pace with the growth and development of the West . . . supplying rope from the days of the pioneers to the past years when rope was so vitally needed by our armed forces.

TUBBS
EXTRA SUPERIOR MANILA
CORDAGE COMPANY

Now—in the days of the greater West ahead—our mills will once more produce the quality products that have made the name Tubbs stand for the maximum in rope dependability and value.

When the *finest* manila fiber is once more available you will again see this famous rope trademark.

BEFORE the War, our own organization in the Philippines selected the pick of the crop of manila fibre. They bought, graded, and packed the fibre which was made into the famous COLUMBIAN TAPE-MARKED PURE MANILA ROPE. Naturally, the war destroyed that organization and its facilities as a working unit.

Today, we are busily rebuilding that organization and its facilities under the most extreme difficulties and Pure Manila fibre under the Columbian label will be among the early ship cargos of fibre from the Islands. We cannot now tell you just when this will occur nor how soon Columbian Tape-Marked Pure Manila Rope will again be available. We do want to assure our customers that we are bending every effort to hasten the day when it will be plentiful enough to supply the great need for a high-quality, completely dependable rope. We believe that that day is not far off!

The Shipping Outlook

Pacific MARINE REVIEW

At the beginning of our 42nd year of continuous publication on the Pacific Coast, with grateful feelings we thank all the many friends for their seasonal greetings and wish for all readers and for the Pacific American Merchant Marine a very happy and prosperous year in 1946.

Much water has run under the American Merchant Marine bridge since Pacific Marine Review first made its public appearance at Seattle in April, 1904. Depressions, inflations, booms, wars, strikes, and controversies have continually rocked the boat; but the hull, well designed for stability, has weathered all conditions of sea voyaging and is still carrying good cargoes.

As we come into 1946, with another world war happily behind us and considerable uncertainties ahead, we have the largest fleet of seagoing merchant vessels ever assembled under one flag.

From the cold logical viewpoint only a portion of this tremendous fleet can be profitably used in commercial peacetime normal trade. However, trade does not always follow cold logical reasoning, and it is often possible to create and to divert trade into channels that on first blush appear to be very illogical.

Our sea-borne trade naturally divides itself into three classifications—Coastwise—Intercoastal—and Overseas or Foreign.

Coastwise seagoing trade includes Hawaii and Alaska on the Pacific, and Puerto Rico on the Atlantic, and so becomes geographically overseas. It is strictly confined to American Flag vessels and so is competing only with truck, airplane, and rail for passengers and cargo. Intercoastal trade also is confined to American Flag ships. Yet so great is the cost of American Flag operation that the operating companies do not wish to take back from the War Shipping Administration the vessels chartered for the war effort unless they can secure better freight rates. In some cases, notably Alaska, the present rates are claimed by the businessmen to be ruinously high. In all cases of ship operators the present demands of the seafaring unions are claimed to be ruinously high.

Overseas shipping is the point at which we may be able, with wise planning, to create a great increase in business. This is true in the Atlantic Coast-European, the Atlantic Coast-Central American, the Atlantic Coast-South American, the Atlantic Coast-African, the Pacific Coast-Asia, the Pacific Coast-South American, the Pacific Coast-Central American, and the Pacific Coast-Oceania ranges. Everywhere on the earth the war has created a large pent-up demand for the things of modern civilization. America is in a better position to supply that demand than is any other nation.

The loans we are making to many countries will produce a large volume of manufactured products for transport overseas, and most assuredly the overseas vessels of the banker should carry a very considerable portion of the product of these loans. This business if conducted properly should result in a large volume of permanent foreign trade that would keep many ships busy.

There are some obstacles—the demands of labor—the increasing costs of cargo handling—the increasing pressure of air competition. Fundamentally, however, surface water transport is still the most economical method of carrying goods over long distances and will probably be so always.

What is needed to maintain a large merchant marine is large volume of cargo and passenger traffic. This is possible in coastwise and intercoastal traffic only when American merchants realize again the fundamental economics of water transport; and possible in overseas traffic when the American manufacturer recognizes the great value of foreign trade and the fundamental economics of carrying that trade in his own flag vessels.

Both these possibilities are to a large extent dependent on common sense, good judgment and constructive cooperation controlling the councils of American Business, American Industry, American Ship Operation, and American Union Labor. The common denominator of these four factors in the word "American." Let's get together for an American Merchant Marine as a permanent business-getting, foreign trade building, American institution.

Let's keep our merchant marine LOADED. *The future of the shipyards, the manufacturers of equipment, shipyard and seagoing labor, and the cities that serve the ships,* ARE DEPENDENT ON LOADED SHIPS.

Analysis of Ship Repairs and Conversions

ON THE PACIFIC COAST

CONFERENCES during the past month with important shipbuilders, steamship officials, and officers of the War Shipping Administration, Army and Navy, indicate a volume of ship repair and ship conversion business beyond the ability of Pacific Coast shipyards to handle for several years.

Troop movements from the Pacific theater of operations reached their peak in December and will be well on toward completion during the spring. On March 2 the United Nations Shipping Pool will terminate, and on that date, or earlier, most of the commercial ships will be returned to private owners.

Every ship must, as provided by law, be restored to the condition in which it was received from private owners by the Maritime Commission. An alternative to this is for the owners to accept a lump sum cash settlement and restore the ships themselves. Thus if the conversion and repair jobs are to be handled by the Commission, it is likely that all shipyards capable of handling the work will be flooded with business, because all of the owners are clamoring for ships. Some of these conversion jobs will extend over a long period. For instance, the big Matson ships will require almost complete reconstruction at a cost that is estimated by Matson at $3,500,000 each, and will require from 6 to 15 months.

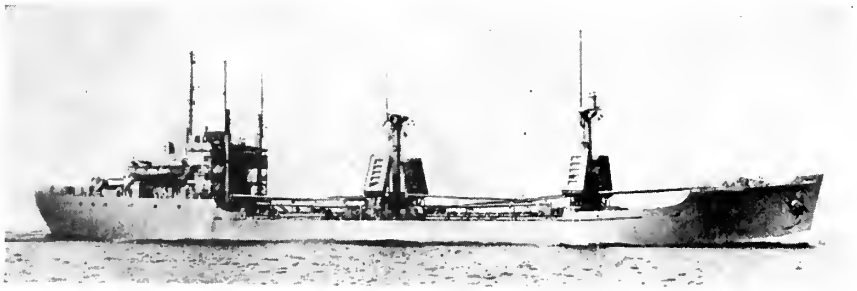
In the event that certain owners accept the cash settlement, a thorough inspection and in most cases drydocking will be necessary, with the probable changing of the arrangement plans on many vessels.

It is pointed out that in addition to the ships that are controlled by Pacific operators, such as American Mail, American President, American Hawaiian, Matson, McCormick and Alaska Steamship, there are as many as 25 sailings per month with United Nations Relief supplies for the Philippines, China, Russia, Korea and probably Japan and others, and these ships will be serviced on the Pacific. The relief program will extend through the year, under present appropriations, and may run into many years.

Further, there are many lines whose Pacific Coast general agents say their servicing will be done wherever yards are available.

On March 2 there will also be restored the rule requiring annual drydocking, and it is obvious that with the enormously increased trade to Pacific areas with a consequent increase of the number of ships operating on the Pacific, there will be the passing of German and Japanese prewar operations to American lines which will be controlled by American law.

It is understood that one important line with Eastern headquarters is transferring its entire engineering organization to the West Coast and will handle its repairs and service work in the West. And another line with head office in New York is transferring its operational management to San Francisco.



The C type and Victory type ships will nearly all require elaborate conversion. Above is a C-1-M-AVI. France is taking 5 C-1s. Below is a C-2. The C-2 type is now being converted at Consolidated for the International Freighting Corp. The U. S. Lines, Lykes Bros., Luckenbach and others are working on this model.

Ship Replacement

Every ship operator on the Pacific lost many of its ships. For instance,

Luckenbach lost 9 ships by enemy action, had 1 beached at Normandy, converted the 2 largest ships to hospital ships and another one to an animal carrier. These must be replaced, and the company will make selections from among the various C and Victory types which they are now operating as agents. It is expected that all will require important conversion and repair.

The American President Lines lost all but 3 of its pre-war ships and in addition to heavy replacements will probably be assigned a round-the-world route with several large vessels.

Matson will be taking 16 C-3's and may be making major design changes in their Big 4. The Alaska Steamship Company is planning a large new fleet. This service normally carries more passengers than all other Pacific operations combined. And so it goes with all of them. Of course, with the Intercoastal and Alaskan services, the freight rate and the cost of operations problems must be solved.

The Transport Service

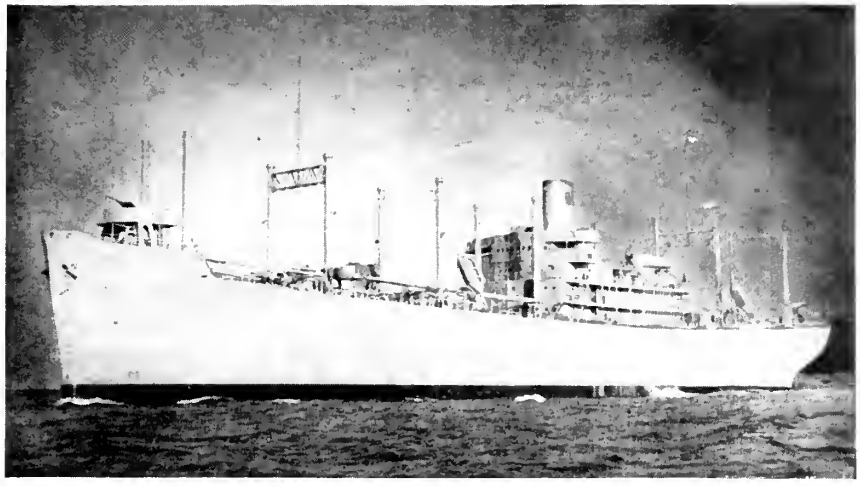
Before the war commercial lines handled the transport services for the Army and Navy. An officer of the Maritime Commission recently predicted that the Army and Navy will operate a considerable part of these services to the greatly increased number of remote bases which in the past have been either in the hands of other nations or been too unprofitable for American lines. The fact remains, however, that there will be more ships on the Pacific, with consequent voyage repairs and drydocking.

General

Few realize that during the war most ships received only emergency repairs. Nearly every ship that served the combat areas, as well as most others, received important structural damage. For instance, the dropping of a depth bomb usually caused the ship to heave violently with terrific strain on its structural parts. Ships under attack from either gunfire or bomb often received damage which can only be repaired after complete inspection, and this must be done in a shipyard. And all ships must be painted and their machinery overhauled or replaced.

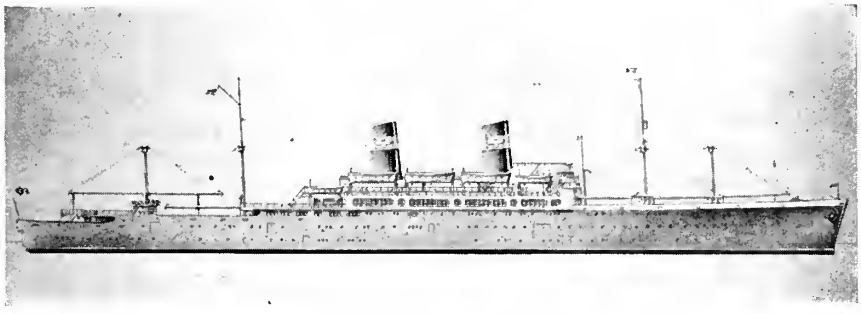
Ship Construction

Many important people in the in-



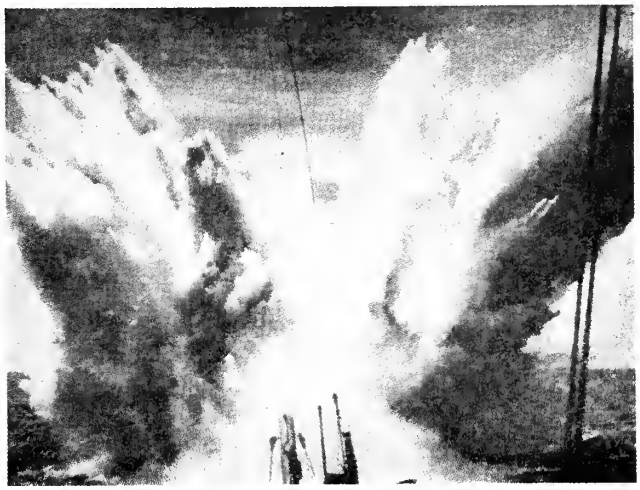
C-3, most popular of the C types. Will be converted by Matson, Grace, Lykes and many others.

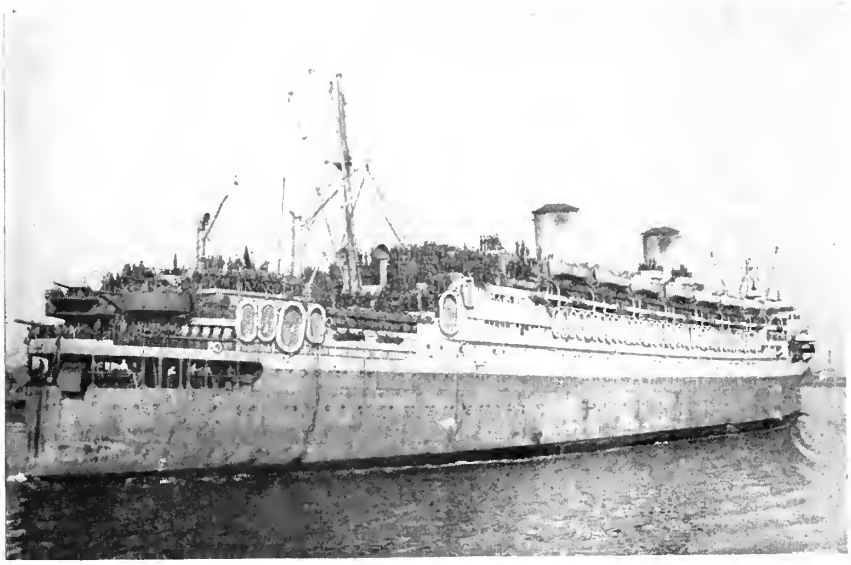
Artist's conception of what can be done with a C-4 for passenger service. Already in use or planned for American President Lines, American-Hawaiian and Luckenbach. Originally designed by American-Hawaiian for the intercoastal run. The Army may adopt the C-4 type.



Converted P-2 for American President Lines. **See feature story on page 16.**

This is what happened alongside a vessel whenever a depth bomb was dropped. The shock and strain ran through the entire ship.





Matson's Mariposo arriving from Europe with members of the 95th Division. A several-million-dollar conversion job will be required to restore her to the pre-war Mariposa in the lower picture on this page.

dustry confidently expect that either the Ship Sales Bill or an extension of the Merchant Marine Act will provide for a continuance of the program calling for the construction of 50 ships a year in order that the industry may be kept abreast of the art. In this event, certainly many of these ships will be built in Pacific Coast yards.

Small Boats and Commercial Craft

A revival of yachting in a big way is expected, and the smaller yards are busy with plans and work. Most of the yachts require complete overhaul and machinery replacement upon being restored to former owners. Commercial tugs, tankers, fishing boats and barges are being planned or built in many yards.

Foreign Vessels

With the elimination of innumerable shipyards in Europe and Japan, much of the work of European operators will be done in United States yards, and with many countries becoming merchant marine minded there will be many orders for American-built ships.

The Navy

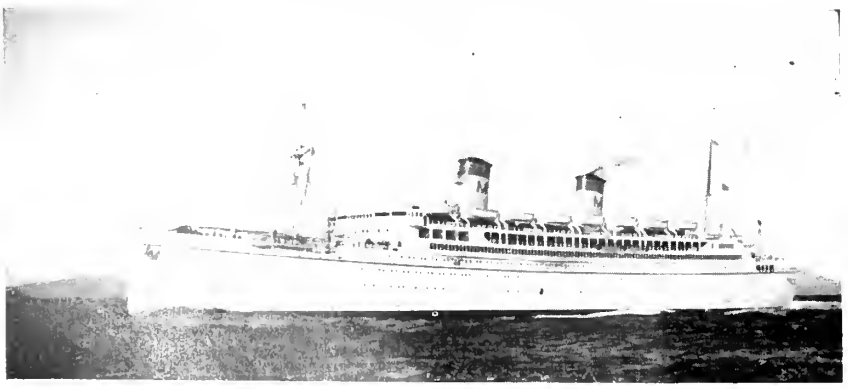
The so-called "Pre-Inactivation Overhaul" (the Navy will call the Reserve Fleet the Inactive Fleet) of most of the 1000 and more ships of the Navy will tax all of the Navy Yards on the Pacific Coast as well as the off-shore bases for upwards of two years, and there will be an overwhelming overflow to private yards in spite of the new and enlarged facilities at Hunters Point, Terminal Island and Pearl Harbor. Another article in this issue deals with overhaul program.

Radar

Sooner or later radar will no doubt be installed on all off-shore vessels. The Coast Guard has been holding hearings on the problem, and while the cost of the job worries some operators, the influence for safety will doubtless prevail. It will not be possible to complete all installations at once, but in any discussion of shipyard activity the radar installation program has an important place. On this subject also there is another article in this issue.

West Coast shipyards will not lack work for a long time to come.

The Mariposa, pre-war and post-war.



WSA Tanker Policy

Ocean tanker operations will be stabilized under a new War Shipping Administration policy of supplying tonnage to private owners and charterers whose fleets are unable to meet all demands.

As the result of the United Maritime Executive Board's decision to return to American owners 300 tankers of more than 3000 gross tons that were under requisition by the WSA, more than 200 tankers already have been restored to private operation. To insure orderly operation in the reconversion period and to avert discrimination and protect the industry against competition by the WSA tanker fleet, prospective voyage charterers of WSA-owned or controlled tanker tonnage must furnish the WSA Tanker Division by the fifteenth of each month with detailed statements or requirements for the following month's operation which cannot be supplied in the open market.

This will include certification that the open market has been thoroughly canvassed and found unable to supply suitable U. S. flag tonnage. Provision is made for submission of supplementary requests for tonnage made necessary by developments after the fifteenth of each month.

The WSA states that allocations will be for single voyages only, every effort being made to prevent employment of WSA tankers in commercial trades to the detriment of private tanker owners. Principal oil companies, brokers and other interests have been notified of the program, but services of brokers or agents employed by charterers will be at their own expense.

Reemployment Problems In Shipyards

By Joseph A. Moore, Jr.

THIS SUBJECT INVOLVES so many imponderables and uncertainties that it will be difficult indeed to give categorical answers to any of the pressing problems which are encompassed in the future employment and reemployment fields. I feel very much in the position of a department store manager who might be asked on December 26 to comment on immediate sales prospects! The shipbuilding and ship repair industries have just completed a period of growth and accomplishment unparalleled in the history of this nation or of any other nation. We entered World War II at a time when our naval and merchant fleets were far below the strength needed for ordinary peacetime operations. We did the job, and at this time it appears that generally speaking the shipbuilding industry will be turned loose to fend for itself, just as was done after World War I. We all sincerely hope and pray that never again may our nation need the industry as desperately in time of emergency as it did in 1941.

In considering prospects for utilization of man power in the industry we are immediately struck by the tremendous deflation that has already occurred. All statistics connected with World War II are startling and need not be stressed here. I would like to point out, however, that during the past five years naval and merchant ships were produced to a value of over 40 billion dollars, which represents about ten times our entire national budget as recently as 15 years ago. At the peak period of employment in 1943 over 4 million men, women and children were employed in our shipyards and in factories supplying goods and equipment for the shipyards. This represented approximately one out of 14 gainfully employed persons in the nation. It is obvious that at no time in the foreseeable future will any such production of ships and consequent tremendous employment of labor be possible, or even desirable, in the industry. Nevertheless, it is my belief that operations, hence employment, should, must and will be maintained at greater levels than prevailed during the decades of the twenties and the thirties. None of us should forget the days of only a few years ago when our industry did not rank among the first 50 in volume of products nor among the first 75 in number of employees.

Jobs in our industry will be furnished principally by conversion of wartime types of vessels to peacetime pursuits, by ordinary continuing voyage repairs, by adaptation of existing types to new uses and by construction of a certain number of vessels for our own and foreign governments and domestic and foreign private operators. The exact amount of such work will depend on whether sufficient activity can be maintained in U. S. shipyards during the peacetime years ahead to enable our country to keep adequately prepared for any emergency, to enable us to maintain our naval and merchant establishments on a par with those of other countries and to insure that this country will continue to carry a substantial percentage of our imports and exports in our own bottoms.

The question may be asked: "Why should shipyard activity and employment be maintained for the next ten years or so?" There are several reasons, but chief among them must be listed:

(1) The need for a constructive building program to maintain a minimum force of skilled mechanics for use in time of emergency.

(2) Need for maintenance of a modern and up-to-date merchant fleet which will be capable of competing in world markets and keep abreast of new developments in the shipbuilders' field.

(3) Maintenance of our position in the post-war world. Experience of other countries has proved that only through continual modernization and improvement of shipbuilding methods can the position of a maritime nation be sustained.

Several personnel problems peculiar to the present reconversion program are worthy of note at this point. First I should like to mention the problem of continued employment of female labor in the shipyards. Frankly, I believe that very few women will be employed in our post-war shipbuilding and ship repair programs. This detracts nothing from the magnificent performance that has been achieved by the women of America in our shipyards during the past few years. At one time upwards of 150,000 women, as well as many thousands employed in ancillary operations, were actively working in craft positions in our shipyards. With the lessening of activity and the return of veterans, this number is already very small and I believe that the end is in sight. To the women who came to our aid I say, "A job well done." It is my firm belief that but for the women of America the shipbuilding job could not have been accomplished.

Reemployment of veterans is a problem to which we will all be forced to devote an increasing amount of consideration in the months to come. In most cases the number of former employees in the Armed Forces has greatly exceeded the prospective total work forces for peacetime operation. I know that in the case of the company with which I am associated we have had some 24,000 of our employees leave us to go into the Armed Forces. Inasmuch as our peacetime employment will probably be somewhat under 1000, we feel that there is a very real problem here to be worked out. Furthermore, most of these men and women were unskilled at the time of their employment with us and it is very difficult to fit them into present activities. In many cases it will mean the release of old-time employees—men of high skill—in order to place returning veterans. This procedure will necessarily cause considerable readjustment within the crafts and in union-employer relationships. It is

(Continued on page 19)

(The author is president of Moore Dry Dock Co. He addressed the Merchant Marine Conference Panel on this subject at the recent Propeller Club Convention, and has herein amplified his remarks for Pacific Marine Review.)

THE ISLE OF THE MARE

A Modern Completely Equipped Navy Yard

(All photos Official U. S. Navy Photographs)

Rear Admiral Mahlon S. Tisdale, U.S.N.

FORMING A DELTA of the Napa River where that stream empties into San Pablo Bay (northerly arm of San Francisco Bay), there is an island of some 2247 acres. One of the legends of the Mexican days in California is concerned with the naming of this piece of land. General Mariano Guadalupe Vallejo, a Spaniard, had large grants of land in this vicinity and had large herds of horses and cattle. His favorite saddle animal was a white mare, and on a day when this mare was being transported across the bay with other animals the flat boat was wrecked and the white mare took a swim and scrambled ashore on this then desolate island. When she was found her Spanish owner immediately dubbed the spot as "Isla de Yuega," or the island of the mare, later contracted to Mare Island. This old story is the basis for the white horse on the emblem and the pennant of Mare Island Navy Yard.

In 1850, shortly after California was admitted as a state, Commodore John D. Sloat recommended the purchase of Mare Island as a site for a naval establishment, and it was acquired for $83,410. It was declared a Navy Yard in 1854 and Commander (later Admiral) David G. (Damn the Torpedoes) Farragut became the first commandant of the new yard. He brought out a corps of ship carpenters, most of them from around Boston and New York, and started to build wooden ships. At that time there were 12 vessels in the U. S. Pacific Naval Squadron, and Mare Island became their home port.

In 1849 prospectors traveling to the gold fields saw the advantages of the site on the mainland opposite Mare Island and founded a settlement known as Eden. A year later the name was changed to Eureka. In 1851 General Vallejo offered the State Legislature a considerable acreage and $370,000 in gold if the State capital was located on this site. The legislature accepted, changed the town name to Vallejo, and built a wooden "State House" of hewn planks from Hawaii, with a bowling alley and saloon in its basement. By 1852 Sacramento was luring the legislature, but they were prevented from moving there by the great spring floods of that year. Benicia in 1853 offered its new brick City Hall as a State Capitol and the government moved over there for a year or two until they were able to erect suitable quarters at Sacramento. Vallejo, however, became the home town for Mare Island workers, and has grown steadily with the growth of the Navy Yard.

First ship built at the yard was the wooden frigate Saginaw. Third and fourth generation descendants of the men who worked on this vessel are working in the yard today. After the Civil War practically all of the activity at Mare Island was repair and maintenance work on the Pacific Squadron. Practically the only steel work done from 1865 to 1898 was continuous repairs and rebuilding of the Civil War Monitor Monadnock, which was practically a new ship and ready for sea when the Spanish war started.

Rear Admiral Grover C. Klein, U.S.N.

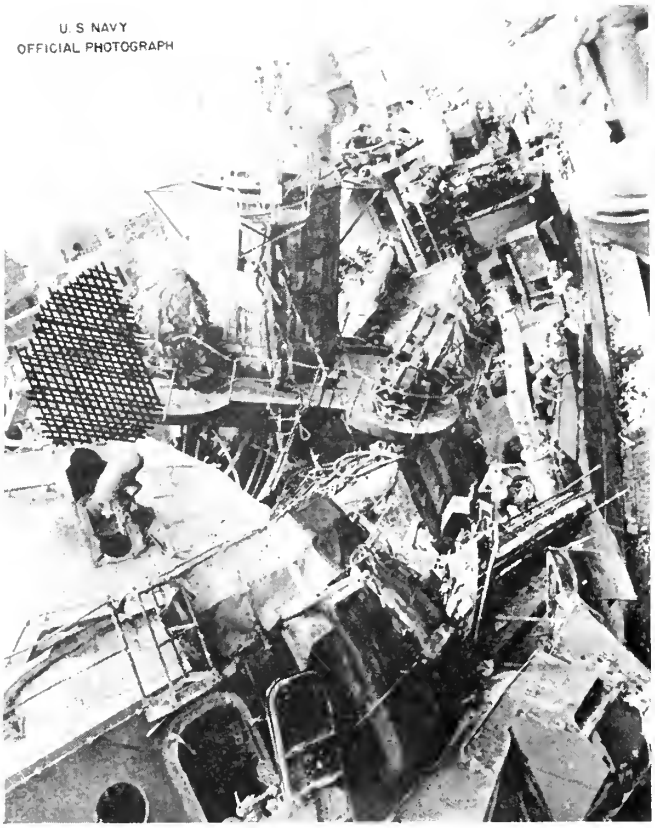
When the first of the then "Modern Navy," the U. S. Cruiser Charleston, was built at the Union Iron Works, San Francisco, and delivered at Mare Island in 1889, conditions were so primitive that she was warped into the dock by a yoke of oxen. Today practically the whole of Mare Island is covered by a huge naval establishment that during the peak of the war effort employed 42,000 civilians and thousands of Navy personnel in a tremendous program of ship construction, ship repair, and ship equipment designed to keep the Pacific battle fleets in order.

As of December 1 Mare Island Navy Yard becomes a part of the newly established U. S. Naval Base, San Francisco, and will hereafter be designated U. S. Navy Shipyard Mare Island. Rear Admiral Mahlon S. Tisdale, Commandant at Mare Island, will assume command of the Naval Base San Francisco, and Rear Admiral Grover C. Klein is expected to be Commandant at U. S. Shipyard Mare Island. Admiral Klein has been

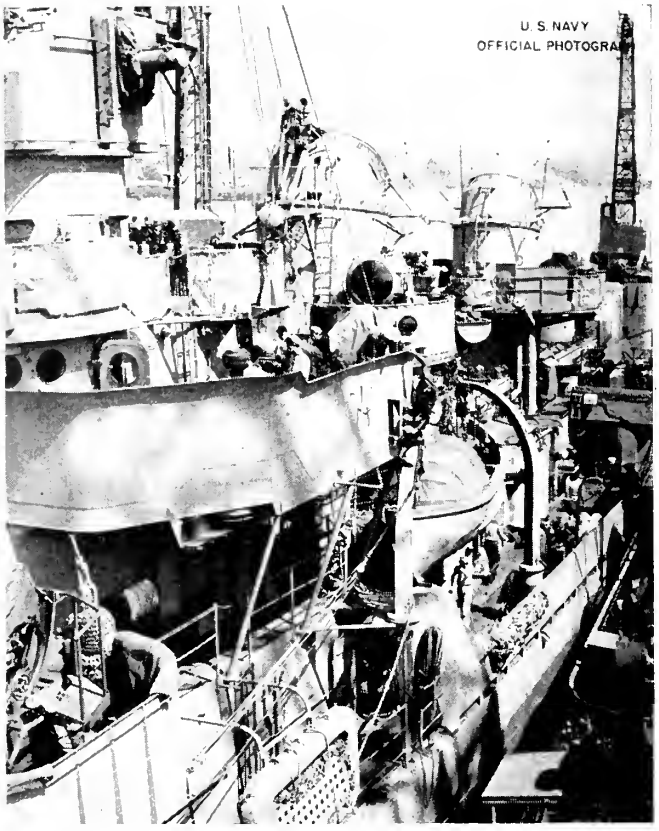
This recent aerial view of the gigantic Naval Shipyard, Mare Island, shows about three-fourths of the more than 2200 acres covered by the naval building and repair activities just across the straits from Vallejo, California. Of special interest is the cruiser in the drydock (in center part of the picture). It is ill-fated cruiser Indianapolis, sunk just prior to end of the war, and which was at Mare Island for repairs before leaving on her final trip.

On the right-hand side of the picture can be seen several of the 735 units of housing provided by the Navy for officers and enlisted personnel (and their families) at Mare Island while their ships are being repaired.

U. S. NAVY
OFFICIAL PHOTOGRAPH



U. S. NAVY
OFFICIAL PHOTOGRAPH

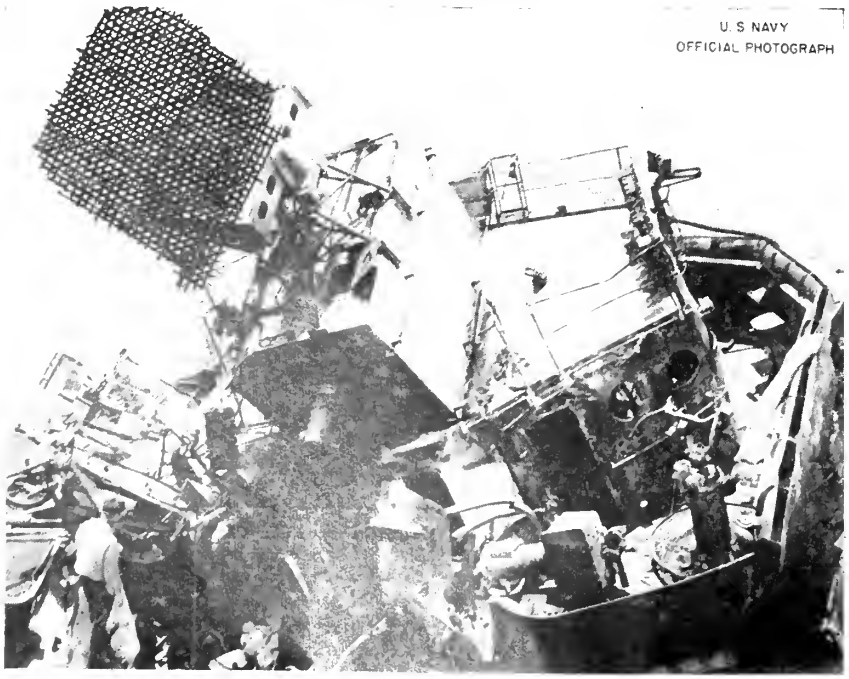


Left: The desperation of the Japanese, expressed through suicide attacks on American warships, is seen in this picture of the USS Hazelwood (DD531) shortly after a Japanese kamikaze pilot dived out of a low-hanging cloud to smash into the superstructure of the destroyer off Okinawa. About 22 per cent of the officers and men of the ship died or are missing from the explosion and fires started by this suicide plane. Over 96,000 man-hours, 60 per cent of it skilled labor, were required to put the area pictured here back in the fighting shape shown in the right-hand picture, only part of the 400,000 man-hours needed to repair the entire damage.

Right: This is how the Hazelwood looked before she was struck. The damage caused by this fanatical pilot is shown in the left-hand picture.

Here is an example of repair jobs that faced skilled Mare Island workmen during the hectic days when naval yards were trying to keep ahead of the deadly Jap kamikaze suicide pilots. Within a short time after the destroyer Hazelwood, shown here, arrived at Mare Island, she was again beginning to take shape as an efficient and deadly fighting craft.

U. S NAVY
OFFICIAL PHOTOGRAPH



industrial manager of the yard since February, 1944.

There are three principal branches of the Navy Yard, Industrial, Supply and Military. Captain Carleton R. Eagle is the Supply Officer and Captain A. G. Cook is Captain of the Yard with full control of military features.

Since December 7, 1941, four hundred vessels have been built at this yard, including destroyers, submarine landing craft, submarine tenders, destroyer escorts, and many types of smaller craft.

In addition to this huge new construction program and during the same period 713 vessels were repaired with a total man-day expenditure of 14,749,268. One hundred and fifty of these ships with a total man-day cost of 4,354,106, were completed during 1944. These repair jobs are mostly of the major type since minor repairs due to battle damage are usually effected at the fleet bases close to the combat zones.

Typical repair jobs were the U.

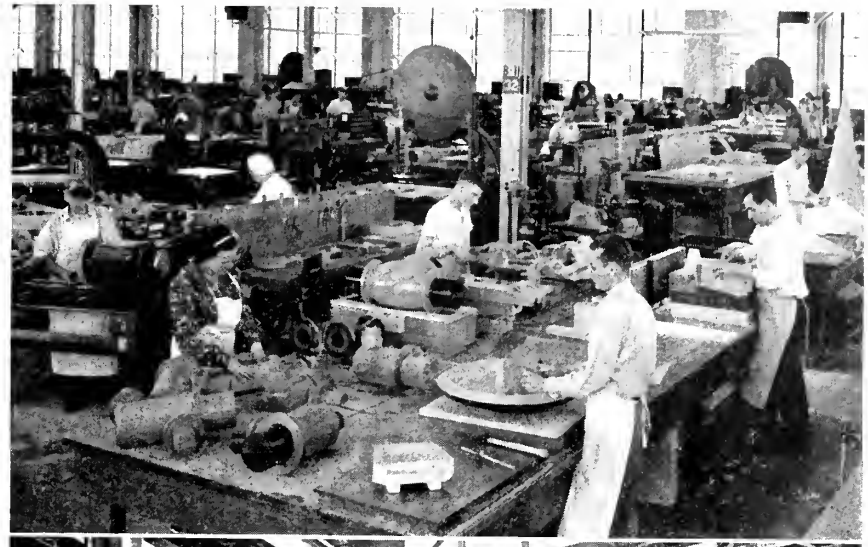
S. S. Denver, requiring 173,781 man-days, and the U. S. S. Alchiba (hit by three torepdoes and damaged by a big fire), requiring 81,399 man-days.

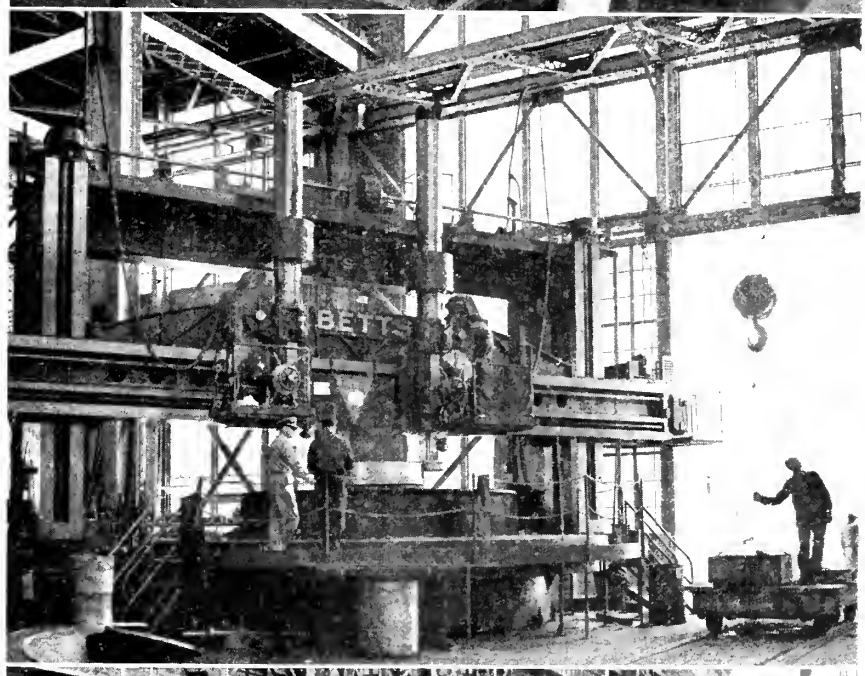
The southerly portion of Mare Island is hilly. Part of the south end is used as an ammunition depot with magazines honeycombing the hills and with facilities for loading ships' magazines and for unloading or loading ammunition ships. A little north of this is a section used for barracks and for 718 Homoja Huts. Here the men from ships undergoing repairs live with their families. There is also a Marine barracks area which is headquarters for the Marines who guard the island and run the Naval Disciplinary Barracks, which is a complete entity with Post Exchange, recreation center, ball field and other facilities.

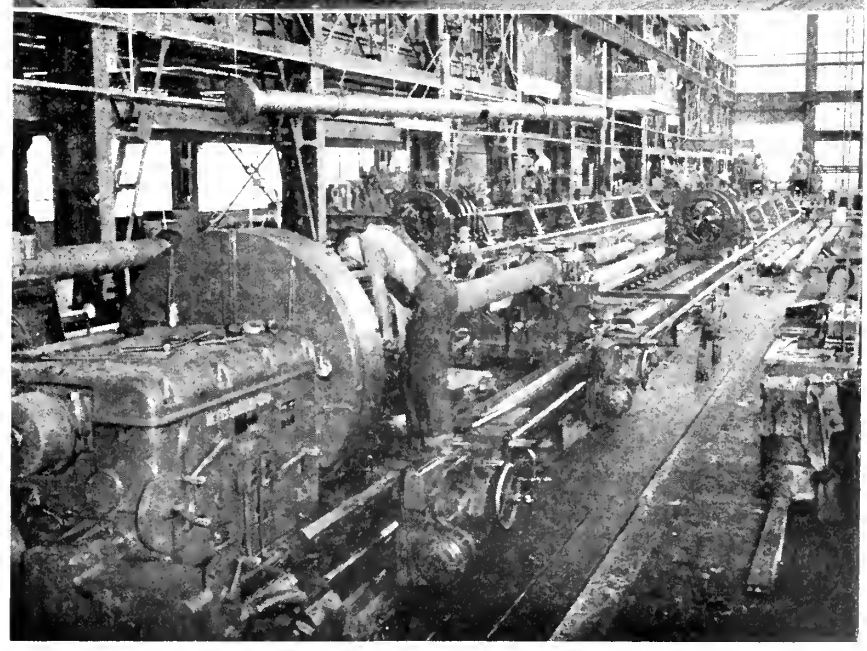
A Naval Hospital with a compound of 47 acres, rooms for 2000 bed patients, surgeries, laboratories, and facilities for production of individually fitted artificial limbs is part of this Navy Yard's equipment.

One of the most interesting shops on the island is the flag loft where at one time practically all the flags for the U. S. Navy were made. Here skilled women embroider emblems, cut out and fabricate pennants and flags, and listen to radio music broadcasts. At the peak there were 500 women employed in this shop, with a capacity for producing 80,000 flags a month. More than 3,500,000 pennants were produced by this shop during the war.

In the main industrial area of this yard are several of the largest shops of their type on the Pacific Coast. Most imposing of these is the machine shop, claimed to be the largest of its kind west of the Mississippi River. This huge structure is 904 feet long and 250 feet wide and therefore has a floor area of 226,000 sq. ft., or approximately 5 acres. At the peak 5000 machinists worked in this building. Of massive steel construction, it is served by numerous electric bridge cranes capable of handling the largest unit weights in naval machinery or ordnance. The floor is



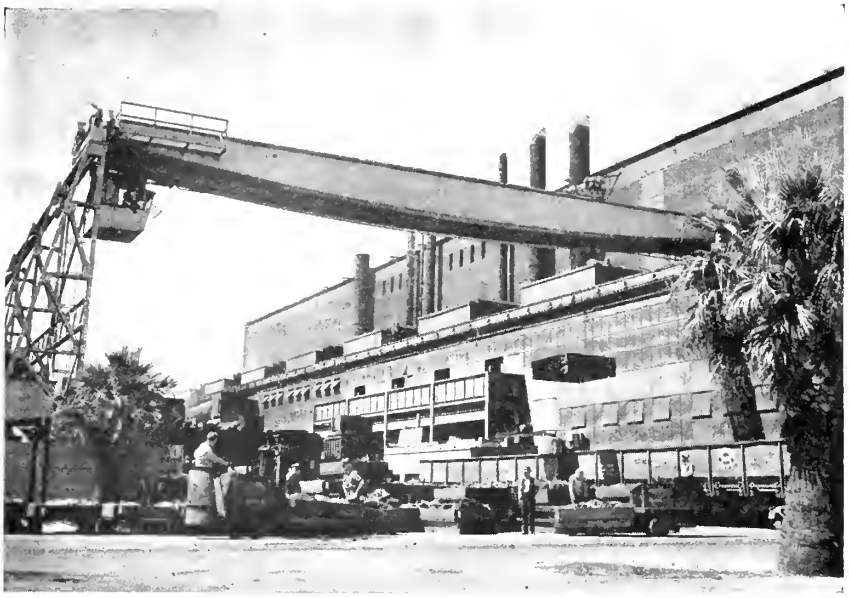




Top: A point of considerable interest at U. S. Naval Shipyard, Mare Island, is the mold loft, where wooden molds are prepared for later use in casting processes. This work requires highly skilled help.

Center: Nowhere in the West could you find a larger vertical boring mill than this huge machine that performs one of the major operations of making ship propellers in the Machine Shop.

Bottom: It requires highly skilled help to machine tool giant shafts at the yard. Many men and women make a lifetime career of this work at Mare Island.



An outside view of the foundry.

traversed by industrial trackage and by numerous covered trenches in which compressed air, steam, and waterpiping, and electric cables are carried to every part of the building. All large tools are driven by independently controlled individual electric motors. Many small tools are driven in groups from shafting actuated by an electric motor.

The equipment of this shop includes some of the largest engine lathes, open side planers, and vertical boring mills in the country. Large groups of turret lathes, milling machines and drill presses are arranged for multiple production of standard pieces of naval equipment or are ready for the special jobs that come in connection with replacing damaged hull and engine room machinery. Many of the machinists are second or third generation Mare Island employees.

This 2000-ton drop forge in the Shipfitters' Shop is the largest of its kind in the western part of the United States.

As in all the modern shop structures on the island, the machine shop fenestration is more than adequate. As will be noted in the pictures illustrating this article there is plenty of natural illumination and a minimum of shadow. The relatively large proportion of glass in the siding of these buildings is shown in the picture of the foundry.

In the pattern shop there are installed all the modern mechanisms for woodworking, and this establishment, together with its pattern storage warehouse, has been able to produce, when needed, all the patterns for iron, brass, or steel castings required by the tremendous building and repair program of the last four years. This shop is equipped with a special system that automatically disposes of all sawdust. Its intricate filing arrangements make old patterns available for use on demand, and the range available covers a very large proportion of the possible needs of standard naval vessels.

Modern in design and equipment, the foundry is another huge structural steel building. Its electric furnaces and cupolas have a capacity for large tonnages, and items are cast here daily ranging from a few pounds to many tons in weight. The molders in this plant include many highly skilled mechanics who have been trained in this yard as apprentices.

The largest single building in the yard is the structural shop. This building would cover four complete football fields. It is used by the welders and shipfitters. In the peak of employment 7000 employees worked in this shop. The equipment includes: multiple punches served by roller tables; huge rolls for shaping curves in ship plate; machine torches for trimming; automatic pantograph torches for multiple cutting; drill and reaming presses for plate work; huge shears for plate trimming; many jigs for welding; many welding machines and welding current outlets; and many flanging, pressing and forming machines.

Much prefabricating of large sections of ship hulls is carried on in this shop, which is adequately equipped with cranes and other facilities for moving these heavy assemblies.

Another important part of the plant is the shipsmith or blacksmith shop, where the forging of steel parts is done by large batteries of steam hammers and hydraulic presses, chief among which is the 2000-ton forging press. This is the heaviest press on the Pacific Coast.

Other shop units include: a boiler shop with complete equipment for overhaul, repair, or manufacture of any steam generator used in the Navy; an electric shop which repairs and installs complete electric systems on board ship, specializing on radar and fire control systems; a sheet metal shop which fabricates and installs lockers, metal furniture, ventilating ducts, and nonstructural metal hull work; a joiners' and boatbuilders' shop that manufactures and installs wooden items such as furniture, boats and cabinet work, and that handles all blocking, shoring, launching and drydocking; a paint shop that mixes and manufactures Navy standard paints; a paint department that does all the painting aboard ship and ashore; an outside machine shop that installs, removes, overhauls and repairs machinery aboard ship; and a pipe shop that shapes and installs all piping systems on shipboard, manufactures special tubular items from sheet copper, molds special rubber items, and maintains a rubber laboratory.

An industrial laboratory for testing materials and assemblies is maintained to insure maximum effectiveness and efficiency and to develop new processes and mechanisms.

A very interesting feature of this great naval shipyard is the apprentice system and school. Here ambitious

The last of many submarines to be launched at the yard prior to the end of the war was the USS Stickleback. On her bow is plaque stating: "This submarine sponsored and made possible by war bond purchases of the citizens of Yakima County, Wash."

young men are offered the highest grade of training in the various trades and at the same time can take accredited high school courses. This is arranged so that the young man can finish his high school course at the same time that this apprenticeship is over and in not much more elapsed time than he would take in the normal period devoted to the high school course alone.

In short, U. S. Navy Shipyard Mare Island is a very complete shipbuilding and ship repair yard wherein, if necessary, every item that goes into the completely equipped naval vessel can be manufactured. It is one of the oldest industrial establishments on the Pacific Coast and for many years has maintained a very high standard of craftsmanship and quality of output. It is one of the two U. S. Navy yards in the United States chosen for building, equipping, overhauling, and repairing submarines, and it will continue to be a busy shipyard for many years to come.

Sanitary Precautions On Vessel Reconversion

Leading American vessel operating companies are being offered United States Public Health Service facilities for the planning and effecting of ship sanitation in their reconversion of war-service vessels to peacetime commercial use.

Notification of the available services for ships of U. S. Registry has been sent to the larger operating companies by the Sanitary Engineering Division of the Public Health Service, Federal Security Agency. Upon request, Public Health Service personnel will guide the planning of the sanitary aspects of reconversion and furnish inspectional service during construction, alteration or extensive repair of vessels.

The Public Health Service is seriously concerned with adequate sanitation and ratproofing of vessels being converted or reconverted for commercial trade. The conversion of vessels for war use resulted in changes and additions which may have introduced potential hazards in the drinking and culinary water supply system, and in the facilities for food storage and handling. Harborage for rats may also have resulted.

In addition to its provision of healthful sanitary safeguards aboard ships, Public Health Service guidance in vessel reconversion would facilitate clearance of vessels in foreign trade through quarantine and would also aid in control of interstate spread of communicable diseases by coastwise vessels.

In its offer to the companies, Public Health Service points out that an adequately ratproofed vessel, with a good record as to absence of rat infestation and generally favorable sanitary conditions aboard, may clear quarantine without fumigation and thus effect a considerable saving in time and money.

Vessels which were ratproofed when built or prior to the war should be returned to a completely ratproof condition when reconverted, according to the Public Health Service. On other vessels, all rat harborages created by the conversion or reconversion should be ratproofed and ratproofing should be extended to other parts of the ship insofar as practicable.

Vessels on which the potable or drinking-culinary water system was constructed and certified as meeting the requirements of the Service should be brought into conformity with those requirements on reconversion. On other vessels all cross-connections between the potable or drinking-culinary system and any other system should be completely removed and any other major defect should be corrected.

Shipboard Corrosion Problems

By Kenneth Tator

SHIPBOARD CORROSION PROBLEMS fall into two categories: those which painting will prevent; and those for which paints offer no appreciable relief. For example, it would be a waste of money to use any protection other than a well-designed and properly applied paint system on hall or house plates to protect these from rusting caused by salt spray or sea water. Painting, however, has been not too successful in preventing corrosion of steel propeller shafts driving bronze wheels. For their protection a heavy, resilient synthetic rubber has given the best protection. It is of this latter class of corrosion protection that this article deals, that of linings or coverings.

Linings and coverings with but few exceptions are characterized by their thickness, normally from 3½ to ¼ of an inch. They are usually resilient, rubber-like materials, selected for corrosion and abrasion resistance. No one lining material will be a universal panacea for all corrosion problems, but among the lining materials commercially available there is generally at least one which will solve any specific problem. Among those materials available, and in common use for lining or covering, are rubber and the many types of synthetic rubbers, and plastics such as the Bakelites, vinyls, polyethlene, polystrene, vinylidene, chlorides and others. Unfortunately for many purposes these lining materials are seldom known by their true names, and their identity is obscured by non-informative trade-names. The writer recently visited the engineering division of a well-known organization which was then attempting the solution of a serious corrosion problem. Those men had invested a considerable amount of time and money in exhaustively testing eight lining samples, known only to them by trade-name, which had been recommended to them for the purpose. Of these eight test pieces, six were of identical material, differing only in trade-name, minor composition, and integrity of the manufacturer—an unnecessary duplication of investment, especially in view of the fact that this material proved inferior to other materials available. Such a situation can be avoided by asking the supplier the true nature of this material, or by enlisting the advice of men able to distinguish between the available trade-names.

Linings and coverings cannot economically and should not replace painting. Paint systems are adequate for the more common corrosion problems encountered on board ship. Furthermore they can be effectively applied by relatively unskilled workmen, with a minimum of specialized equipment. Their applied cost is low, rarely attaining 25c per square foot of surface painted. It must be borne in mind, however, that a paint film seldom exceeds twenty thousandths of an inch in thickness; that it is applied as a liquid and often remains a liquid for some time after it is applied, thus allowing it to flow back from and leave insufficient protection over sharp projections and edges. First signs of paint failure usually occur at sharp edges. In most instances failure from these causes is of little consequence as it is usually a simple matter to get the paint can and brush out and touch up these spots as failure is detected.

Linings and coverings are a different matter. Their application requires skilled workmen and specialized equipment. They are seldom applied in their entirety by brush or spray gun. They are never air-drying, but require some form of treatment to develop in them their maximum corrosion resistance and physical strength. For these reasons they are comparatively expensive. Linings, depending upon their nature and protection desired, will cost applied from 50c to $3.00 per square foot of surface lined or covered. For this reason if for no other, their consideration should be reserved for those uses where painting is inadequate and where the value of the parts which require protection is sufficient to justify these costs.

The virtues of linings lie in several properties, one of which is their thickness. This is especially important in abrasive exposure as, all other things being equal, the length of time they will afford protection will be in direct proportion to thickness. This greater thickness also presents a more substantial barrier against highly corrosive environment than a thin film. Furthermore, any defect in a thin film will almost certainly penetrate the film, but in a lining or covering this defect would be entirely surrounded by sound, resistant material.

View showing various stages in the lining of a hold.

(The author is president, Industrial Lining Engineers of Edgeworth, Pa.)

Sharp projections and edges are fully protected by sheer bulk of lining material.

Lining materials are usually resilient and rubber-like. This property gives still further protection against abrasion, as such abrasives will "bounce" off the lined surface instead of digging in and tearing up the surface. The success of the rubber-lined shaft bearings is evidence of this, to say nothing of the wearing qualities of automobile tires. Resilience is also of advantage in maintaining a protective barrier over "working" rivet heads on lap seams. The material at these points will stretch and "work" with the steel instead of cracking under the shearing action.

Linings and coverings are usually treated after application to impart to them their maximum resistance and strength. This "set," "cure" or vulcanization is variously accomplished by heat, pressure vapor or gas reaction. Special portable equipment is required. This operation after application insures maximum adhesion to the steel and a stress-free lining.

Lining and covering is in general accomplished by four different methods, depending upon the material employed or the result desired. They may be applied to specially prepared surfaces by pressure guns, by trowel, and by molding, and those so applied are characterized by being continuous and seamless. Sheet linings necessarily have seams but are usually smoother, of more uniform appearance and of uniform thickness.

Repairability of a lining is of paramount importance to shipowners. For protection as costly as lining or covering it is not economically desirable to replace a lining which has sustained damage to a small part of its total area. All linings cannot be repaired, but those which are classed as "thermoplastic" can be repaired with a minimum of time and expense, whereas with the "thermosetting" materials a repair is a major undertaking yielding a resulting lining which is often a compromise in quality. Hence in the summary at the end of this article the various lining materials will be classified according to their type.

Linings serve three types of function: they protect marine equipment from severe corrosion action of sea water, salt spray, or the cargo; they protect equipment from the abrasive action of silt, hard fuels, or solid bulk shipments; and they protect cargoes from undesirable contamination by iron or rust from contact with the bulkheads in the holds.

In the following the qualifications and uses of some of the principal lining and covering materials will be summarized:

Natural Rubber

Thermosetting. Best abrasion resistance. Excellent resistance to acid and alkaline conditions. Should not be used where lubrication oil or fuel oil will come in contact with it. Not suitable for oily shipments. Used to line battery compartments.

Synthetic Rubber—GR-S Type

Same general characteristics as natural rubber, but harder, hence with somewhat lessened abrasion resistance.

Synthetic Rubber—Buna N Type

Thermosetting. Good abrasion resistance. Excellent resistance to lubricating and fuel oils and to petroleum products. Excellent for vegetable oils and oily loadings.

Neoprene

Thermosetting. Excellent abrasion resistance. Excellent resistance to lubrication and fuel oils and to petroleum products except aviation gasoline, due to aromatics. Excellent for vegetable oils and oily ladings.

Thiokol

Thermosetting, although latex types readily repaired. Poor abrasion resistance. Has tendency to flow under pressure. Best resistance to petroleum products, including aviation gasoline, and used to line steel and concrete tankers and tank barges. Used to cover propeller shafts and streets. Not recommended for temperatures above 120 ° F.

Vinyls

Thermoplastic. Good abrasion resistance. Excellent resistance to alkaline and acid conditions, petroleum products, fats and oils.

Polyethylene

Thermoplastic. Fair abrasion resistance. One of best for acid and alkali resistance. Softened by contact with petroleum oils.

Bakelites

Thermosetting. Poor abrasion resistance. Excellent acid resistance. Poor alkali resistance. A glass-smooth thin lining with relatively good heat transfer properties, used to cover and line pumps, steel condenser tubes, pipes and fittings. Will withstand temperatures in excess of 350° F.

Polystyrene

Thermoplastic. Excellent acid and alkali resistance. Poor resistance to petroleum products.

Vinylidene Chloride (Saron)

Thermoplastic. Good abrasion resisitant to salt water and spray. Are not recommended for temperatures continuously above 200° F.

A lining installation.

Bethlehem's Repair Facilities At San Francisco

Said to Be Largest Private Plant of Kind in U. S.

MORE SHIPS can now be berthed for repairs or conversion at Bethlehem's San Francisco Yard than in any other privately operated repair yard in the country. "The recent addition of a 14,000-ton floating drydock and a 1300-foot-long pier puts the San Francisco Yard in first place in terms of capacity for reconditioning ships," W. M. Laughton, general manager of Bethlehem's West Coast Yards, stated. The two new facilities are Navy-owned.

In addition to the new 14,000-ton floating drydock, the yard operates a 22,000-ton, an 11,000-ton and a 6500-ton floating dock. Ships ranging in size from a tug to a luxury liner can be drydocked for repairs. The yard's eight piers with a total tie-up space of 14,000 feet will accommodate a fleet of twenty-five 2200-ton destroyers or Liberty ships at one time.

The San Francisco Yard's record during the emergency period in repairing or converting over 2500 vessels is outstanding. These ships ranged from the smallest minesweeper and fleet tug to the 36,287-ton ship S. S. Nieu Amsterdam, and 32,000-ton battleships were not an uncommon sight at the Bethlehem yard during war years. In 1942, the USS Pennsylvania, commissioned in 1916, underwent a complete modernization, and this was followed by the 25,000-ton aircraft carrier Essex, which was given a 30-day overhaul. This included new radar equipment, secondary batteries, revamped flag quarters, a changed island structure and stowages for droppable fuel tanks. Largest battlewagon in the yard was the California. Others included the Mississippi, Nevada and Maryland.

The yard also holds the distinction of having been the only submarine repair base in the country operated by a private company. Thirty-one of the undersea craft were completely overhauled here. The complete removal of all quipment and working parts was required on each job, leaving only the shell. The main engines were removed and brought into the machine shop on individual cradles and rolled from one end of the shop to another, during which time they were completely disassembled, cleaned and then reassembled with the addition of necessary new parts. Parts not immediately available on the Coast were made right at the base. All batteries and electrical equipment were removed and repaired in shops at the base or at the main yard.

Many foreign ships also put into Bethlehem's San Francisco Yard for repairs—Russian, Javanese, French—but the largest of them all was the Nieu Amsterdam, biggest Dutch vessel afloat, then a troop carrier. Bethlehem workmen gave her a major overhaul, made changes in her armament, in troop arrangements and troop carrying facilities. The Navy troop transport Montecello, once the Italian luxury liner Conte De Savoia, also was a visitor. These, however, were the torpedo, bomb and shell days of the early war years. The Kamikazes came later, and with them came more ships to Bethlehem. The yard's repair facilities were jammed in the spring of 1945, when 80 per cent of its 10,500 employees were engaged in repair work—10 hours a day, 7 days a week.

Typical of the ships that limped in for mending and sometimes virtual rebuilding were the USS Caldwell, a Bethlehem-built destroyer, struck from the starboard aft quarter in the radio room by a suicide plane carrying two bombs. One exploded in the No. 2 handling room and the other struck the superstructure. Only the 5/8" STS steel on the pilot house saved the personnel inside. The first shell, after exploding in the handling room, went on down through the crew's scullery and 18 inches of metal mess trays, which probably prevented it from going all the way through the bottom of the ship.

Ship repairs take equipment and machinery, and Bethlehem's two machine shops are the most complete and modern on the West Coast. The Navy owns some of the machine shop equipment, but all is operated by Bethlehem personnel. The two shops are equipped with overhead cranes with lifting capacity up to 60 tons, lathes up to 125-inch swing and 39 feet long, and others with a 48-inch swing and 64 feet long; vertical boring mills up to 22 feet in diameter; a 72-inch horizontal mill which is a combination draw cut shaper and milling machine; hydraulic presses which exert pressures up to 500 tons; assorted portable boring bars for boring large or small cylinders and shaft taper couplings and taper coupling bolt holes; and portable machines for turning crank pins in place.

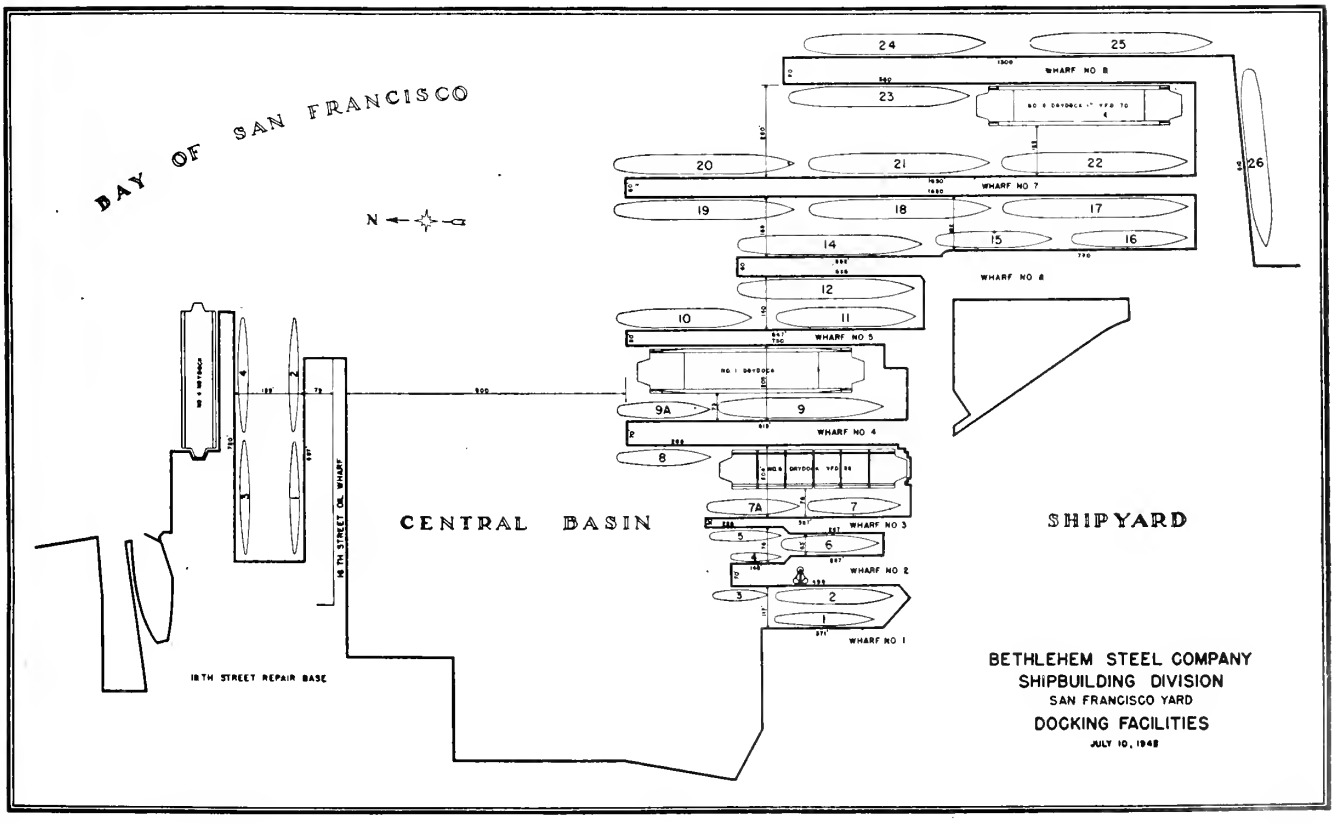
It was these machines and others—some developed by War Production Board Citation Winner Victor Lepkey, a San Francisco Yard machinist supervisor—that helped get ships off drydock, and others speeding back to the war zone in record time.

All repair work was not done in the machine shop, however; other departments drew an equally heavy load—the electrical department, the welding department, the copper shop, and the pipe shops. The blacksmith shop is equipped with a 1000-ton hydraulic press; two 30-ton cranes and steam hammers which exert pressures of from 800 to 7000 pounds. This shop can handle jobs from a 30-ton shaft down to the smallest door hook.

An indication of the magnitude of the yard's wartime repair and new construction program is found in the following monthly requirements: 56 million gallons of fresh water, enough to supply a city of 15,000 population; 860,000 kilowatt hours of electricity, which is comparable to an amount consumed by a city the size of Redding, California, with 10,300 population; 37 million cubic feet of natural gas, sufficient to supply the city of Eureka, California, with an estimated population of 20,000.

Wartime activities of Bethlehem Steel Company's San Francisco Yard were by no means confined to repairs. Fifty-one combatant ships were completed, and these included four high-speed anti-aircraft cruisers.

Bird's-eye view of Bethlehem Steel Company's San Francisco yard, the Risdon plant, naval yard, and the submarine base, all operated by Bethlehem. Upper right shows San Francisco Bay Bridge. The Bethlehem yard includes four flooting drydocks—22,000, 14,000, 11,000 and 6500-ton; tie-up space on piers, 14,000 feet; capacity for Libertys or destroyers, 29 at a time; number of vessels repaired or converted during war, over 2500.



Converted P-2 Passenger Liners

IN THE NOVEMBER, 1945, issue of Pacific Marine Review we published the general arrangement and profile drawings of the P-2 Army transports built by Bethlehem Steel Company Shipbuilding Division at its Alameda, California, shipyard. Herewith we are presenting the general arrangement, profile and midship section drawings of the same type of ship, two of which are now being built at the Bethlehem Alameda Yard as transpacific passenger liners for the Maritime Commission.

Propulsion is by the turbo-electric system with two separate turbine rooms and two separate motor rooms. Each turbine room contains two Combustion Engineering steam generators designed to operate at working pressure of 600 psi, and a temperature of 825° F. at the superheater outlet. This steam from each pair of boilers goes directly into a main propulsion General Electric turbine generating set that normally operates at 590 psi 815° F. throttle and exhausts to the condenser at a vacuum of 28¾" Hg with injection temperature for the cooling sea water at 70° F. Each main propulsion turbo generator set is designed and nozzled for continuous operation at 7650 K.W. running 3715 rpm with steam at 585 psi and 840° F. Each of these main generators is directly connected through suitable control and switchboard arrangements to one or both of the main propulsion motors. The current is three phase 60 cycle A.C. at 3500 volts. Each motor is rated 10,500 shp for maximum continuous duty and is directly connected to a propeller shaft. At the normal rating of 9000 shp the propeller turns 124 rpm. A complete description of this power plant and the auxiliary machinery of this type of vessel was published in Pacific Marine Review, October, 1944.

The hulls are largely welded but there are 350,000 rivets used in the hull joints. A curved stem, a modified cruiser stern and graceful sheer give the ship a fine profile appearance. Good propulsive efficiency is guaranteed by the finely molded underwater body and the long easy run aft. All scantlings, plating, subdivision of hull are designed to the highest class of the American Bureau of Shipping, and equipment is installed to conform to all the regulations of the various Federal agencies, bureaus, and regulations governing American shipping, such as:

Division of Marine Inspection, U. S. Coast Guard
International Load Line Convention
U. S. Public Health Service
International Convention for Safety of Life at Sea
Senate Report 184
U. S. Customs Admeasurement
Panama Canal Regulations
U. S. Maritime Commission

General characteristics are shown in the table herewith.

Promenade Deck

The promenade deck extends from the stern to frame 165. The after part of this deck from frame 75 to frame 165 is devoted to an enclosed promenade and the public rooms for cabin class passengers. A built-in swimming pool occupies the after portion of this enclosed deck area, and moving forward from the pool the plans show: a marine veranda; a cocktail lounge; the main stair hall with shops and service rooms; the smoking room; a library port and a writing room starboard; the forward stair hall with service rooms; and at the forward end of the house a main lounge or social hall.

Upper Deck

From frame 48 to frame 145 the upper deck port and starboard is occupied by 49 cabin class staterooms and two cabin class suites. Forward of frame 48 this deck is arranged for quarters for seamen, bo'suns, quartermasters, storekeepers, and carpenter. Each cabin class room is arranged with its own bathroom equipped with either bath or shower and toilet. All of these rooms are outside rooms and each of the two suites has a veranda, a sitting room, a bedroom, and a bathroom. All the staterooms are outside rooms. Between frames 145 and 166 are located a gymnasium, a massage room, and a children's playroom, and the tourist class lounge and smoking room, each of which has an enclosed promenade. In hatch No. 7 on this deck there is arranged a tourist class swimming pool.

"A" Deck

From the stern to frame 115 on "A" deck the entire space is devoted to engineers, petty officers, and steward's department. In this space at frame 87 is the hatch for refrigerated cargo spaces. This hatch will be served by a special crane that hoists the cargo out and runs it to and through the side port on either end of athwartship passage.

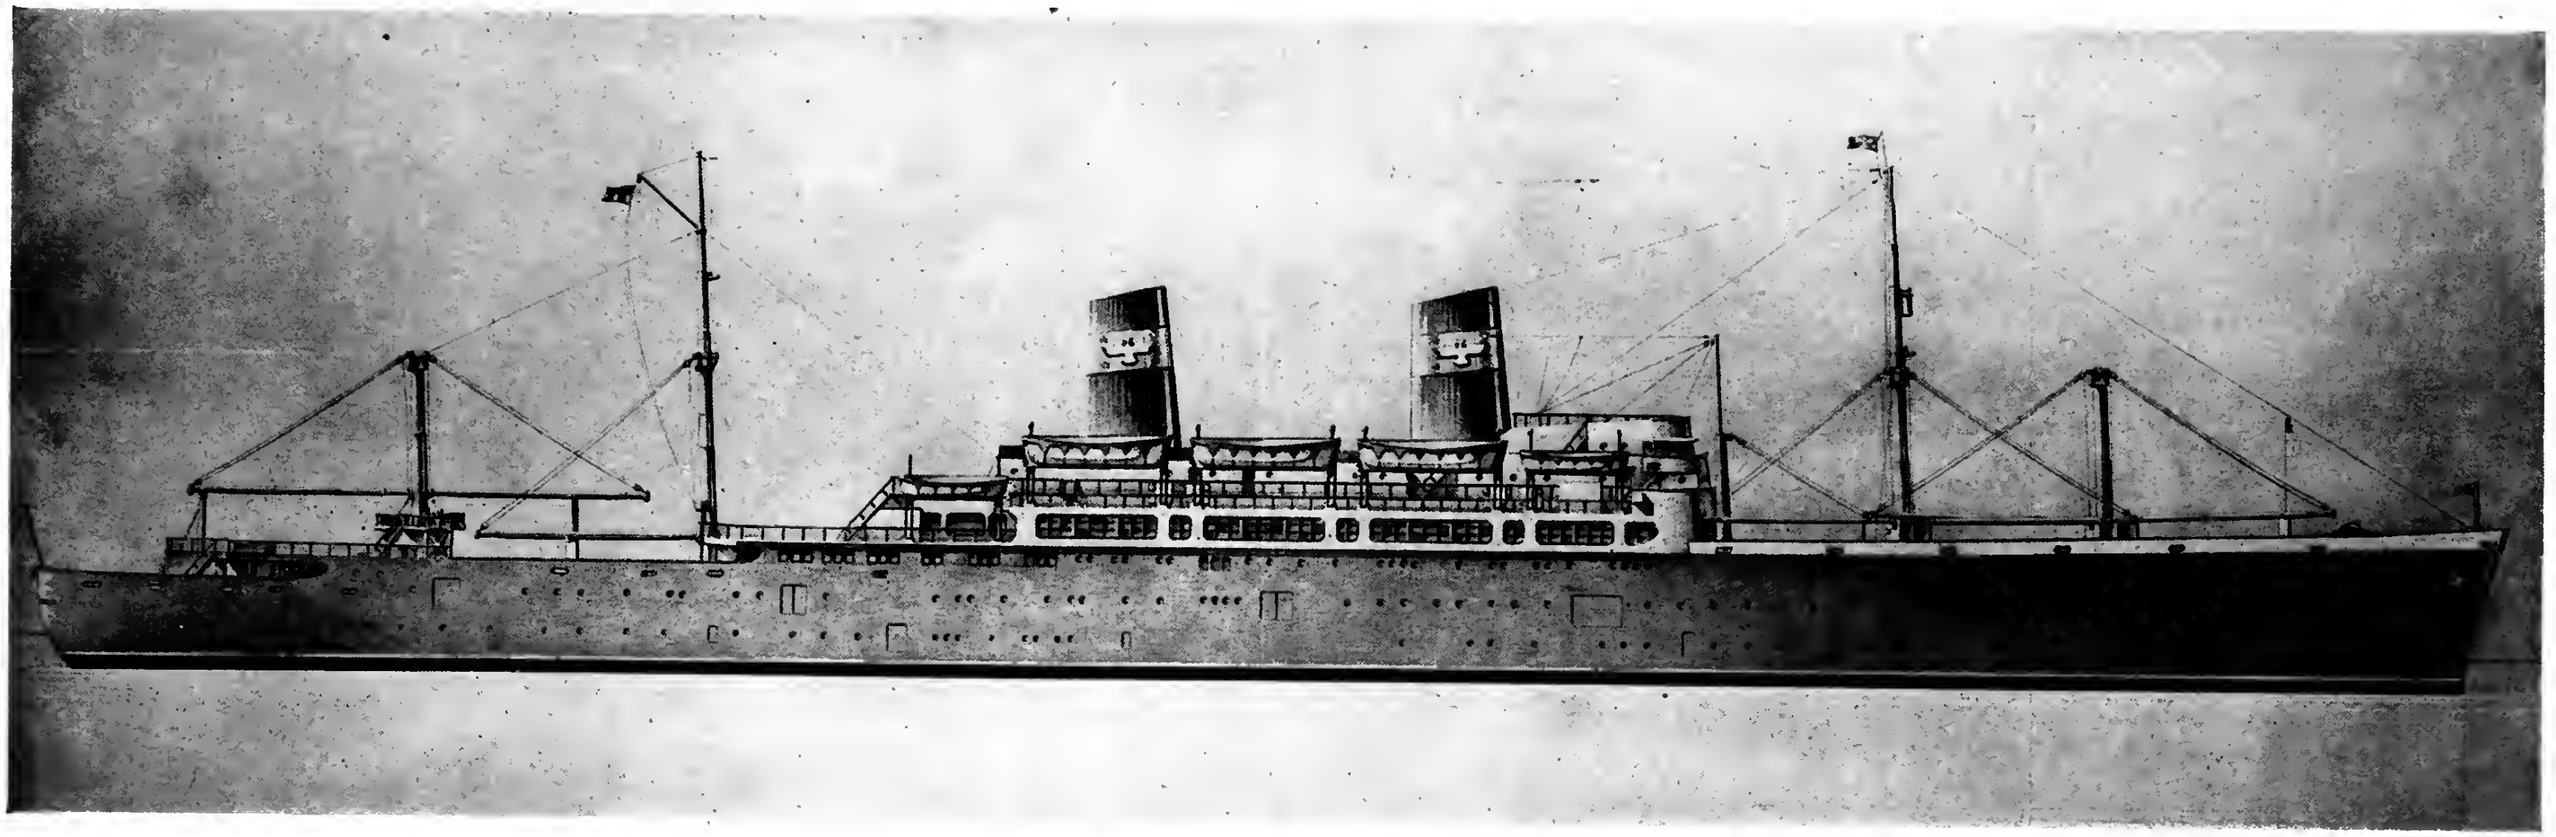
Just aft of this crew accommodation on "A" deck is the purser's office and the main cabin class entrance hall. Aft of this entrance are cabin and tourist class staterooms and at frame 160 is the tourist class entrance and purser's office. The third class passengers' entrance and purser's office is at frame 190 and aft of this a third class smoking room and lounge.

"B" Deck

From stern to frame 36 this deck is occupied by bo'suns stores, chain locker, and dry cargo hold No. 1. From 36 to 106 there are crew's accommodations, including galley and mess rooms. From frame 106 to frame 128 the cabin class dining room occupies the full beam of the hull. The galley runs from frame 128 to frame 152. A tourist class dining room takes 10 frames aft of the galley. Thence to frame 195 there are a group of tourist class staterooms on the starboard side and a complete hospital on the port side. Aft of this group of rooms is the third class dining room and the third class galley.

"C" Deck

On "C" deck from the stern aft are located: chain locker; dry cargo hold No. 1; dry cargo hold No. 2; ship's laundry port and strongroom and baggage room starboard; refrigerated cargo chambers and refrigeration machinery; ship's refrigerated stores and miscellaneous ship's stores;



P-2 PASSENGER LINERS

Artist's conception of the converted P-2 liners being completed at Bethlehem Alameda Yard for the American President Lines. Each of these two passenger liners will cost seven and a half millions for the conversion items, in addition to the seven and a half millions already expended on the vessel as a Navy transport, so that the total cost will be approximately $15,000,000 for each ship. On launching they will be christened PRESIDENT CLEVELAND and PRESIDENT WILSON. The present expectation is that the two ships will be ready for delivery in July and September, 1946.

General Characteristics of P-2 Hull

Length O. A.	608′ 11″
" W. L.	590′ 0″
" B. P.	593′ 2″
Beam Molded	75′ 6″
Depth Prom. Deck at Side	61′ 6″
" Upper Deck at Side	52′ 4″
" "A" Deck at Side	43′ 6″
Draft Scantling	26′ 0″
" Subdivision	30′ 0″
Displacement Loaded	22,380 Tons
Cargo Deadweight	10,550 Tons
Refrigerated Cargo	621 Tons
Normal Speed	19 Knots
" Power	18,000 shp
Max. Continuous Power	20,500 shp
Cabin Class Passengers	182
Tourist Class Passengers	144
Third Class Passengers	224
Total Passenger Capacity	550
Total Crew	338

and third class passenger accommodations.

"D" Deck

This is a partial deck starting at the after bulkhead of hold No. 2 and running through hold No. 3 and the refrigerated cargo spaces to the forward bulkhead of the forward machinery space. At the after bulkhead of the propulsion motor rooms this deck forms a platform in the after holds aft to the after peak bulkhead.

Boat Deck

The first deck in the midship erection above the promenade deck will carry five boats port and starboard on Welin McLaughlin davits, fitted with Welin electric boat hoists. These 10 boats are approved to carry a total of 934 persons. One boat on each side will be fitted with a gasoline motor and will be able to tow the others. Quarters on this deck provide accommodation for: the principal deck officers; the officers' pantry and mess; the radio room and radio operator's room; and the emergency generator room.

Public Room Design

There will be ample need for a very intelligent use of the interior decoration art in the public rooms of this vessel. In the tourist and the cabin class dining rooms, for instance, where the width of the room is the beam of the ship, or approximately 70 feet clear, and the ceiling height is less than 8 feet, there is quite a problem to make the rooms seem to be airy and spacious. The same is true also of the lounge, smoking rooms, and marine veranda on the promenade deck, where the ceiling will be not much higher. The stair halls will give opportunity for some beautiful effects and no doubt will be used to great advantage for first impressions on passengers at the entrance lobbies.

An extension of the promenade deck aft would have given opportunity for more deck promenade space and more spacious public rooms for the cabin class passengers. However, as in all cargo passenger liners, the design problem becomes a compromise between passenger accommodations and cargo handling, and in this instance the arrangements for cargo seem to have been worked out very thoroughly.

When delivered, these vessels will be the largest commercial ships ever built on the Pacific Coast, and all of these experts will be watching with keen interest the finish and the neatness of Pacific Coast craftsmanship in the passenger accommodations for ships of this class. The machinery installation is the same as that used in several identical hull Navy transports already delivered by the same shipyard and tested satisfactorily in many transpacific voyages.

Of interest to the entire industry is the promise for the future of the merchant marine contained in the third and fourth paragraphs of President Truman's Christmas Message to Admiral Land.

THE WHITE HOUSE
WASHINGTON

December 10, 1945

Dear Admiral Land:

During the past five years Christmas has come to men of the Merchant Marine as they huddled behind blackout screens, riding loads of ammunition, oil and supplies for War.

Now, with the aid of Divine Providence, our Merchant Marine can sail the seas with lights on. When the job of bringing the troops back home is finished, the Merchant Marine will move the goods of Peace.

During the black years of War, the men of the Merchant Marine did their job with boldness and daring. Six thousand were killed or missing in carrying out their duties.

In memory of those men, and in the interest of our Nation, the United States must carry out the bold and daring plan of Franklin D. Roosevelt for a Merchant Marine of the best designed and equipped passenger and cargo ships, manned by the best trained men in the world.

In view of the magnificent job the Merchant Marine has done, the re-affirmation of that pledge is the best Christmas message we can give.

Very sincerely yours,

Harry Truman

Vice Admiral Emory S. Land
Administrator
War Shipping Administration
Washington 25, D. C.

Reemployment Problems In Shipyards

(Continued from page 5)

noteworthy, however, that a surprisingly large number of veterans have apparently decided not to attempt to return to the shipyards. They seem to be going back to the work they followed before coming to the shipyards or to be turning to new fields that will utilize new skills learned while in the Armed Forces.

The spasmodic nature of ship repair operations has always presented a challenge to employers and employees alike. More than almost any other industry, daily employment fluctuations have been extreme, due to the very nature of the business. During periods of ship construction considerable alleviation of this condition has been possible in so-called "combination yards"; however, it has been my belief that the possibilities of continued transfer of numbers of employees back and forth from ship repair to new construction have been exaggerated. Experience in many such operations has convinced most observers that both types of work suffer in the long run from such tactics and that the two activities should be carried on using separate labor resources to the greatest extent possible. With respect to ship repair operations, present discussions of guaranteed annual wage plans and permanence of employment pose special difficulties for this industry. It appears that increasing problems along these lines will have to be faced in the coming years. I believe that real progress in the solution of this problem can be made provided realistic, cooperative and practical thinking is brought to bear by both sides in any argument that may arise. If, on the other hand, prejudice, emotion and false economics prevail, we may see this problem develop into the most serious threat to substantial and continued employment in the ship repair industry.

Shipbuilding and ship repair will always be dependent—for a major portion of their markets—upon foreign customers. Employment in the industry will therefore suffer in the event that costs are allowed to rise beyond levels that can be justified. Repair work on foreign ships can only be secured for this country's shipyards if costs are competitive with foreign billings. This fact must ever be kept in mind by those responsible for continued increases in the cost of labor, which is by far the largest element in the cost of ship repairs. Employment in shipbuilding and ship repairing will vary almost inversely as costs are continually pushed upwards. It should never be forgotten that foreign business depends upon our ability to compete in the world markets.

It is obvious that the size of shipyard pay-rolls is directly related to the size of the merchant marine and the Navy. Shipyards were built and are maintained to build and repair ships and of necessity they must maintain their present activity if they are to continue to operate as shipyards. That, however, does not prevent the use of their facilities in the development of other types of work within the capacity and availability of their equipment. To some extent, at least, the development of other products and services will be carried on, but it is my belief that the number of jobs created in shipyards through such extracurricular activities will not be of major importance. Presently there are too many yards and too many ships for full continual utilization of all; the number of active ships and shipyards must necessarily be reduced. The shipyard reduction will certainly depend to some extent, at least, upon the number of ships in service.

We finished the war with approximately 60 million deadweight tons in the merchant marine and a stupendous investment in our mighty Navy. National policy, economy and security, as well as the acumen, courage and disposition of our shipping industry, all are involved in the picture. Until all these factors are resolved, the extent of shipyard employment is difficult to forecast. We are on the shores of what may be a tempestuous ocean of reconversion. In the difficult days ahead we should all remember that the fundamental basis of our national, business and personal prosperity is our individual disposition to work and to produce efficiently. Efficiency, purchasing power and job security—including shipyard security—are all tied together, and right there lies the key to reemployment possibilities in shipbuilding and in our entire national economy. We have all the resources, including the man-power and the know-how, which brought this country to its dominant position of industrial world leadership and we still are capable of showing that spirit of adventure and courage by which this position was attained under our democratic system of free enterprise, the system which provided the only great reservoir of experience, intelligent management and trained personnel upon which government could draw, in the hour of emergency, for the enormous expansion necessitated by its wartime effort.

Through the last four strenuous years we added greatly to our experience, and if all of us, individually and collectively, determine to apply that experience and our basic knowledge of industry with the utmost efficiency, the possible extent of shipyard employment, of all employment, will be increased. Neither labor nor management alone can create that condition; neither can profit without the enthusiastic cooperation of the other, but both can and will profit together.

Adjustment of the size of naval and merchant fleets is necessary, but in the process of accommodating those fleets to our necessities a considerable amount of shipyard work will be required. Conversions and long-deferred repairs will present the first opportunities, involving overhaul of machinery, removal of ballast and defense features, including armament, berthing, messing facilities and passenger quarters; the opening of bulkheads and provision of tonnage openings; removal of special deck houses; installation of rigging, cargo gear and awnings; adjustment of deep tanks and piping for special purposes and various modifications required by different operators, as well as drydocking, cleaning and painting and underwater repairs.

The restoration of coastwise and intercoastal operations should provide a continuing source of employment, and increased Pacific trade, requiring additional shipping facilities and resultant shipyard service, is a possibility. The outlook on new construction is less definite but plans are contemplated for a number of new vessels for special services and passenger transportation. Obviously the maintenance of shipbuilding operations is essential to the preservation of the skills necessary both in time of national emergency and to maintain a modern fleet of vessels capable of meeting competition.

Low Pressure Evaporators

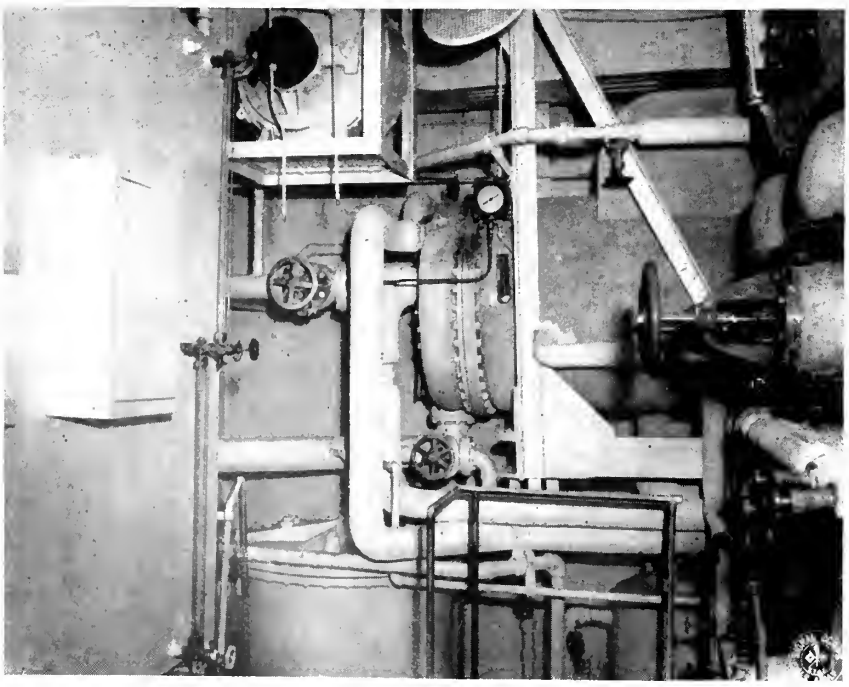
They Helped Make Freighters Into Troopships

By George H. Harlan

The problem of hauling American troops to our far-flung fighting fronts in ships which were never originally built to carry passengers was directly connected with the problem of fresh water supply. The solution hinged upon the ability of the ship either to carry sufficient supplies of water to support the additional passengers or to produce an adequate supply in an economical distilling plant which could be continuously operated while troops were aboard.

The answer lay in low pressure evaporators, the cost of installation of which compared favorably with the cost of installing adequate tanks to supply the passengers' requirements for the long voyages undertaken while occupying but a small fraction of the space required for such tanks. The water producing and purifying plant under discussion occupies a total of 3000 cu. ft. of space aboard ship, which is the equivalent of a tank holding a little more than 83 tons of water. This plant alone is sufficient to supply 1200 troops with water for an indefinite length of time on a basis of the minimum requirement of five gallons per man per day. This figure includes the water that the man would require for drinking, for culinary purposes, and for his share of hospitalization during his voyage across the ocean. His washing water would be salt unless the ship had surplus fresh water aboard. To carry the required amount of water for 1200 men in tanks for a 30-day trip would require 21,500 cu. ft. of tankage which would have to be subtracted from valuable store and cargo spaces. However, on ships where the steam supply is taken from the boiler directly, anywhere from 5 to 10 per cent of the volume of water produced would be required for additional fuel oil for evaporator operation. On ships with an auxiliary exhaust line carrying a back pressure, heat is used which would normally be wasted in the overboard discharge of the condenser, hence additional fuel space requirements are none. The space savings feature speaks so favorably for the evaporator plant that it was adopted on all ships where additional water supplies were required in any quantity whatsoever.

Distiller condenser (center), test tank (left), double effect evaporator (right).
(Official U. S. Signal Corps Photo.)



The typical distilling plant used aboard transpacific troopships throughout the war was a double effect evaporator of the low pressure type which distilled an average daily output of 80 tons of water. Through numerous heat transferring units, the low temperature steam employed to operate the plant is made to work at maximum efficiency to render the entire installation a very economical one to operate.

In the case of ships which are fitted with steam auxiliaries, the supply steam to heat the water in the first effect is taken from the auxiliary exhaust line and reduced down to a pressure of approximately four pounds per square inch gage. But on ships of more recent design, which for the most part have electric auxiliaries, the steam is taken from the desuperheated steam line from the boiler and reduced down to the required pressure by several reducing valves. Before this desuperheated steam is taken into the evaporator it passes through a desuperheater flange which assures saturation of the steam by injecting water into it through 36 holes 1/16″ in diameter, in a ring around the pipe. The desuperheater also prevents steam temperatures in excess of 227° F., for at temperatures exceeding 240° F. a very hard scale forms on the tubes which is difficult to remove.

The sea water feed to the evaporators is usually taken from the sea chest used for fire lines and sanitary service. It first passes through the distiller condenser and is then discharged overboard, the feed water to the evaporator being obtained from this overboard discharge by means of pumping. The evaporator feed water is then used as a cooling medium in the air ejector condenser where all non-condensable vapors from the distilling condenser are removed. Steam to the air ejectors is supplied from the auxiliary steam line. After the feed water has been

used as cooling water in the air ejector condenser it is used in the second effect feed heater to partially cool the vapors made by the first effect of the unit. In this way the feed water gradually picks up heat as it makes its way to the first effect of the evaporator. From the feed heater the sea water enters the first effect as feed, where it is vaporized around a nest of tubes which employ the low pressure steam as a heating medium.

The vapors produced in the first effect are cooled by the feed water in the feed heater which is placed over the tube nest entrance to the second effect of the unit. Feed water not evaporated in the first effect becomes feed water for the second effect, and at this point it is evaporated by the vapors from the first effect. The evaporation from the second effect, plus the condensation in the heating coils for the second effect, is then directed to the distiller condenser where the cool incoming feed water from the sea condensed them.

Condensate drains from the air ejector condenser and first effect tubes, being the total condensate of all boiler steam to be fed to the unit, are piped to the auxiliary and main condensers. Water not evaporated, which is a concentrated brine solution, is diluted with the overboard discharge of the salt water circulating pump and thus sent back to the sea. The brine pump had to be located quite a distance below the evaporator in order to provide proper submergence.

The distillate produced by the distiller condenser is then pumped into the fresh water test tank. This tank holds 1000 gallons of water, and is divided into two sections, each one holding 500 gallons. A salinity indicator was placed at the entrance to the test tank which sounded an electric horn if the salinity exceeded 0.3 grains of salt per gallon. A tank which was very popular on troopships was designed by M. T. J. Garlinger of the San Francisco Port of Embarkation, and was so arranged that the operator, upon hearing the salinity horn resound, could immediately change over his tanks with the operation of but one lever which controlled four valves. This not only saved time but it also prevented the back-fouling of good water already made.

After the distilled water is tested in the tanks, it is filtered and sent into the fresh water system. It receives further treatment when used for domestic purposes, which will be discussed later on in this article.

Low pressure evaporators require a great deal of care and skill in their operation to assure the efficient production of water. They will not make their rated capacity unless the personnel in charge have been given preliminary training in their operation. An evaporator tender has a very sensitive plant to care for, and should be given detailed instruction in operational procedures. Plants which are attended by trained operators will produce their rated capacity and have fewer lay-up periods than those operated by novices.

Proper operation of the distilling plant depends upon proper care by those persons who operate it and the absence of scale on the tubes of the heat transfer units. Presence of scale upsets the delicate heat transfer balance and cuts down the water-making capacity of the unit. Chemical treatment of the feed water has greatly aided in the problem of reduction of scale upon the tube nests. The evaporator is no more nor less than a boiler, and treatment of the feed water is necessary. A number of preparations designed for this purpose are on the market, most of them using corn starch and some alkaline for a base. The concentrated solution is carefully stirred and is fed into the sea water entering the evaporator.

Sea water which has been distilled by low pressure evaporating sets is not necessarily potable water. A low pressure unit may remove chemical impurities from the water, but the temperatures of the vapors formed therein are insufficient to kill harmful bacteria in the water. Evaporated water on straight freight vessels is put into tanks and its use is delayed, and while thus stored it may be purified for drinking purposes by adding chemical for that object into the tank. Agitation due to the rolling

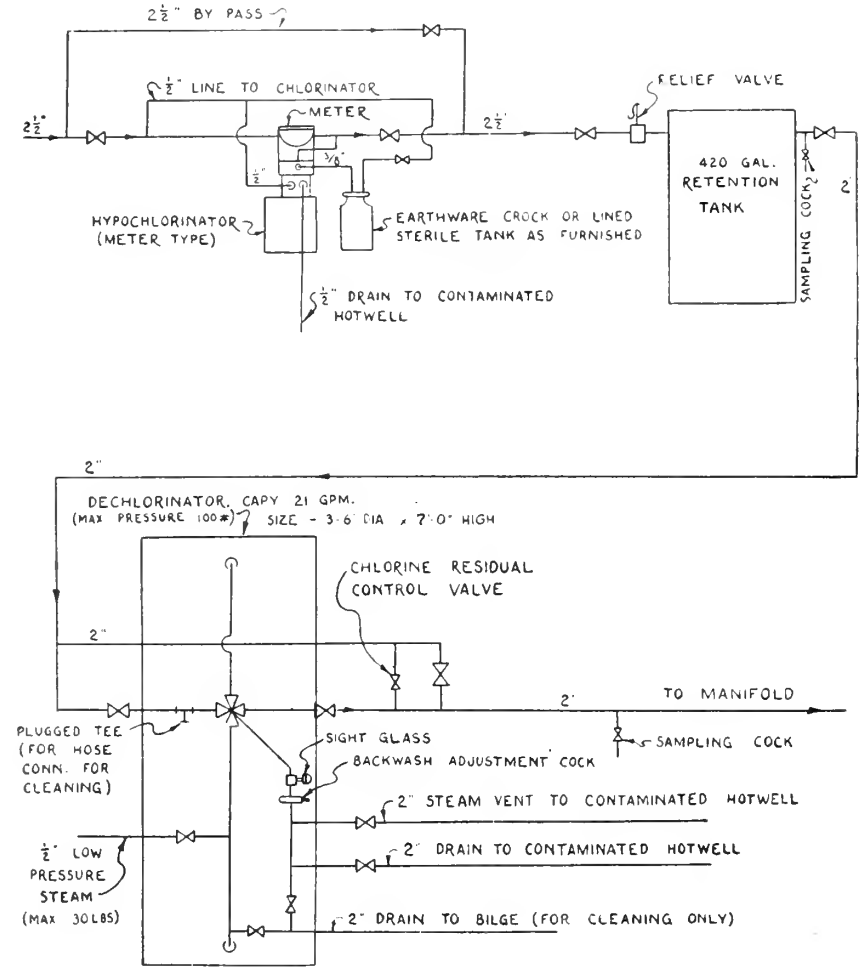
SCHEMATIC CHLORINATING SYSTEM FOR DRINKING WATER



of the ship will be sufficient within a few days to bring about a dilution which will constitute purification. The problem on a troopship is very different. Water manufactured by the evaporator set is used as it is made, and although it may be momentarily stored in tanks, the period of such storage is not of sufficient length to insure proper water treatment by the mere addition of a purifying agent into the tank. The water which is used for domestic purposes must be chlorinated as soon as it is definitely ear-marked for those purposes, and that includes the water to the troop galley, the ship's galley, the hospital and the scuttlebutt.

The most popular chlorinator used is one which consists of a chlorinating unit, a retention tank, and a dechlorinator. The water to be chlorinated passes through a meter where it is measured, the results of such measurement being relayed to the automatic hypochlorinator which injects the chlorine into the system according to the rate of flow of the water. The concentrated chlorine solution is kept in an earthware crock or sterile tank, and drawn from there as needed by the hypochlorinator. After the chlorine has been injected into the fresh water, it flows on into the retention tank. This unit is a large tank which holds about 25 times the flow of water in gallons per minute. Here the tank is baffled so as to make four different passes, and the water so agitated is assured of adequate mixture with the concentrated chlorine. From the retention tank the water proceeds to the dechlorinator unit, which is a device for removing the chlorine taste from the purified water. The dechlorinator is essentially a filter, and uses graded anthracite coal, charcoal or carbon, or a combination of these ingredients in its filtering system. The unit is a steel tank with a "baked on" enamel interior and is fitted with a small steam line for sterilization purposes and water service for cleaning.

The combination of low pressure evaporators and chlorinators was the answer to the problem of converting freighters into troopships. It sufficiently augmented the fresh water supply of the cargo carrier to make it self-sufficient in supplying fresh water to troops, existing tanks in the vessel constituting a reserve supply only. With proper care but few breakdowns were experienced in actual operation.

In peacetime operation on vessels where fresh water demands far exceed the ship's economical carrying capacity low pressure evaporators will do the work of making the ship's reqirements the same as they did during war.

Special Locomotive Carriers For Russia

By David Johnson

With the concern of the industry focused on conversion jobs for special services, the experience of the architects and builders in developing a locomotive carrier is of current interest, particularly insofar as it relates to bracing and strengthening the vessel.

The European and Asiatic devastated countries will need many locomotives and other heavy equipment, and specially designed ships will often be needed. The experience of designer and builder will be helpful to others.—Ed.

IN DECEMBER, 1943, the office of Joslyn and Ryan, Naval Architects, acting as design agents for Poole, McGonigle and Jennings in Portland, Oregon, was commissioned to convert five diesel motorships for the U. S. S. R., under auspices of the WSA, to carry locomotives from Portland, Oregon, to Russian ports.

The vessels were all of similar design, built in the U. S. S. R. as lumber carriers. Their principal dimensions are as follows:

Length O. A.	364′ 0″
Length B. P.	347′ 8″
Breadth	51′ 6″
Depth to main deck	27′ 3″
Displacement	9500 Tons at 24′ draft

Inasmuch as these ships are single deck vessels they were ideal for the purpose of transporting, with the exception of being a little small.

After conferences with Mr. V. I. Neganor of the U.S.S.R. Purchasing Commission and William H. Clark, operating manager for Moore McCormick Lines of Portland, work was started on preliminary plans and submitted to Mr. W. L. Martignoni of the WSA.

Basically the requirements were to provide stowage for 18 locomotives and tenders, approximately half to be in the hold and the remainder on deck.

Means were to be provided for shifting locomotives and tenders in the hold. This work was to be accomplished without too greatly altering the ships so that when the transporting of locomotives was completed the ships could be returned to service without again making extensive alterations.

No plans of the vessels were available, having been destroyed during the war. So it was necessary to lift the lines as well as the structure itself. The lines of the vessel were needed to satisfy ourselves of flooding curves, stability, etc., as well as to determine clearances for stowage. As soon as a number of dimensions had been lifted it was evident that it would be a tight squeeze all around if these ships were to be converted to carry the number of locomotives assigned to them.

Briefly the greatest problems faced were: to lengthen No. 2 hatch; devise a means of shifting locomotives and tenders in the holds; design a deck stowage that would be portable to carry locomotives and withstand huge seas with an ice load that would double the weight of the deck load.

To clarify the description of the work: while the ship has three holds and five hatches, from now on the space under each hatch will be termed a hold and numbered for the hatch.

After a number of preliminary layouts were made the best arrangement was found to be as follows: two tenders in No. 1 hold; eight locomotives in No. 2 and No. 3 holds; eight tenders in No. 4 hold; on deck two tenders over No. 1 hatch; four

Top: Looking aft from mainmast winch platform, showing outboard stowage and removable hatch sections.

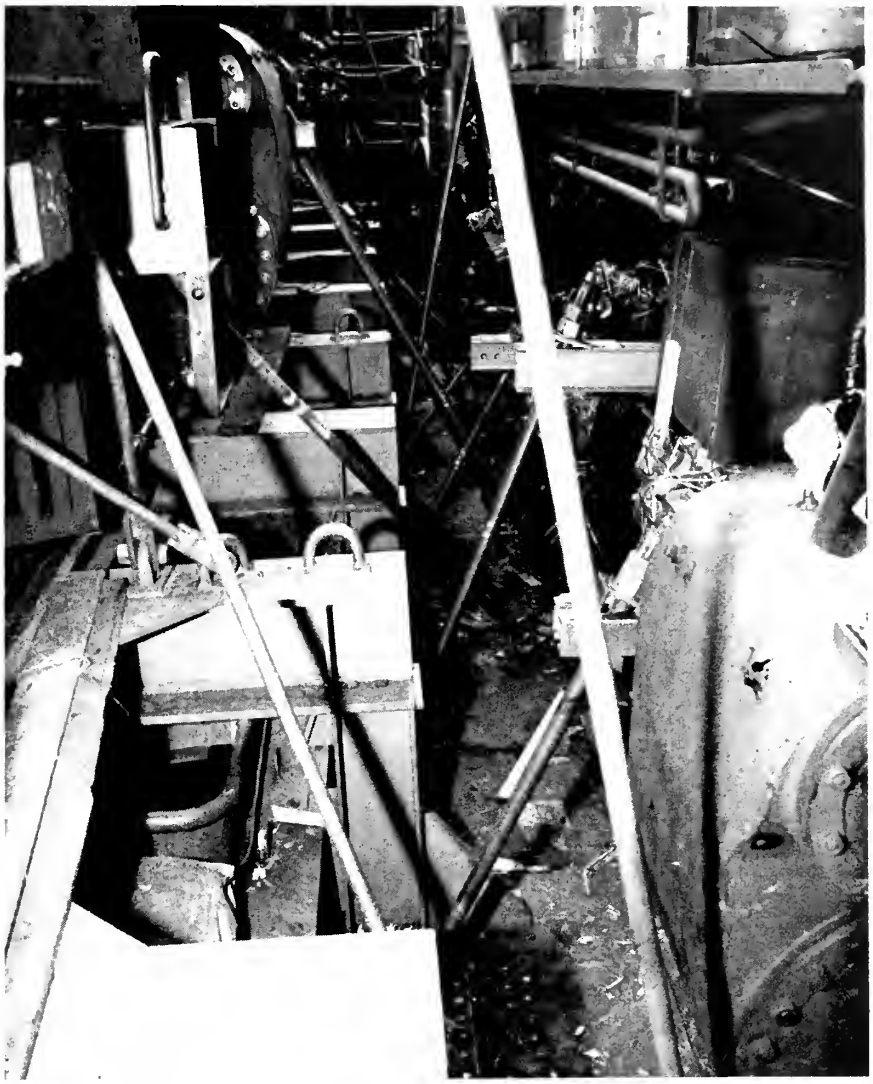
Center: Locomotive transfer table in forward hold under No. 5 hatch. Lightning holes also serve as hand holes for using grease gun on rollers, where 7 transfer tracks and 10 rollers engage each track.

Bottom: Looking forward under No. 4 hatch. This is over the shaft alley and clearance was very close.

locomotives at No. 2 hatch; two outboard and two inboard over the hatch; at No. 3 hatch two locomotives outboard and two tenders inboard over the hatch; at No. 4 hatch two locomotives outboard and two tenders over the hatch; at No. 5 hatch two tenders outboard and two locomotives over the hatch.

Following is a description of the work necessary to accomplish the stowage as outlined above: No. 1 hold was found large enough to provide stowage for two tenders with a rather large space remaining that would be available for stowage of cargo. A partial 'tween deck platform was installed on each side of the ship, extending from W. T. bulkhead 35 to frame 19. It was necessary to enlarge No. 1 hatch one frame to accommodate the tenders. Every fourth floor was reinforced with 3" x 2½" angle. One pillar, port and starboard, was installed to reinforce the longitudinal girders over. No reinforcement to the girder itself was necessary.

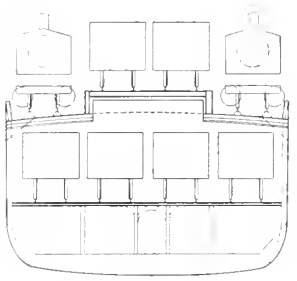
No. 2 and No. 3 holds presented the greatest problems of the conversion. First it was necessary to increase the length of No. 2 hatch, and to accomplish this it was necessary to extend it both forward and aft. To avoid making alterations too costly it was decided to let the main mast remain in its original position and remove the forward section of the winch deck house and install new winch platforms outboard. The hatch was then extended aft to within one frame of the center of main mast at frame 54. The forward end of the hatch was extended to within 12 inches of the after end of No. 1 hatch. The forward bulkhead and No. 2 hatch end beam thus forming a 13" x 16" box girder, this girder is the only tie athwartship for 75 lineal feet of hatches. To allow enough clearance for the lowering of locomotives through No. 2 hatch we had to cut watertight bulkhead 35 in the way of the hatch, this section was removed and turned forward for aft and placed one frame forward forming a jog of one frame on each side of the hatch. Watertight integrity was maintained and flood calculations altered but slightly. I believe this allowed 6" clearance each end of the locomotive,—none too much room for juggling 100 ton weights. Four pillars port and starboard approximately 14 feet on centers were required to reinforce the longitudinal girder in the way of No. 2 hatch.



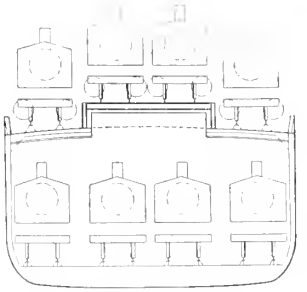
Supports over hatch and hold down fastenings.

No. 3 hold that is open to No. 2 hold is the section that was devoted to the transferring of the locomotives. The locomotives were lowered through No. 2 hatch to the center tracks and rolled aft from this position on the transfer tables. Then they were rolled transversely outboard to another set of tracks and then rolled forward. These transfer tables or sleds were fitted with seven pairs of channels running transverse to the tracks. These channels form structural members for the sled and also a means to support seven rollers to each set of channels, or 49 rollers per sled. The rollers engage a tee section fitted close to the tank top forming a transverse track for the sled to roll on. After two locomotives had been placed outboard on each side of the ship these sleds are dogged to the tank top with 28 dogs. These dogs are quick acting with a wedge type socket. The dogs were designed to take twice the combined load of a locomotive and sled, having in mind the ship rolling 30°; this meant that all loads are doubled, plus the normal safety factor added. With the outboard locomotives all in place two stationary sleds are lowered to No. 3 hold to fill the void left by the transfer sled at the two center tracks. The stationary sleds are fastened to the transverse tee sections by fitted bolts and are very similar to the transfer sled, less the dogs and the rollers. After this is accomplished the last four locomotives to be lowered are placed on the inboard tracks.

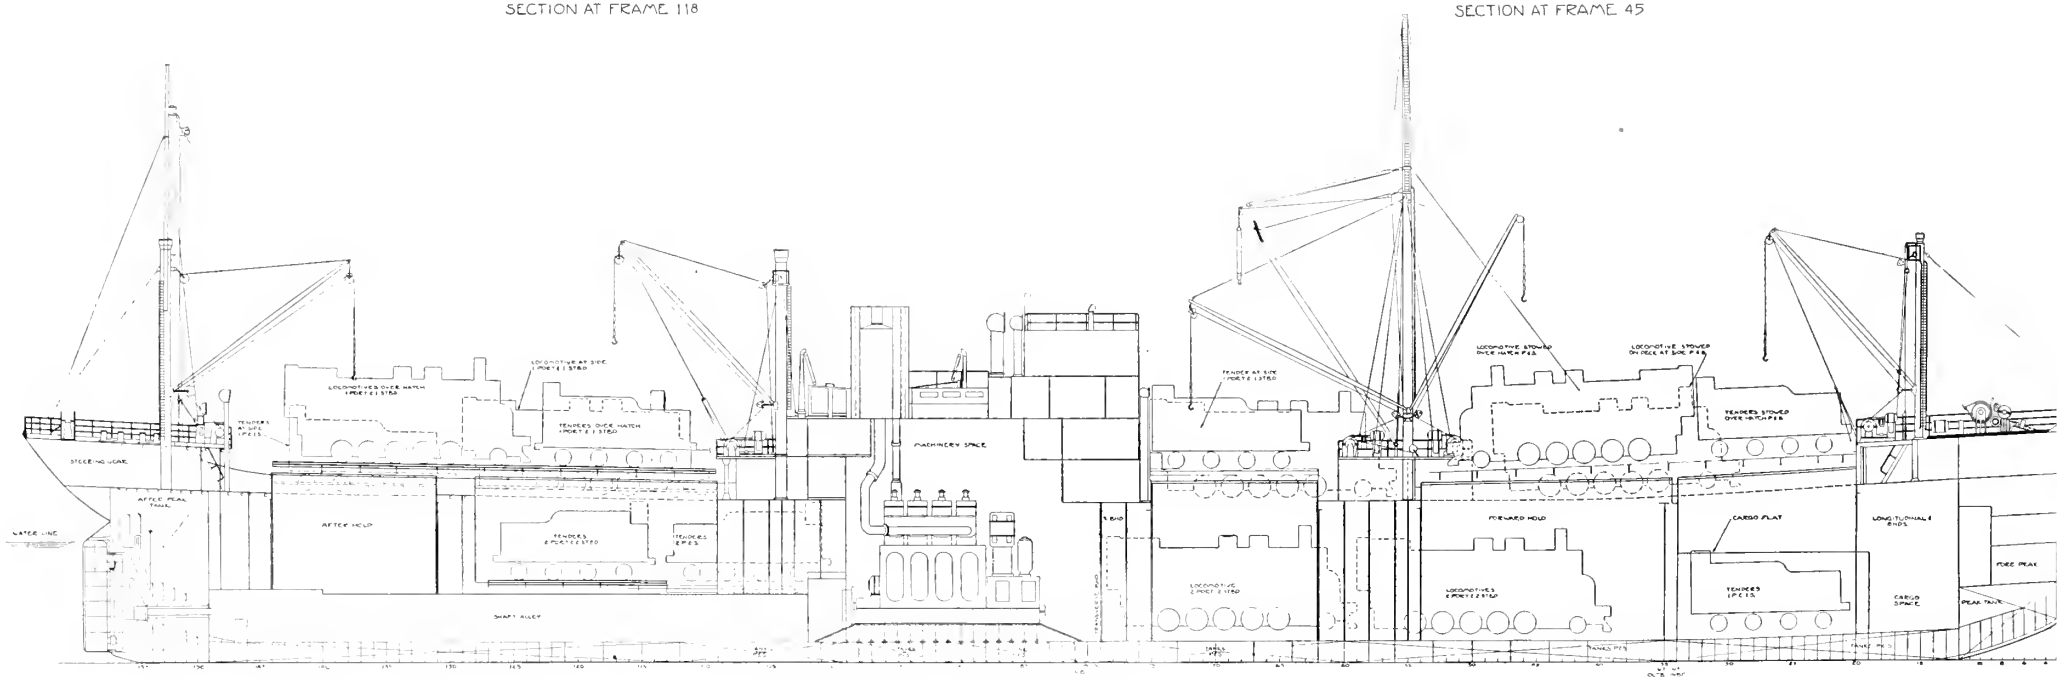
Inasmuch as the locomotive is some 40 odd feet long it was necessary to omit pillars under the deck in the



SECTION AT FRAME 118



SECTION AT FRAME 45



Profile and Sections Showing Longitudinal and Transverse Stowage.

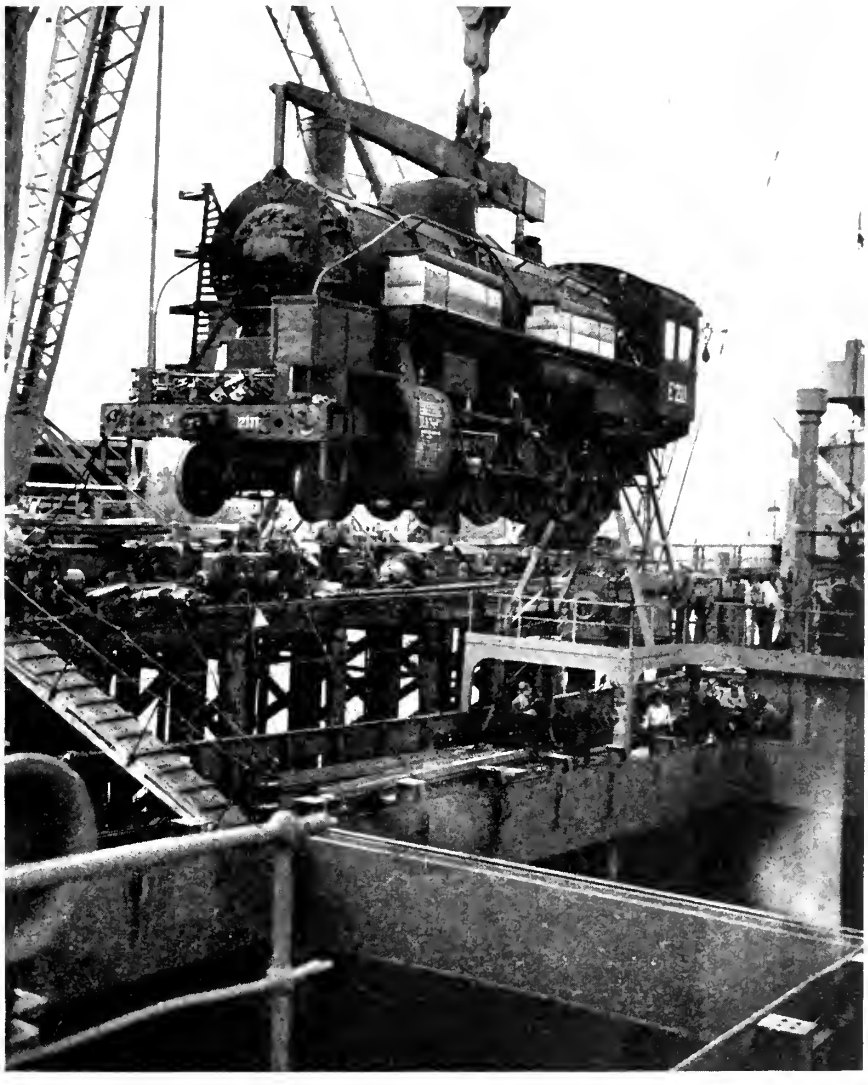
way of No. 3 hatch, so a 12″ x 30.6 pound rider plate was added to the existing girder and additional stiffening to the floors in the way of the longitudinal tracks and transverse tee sections was added.

No. 4 hold was a different problem. It was necessary to install a platform over the top of the shaft alley to gain the necessary transverse space for transferring and spotting the eight tenders that are stowed in this hold. This platform was erected by using the shaft alley as a center line support and in addition a lattice support of 5 x 5 x 16 lbs. wide flange H columns with diagonal bracing was placed approximately 11 ft. to port and starboard of the center line at every third frame. This platform was framed with 8″ wide flanged beams running transverse and fore and aft, 4″ x 3″ angles were used for racking braces. The purpose of this plating was to provide walkways. Two portable sections similar to hatch covers 12 feet x 13 feet are provided in the platform directly below the hatch. Thus two sections, each 9 feet high by 53 feet long by about 22 ft. wide port and starboard of the tunnel, are available for dense cargo. At one time in the development of the plans it was considered making this space into liquid cargo tanks, but on receiving information that Russia was to receive a large amount of aluminum ingots on Lend-Lease the cargo tanks were discarded.

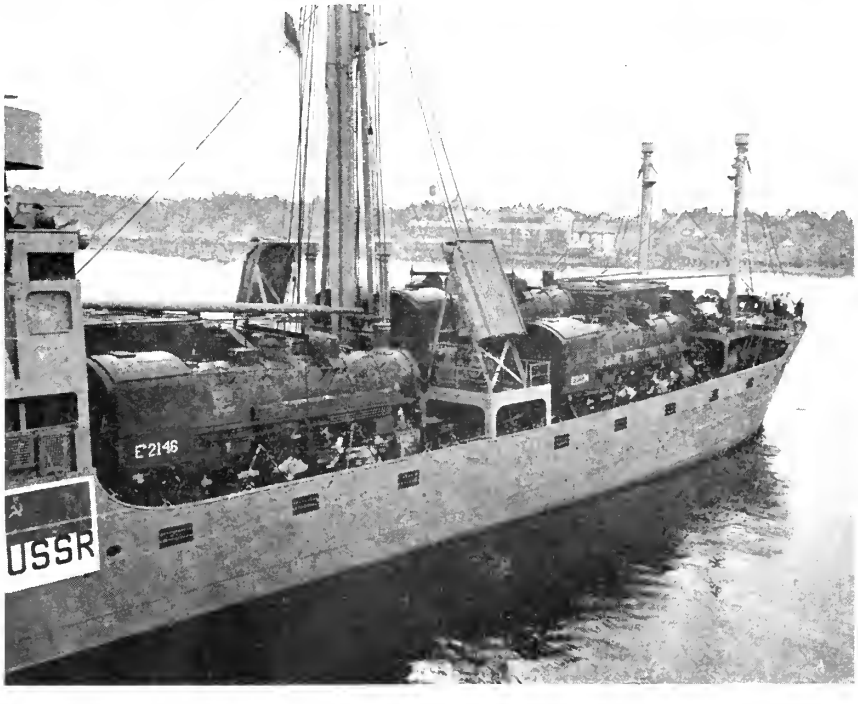
The transfer sleds for the tenders are similar to the sleds described in No. 3 hold, with the exception of size. It was necessary to enlarge hatch No. 4 six frames. Four 10″ pillars were used in holds No. 4 and 5 to compensate for deck loads over.

No. 5 hold was not altered, except for the pillars mentioned above.

To give some idea of the precision shipfitting and engineering required on this job clearances were so close that it was recommended the hand rails on the sides of the locomotive cab be removed on those to be placed in the hold. Stevedores on loading the first ship saw fit to overlook this suggestion. Needless to say they had to be removed and the bolts that were welded to the cab protruded about ½″. As the locomotive rolled down the tracks these bolts just failed to clear the pillar and had to be cut off. At another time a shipfitter must have misread his rule and a pillar was out ⅜″ and it had to be moved. In No. 4 hold at hatch end-



Transverse box beam between Holds Nos. 1 and 2 and raised winch platform. Forward end of ship, showing deck load and fastenings.



beam 109 the electricians were running a wire-way that was about 1½" deep, and this had to be moved.

Rather than upset the normal longitudinal strength of the ship it was decided not to increase the width of any hatches. So, the best arrangement in designing the hold stowage was to locate the two inboard rails as close as possible, and when No. 7 locomotive, which was next to the last to be put in place, was lowered and in a stowed position there was just 10 feet 11 inches of hatch opening left to lower locomotive No. 8, whose greatest width at the cylinders was 11 feet 1 inch. This was a tricky operation for the crane operators and they certainly deserve praise for a neat job.

In developing the stowage for the deck we had to keep in mind that everything over the hatches had to be portable and light enough to be handled by ship's gears.

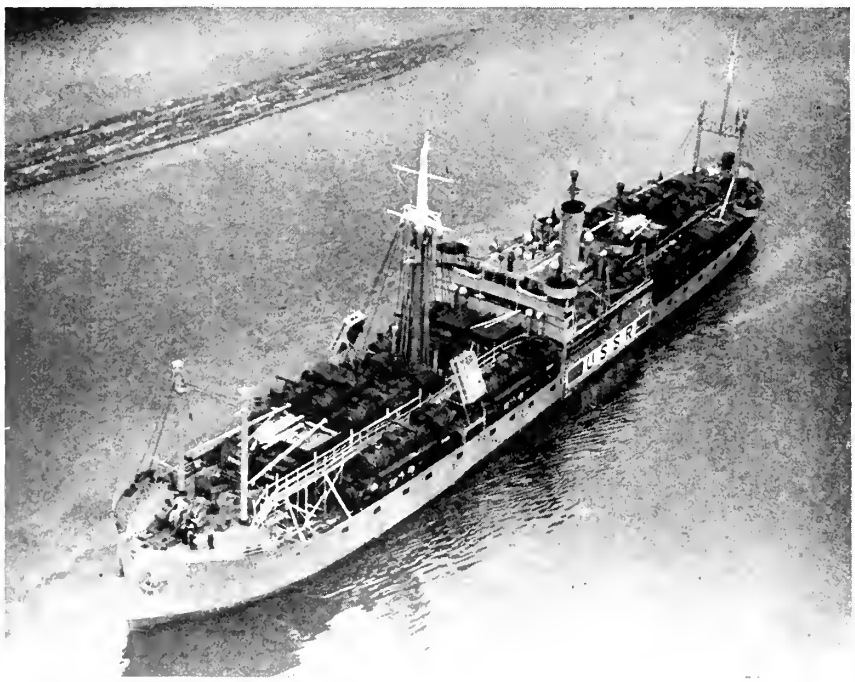
The peak on the center line of the hatches was cut down to level and hatch beams transposed or inverted, thus gaining a few inches of vertical center of gravity on the deck loads over the hatches.

The transverse beams of the hatch were fabricated H sections with a 13" x 30.6 pound plate web and a 15" x 40.8 pound plate flange and the ends placed on 10" x 10" wide flanged columns on every third frame. The deck beams below these third frames are reinforced by additional reverse tee bars 10½" x 8¼". These transverse beams were bolted each end with four 1" bolts to each column. By using a wedge system on the column and beams these bolts are theoretically in tension only, thus eliminating the use of fitted bolts.

Each hatch section is composed of four transverse beams with suitable longitudinal and diagonal bracing, two sets of 75 pound A.R.A. rails are fitted on top of the longitudinals. These sections were bolted together by clips and at the point of junction of the rails standard rail fish plates are used making each section a rigid unit on top of each hatch.

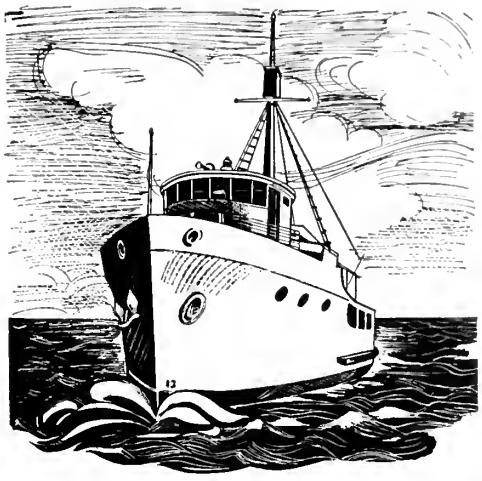
The outboard tracks consisted of a tee section welded to the decks on chocks on every third frame. The 75 pound rails were welded on top of the tee girders. It should be mentioned that these tee section girders were considered as deck reinforcing similar to a girder that would be placed below deck. At the same time the 75 pound rail sections were also considered as structural members. In fact, one of the few changes that could be made in this job would be to eliminate the 75 pound rail altogether except where locomotives have to be moved. A heavy piece of plate at the top of the tee girder could serve very nicely as a rail and dispense with the difficulty encountered in welding the high carbon steel rails to mild structural steel. At first large sections of the base flange of the rail would crack as the track was welded. This caused much concern as these ships would be traveling in just about the extremes of hot and cold climates. The designers had visions of rails breaking and locomotives careening wildly about the decks, but one of the shipfitter leadermen tried stainless steel welding rod and the problem was solved. The average time for these conversions was 45 days and the cost $1,500,000 each.

This series of conversions proved to be most successful and full credit must be shared with Poole, McGonigle and Jennings for their very excellent workmanship; Moore, McCormick for their know-how in handling cargoes of this type; Motor Body Corporation for the excellent work of lashing down; U. S. S. R. Purchasing Commission and their very capable engineers, and WSA for their approval and sanction for work of this type.



Aerial view of vessel under way.

Coast Commercial Craft



Harbor Tugs

These tugs, designed for Navy use, will find their way into commercial harbor work soon after completion.

AT THE SAN PEDRO, CALIF., yard of the Bethlehem Steel Company, Shipbuilding Division, four YTB single screw, all-welded steel hull, diesel electric, harbor tugs are under construction for the U. S. Navy. Two of these, named Acoma and Arawac, are now scheduled for delivery on the 11th and the 25th of January, 1946, respectively. The other two, which are to be christened Canarsee and Moratoc were launched on December 21st and are scheduled for delivery on February 1st and 8th, 1946.

These craft have the following characteristics:

Length O. A.	100′ 0″
Length B. P.	88′ 6″
Breadth, extreme, molded	25′ 0″
Depth, molded	13′ 6″
Displacement, full load	325 Tons
Mean Draft, full load	9′ 7″
Diesel Oil, full load (95 per cent capacity)	70.3 Tons
Lubricating Oil, full load	3.4 Tons
Fresh Water, full load	10.2 Tons

The steel hull is very sturdily built with an abundance of stiffeners and of cross bracing as will be noted from the sections reproduced herewith. In external appearance these vessels are typical harbor tugs, with a straight stem, a fantail stern covering a large rudder, and a long deckhouse with pilot house mounted on its forward end.

On the main deck forward is installed a large combined windlass and capstan. The windlass and capstan can be used jointly or independently and are driven through a vertical shaft and enclosed gearing by an electric drip-proof motor mounted below the deck. The controller of this motor provides for five speeds in either direction. An electric brake on the motor must hold 7500 lbs. rope pull on the capstan. The capstan is designed to handle 8″ circumference rope and develops a 5000 pull at a rope speed of 40 f.p.m. On the main deck aft a similar capstan without windlass is installed at the starboard side of the main towing bitt. This unit is used for warping, for boat and cargo handling and for emergency steering. Both capstans were manufactured by the McKiernan-Terry Corporation.

The steering gear, manufactured by the Sperry Gyroscope Company, is of the electro-mechanical wire rope drum type, capable of moving the rudder: from 35 per cent left to 35 per cent right, with not more than 12 turns of the steering wheel; from 45° left to 45° right in not more than 20 seconds at full speed ahead of the hull; and from 45° left to 45° right in not more than 40 seconds at full speed astern. A full follow-up steering station is installed in the pilot house and a non follow-up steering station at the after end of the deck house. In the event of electric power failure a throw-over mechanism transfers the system to manual operation.

Two water systems for fire fighting are installed. In one of these a 2000 gpm 150 psi motor driven centrifugal pump serves six 3½ inch hose outlets (three port and three starboard) and two monitors, one on top of the pilot house and one on the top of the deck house forward of pilot house. The other system is fed by a 300 gpm 100 psi centrifugal motor drive pump and serves four 1½ inch fire plugs, two forward and two aft on main deck. Both pumps were supplied by the Frederick Iron and Steel Company.

The machinery spaces are protected by a foam generator system in the engine room and a portable carbon dioxide system with two 50 pound bottles in the motor room.

Deck fittings for towing lines and other purposes include: four double barreled 9 inch bitts; one 12 inch towing bitt aft; one 12 inch single barreled bitt forward; one closed chock aft and two closed chocks forward all worked into the bulwark plating; one rail chock port and starboard forward; a 36″ towing cleat on main deck aft and cleats on the bulwark aft. A steel chafing strip is fitted on the taff rail all around the fantail.

In any tug the important feature is the propulsion machinery and in this tug the descriptive phrase "There's nothing much to her but her power plant" is very apt. Out of 60 frame spaces between perpendiculars 33 are occupied by machinery. Propulsion is on the direct current diesel electric system and comprises two General Motors diesel engines each direct connected to a General Electric generator. Each generator is electrically connected to a General Electric motor, and each motor drives one of the pinions of a Farrel-Birmingham single reduction gear set, the large gear

wheel shaft being directly coupled to the propeller shaft of the tug.

The diesel engines are six cylinder VEE type compression ignition, solid injection, two cycle, cooled by fresh water in a closed cooling system and arranged for electric starting using a starter winding on the main generator. Each engine is rated 480 bhp at 675 rpm and 600 bhp at 750 rpm

The generators are mounted on the same bed plate as the engine and are direct current two wire type with a normal rating of 410 K.W. at 250 volts. They are totally enclosed water cooled with motor driven ventilating fans, and pressure lubricated from the diesel engine lube oil pump. Each generator has a 500 watt 120 volt heater. Each generator shaft drives by belt a 25 K.W. d.c. two wire self-ventilated self-excited exciter. Each propulsion motor is rated 510 shp at 250 volts d.c.

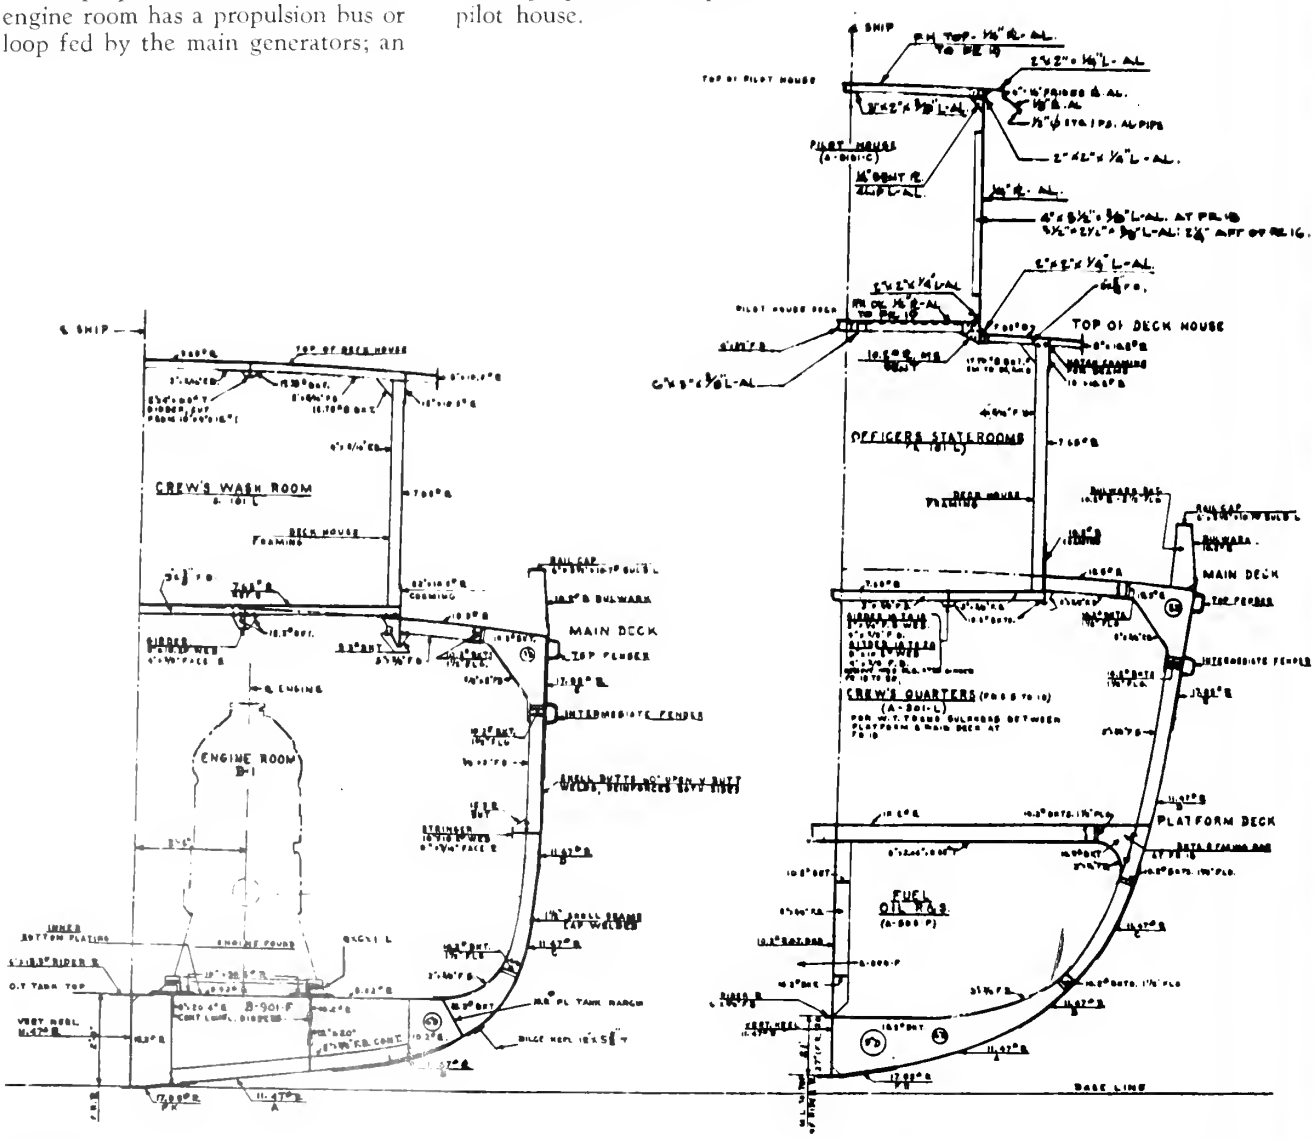
The propulsion control unit in the engine room has a propulsion bus or loop fed by the main generators; an excitation and control bus fed from either of the main exciters; and a fire pump bus fed from either propulsion generator.

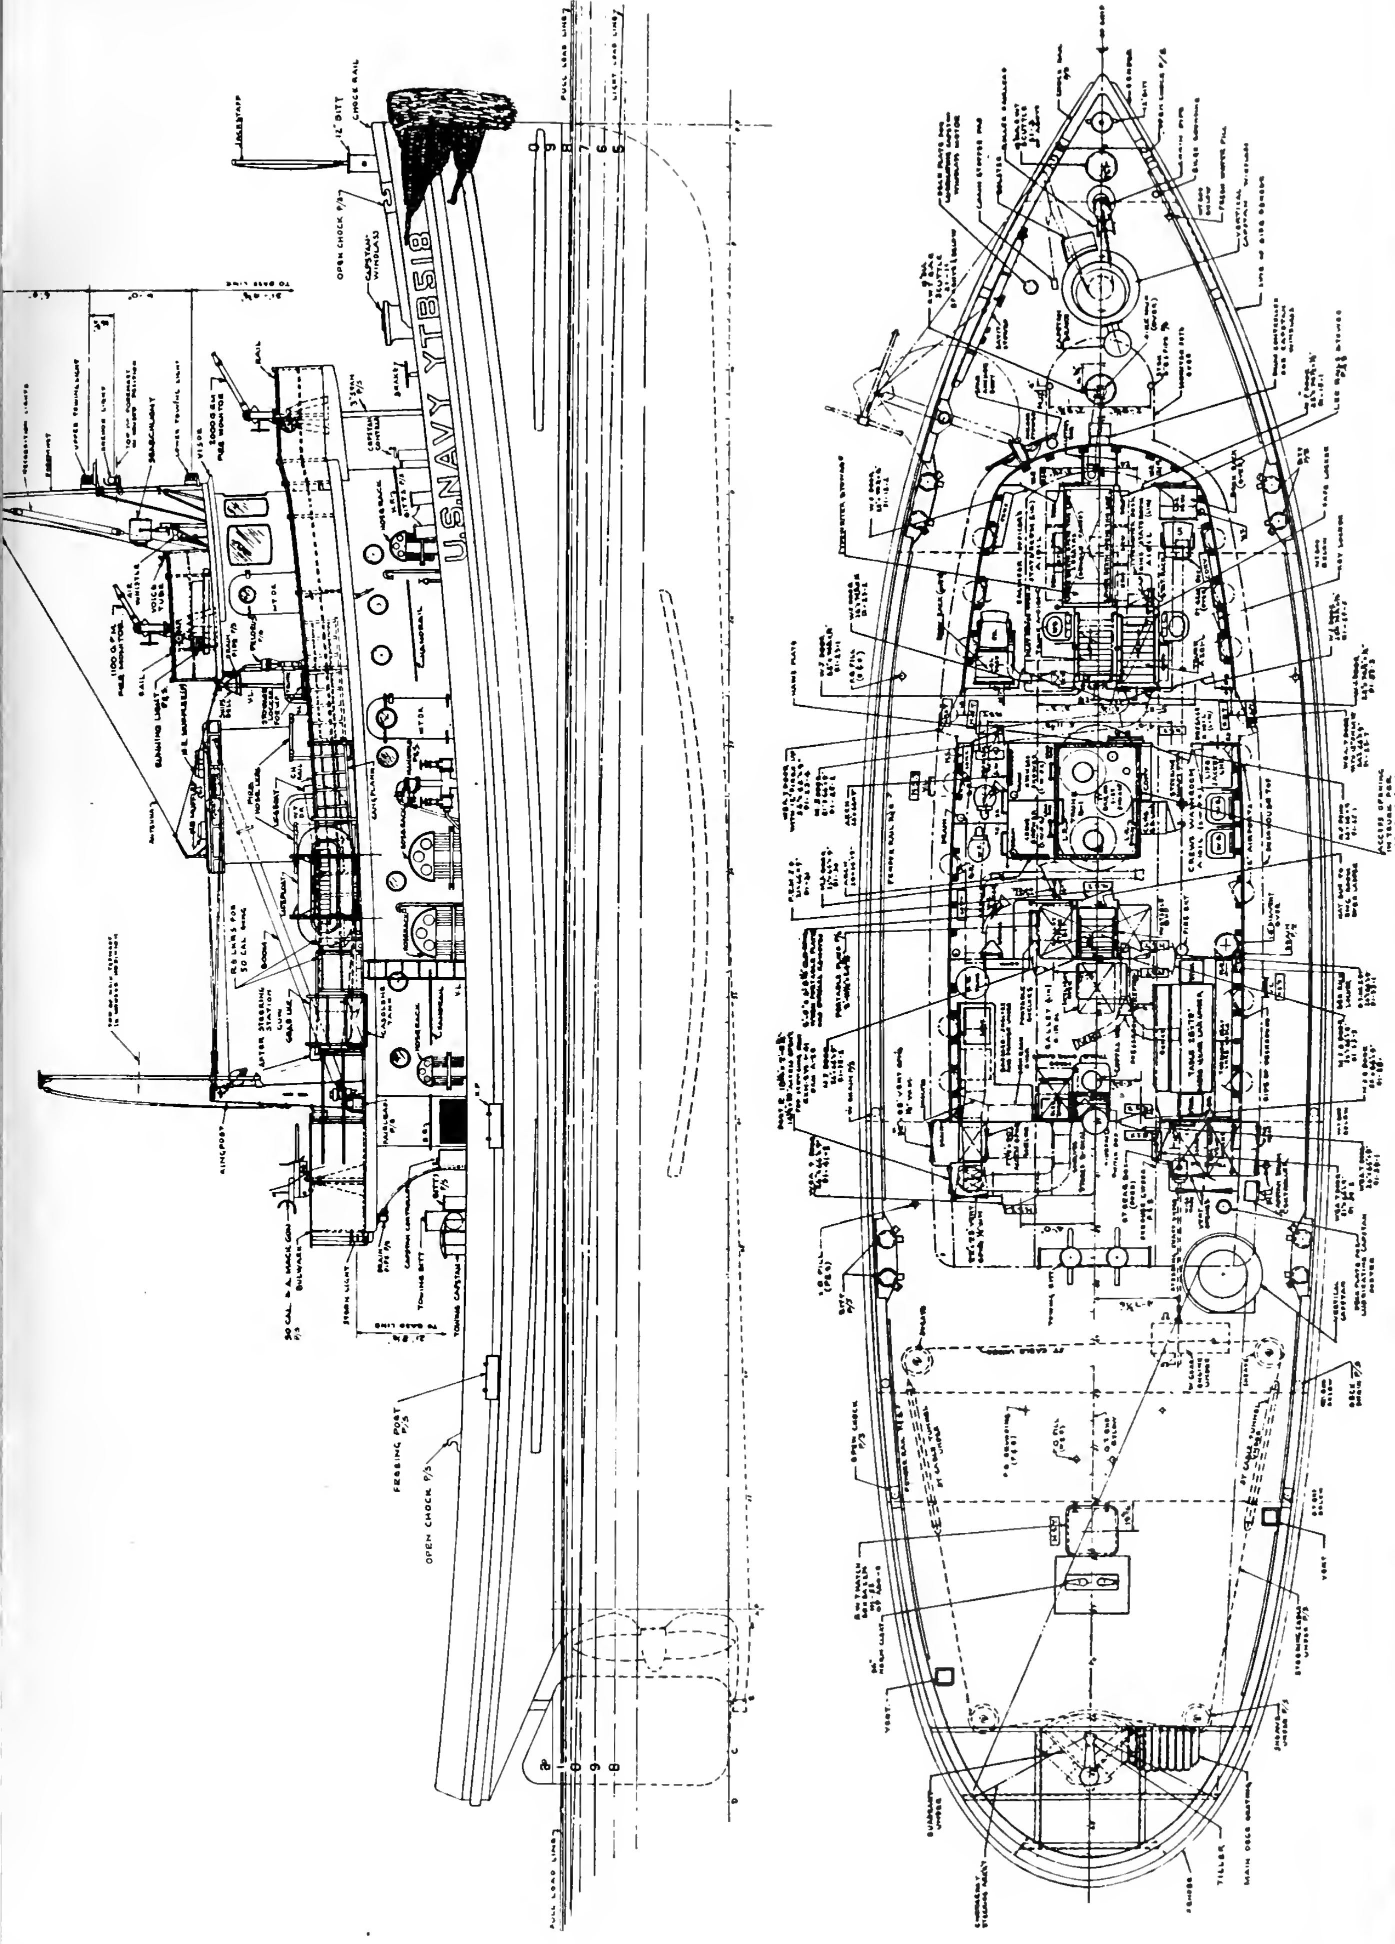
Each propulsion generator set-up switch has a "fire pump" position. The "fire pump" position on the set-up switch connects its propulsion generators together with all necessary control for fire pump service. The fire pump is started by voltage control from the propulsion generator. The field of the fire pump is supplied from the 120 volt excitation and control bus.

The propulsion control unit has an excitation transfer switch which permits either one of the main exciters to furnish ship's service power while the other is connected to supply 120 volt excitation and control power.

Two pilot house control stands are provided for remote starting, stopping and reversing, and regulation of the propeller shaft speed from the pilot house.

In addition to the pumps already mentioned each of these tugs carries a number of items in auxiliary machinery. Among these are: one 40 K.W. Buda ship's service diesel generating set with battery charging generator and starting motor, together with a Royal Switchboard Co. generator and distribution switchboard; one Williams Sales Co. auxiliary water heating boiler and controls designed to add 20,000 BTU's an hour to the hot water system; one Westinghouse Air Brake Company 20 cfm at 100 psi air compressor; one fresh water pressure system with 42 gallon tank and a Gould pump with a capacity of 10 gpm at 40 psi; one Allis-Chalmers flushing pump with a capacity of 50 gpm at 50 psi; one motor drive Kerr Machinery Co. lube oil transfer pump rotary type rated 50 gpm at 50 psi; one Gould rotary pump for fuel oil transfer 50 gpm at 20 psi





U.S. NAVY YTB518

Consolidated Launches Fourth Tuna Clipper

The Fatima, the fourth all-steel tuna clipper to be built at Consolidated Steel Corporation's Boat Division, was launched in Newport Harbor, Sunday, December 23.

The boat was sponsored by Mrs. Rosa, wife of Capt. Joe F. Rosa, skipper of the Fatima. Maid of Honor was Miss Josephine Cutri.

The Fatima is 99 feet long and has a refrigerated capacity of 200 tons. Several other fishing boats are under construction at Consolidated's 21-acre boat yard at Newport.

Steel Tuna Clippers at San Diego

The fourth steel-welded tuna clipper launched by National Iron Works since that pioneer San Diego concern began its boatbuilding activities early in 1945 slid into San Diego Bay on December 20.

Christened the Pico—for the island in the Azores from which many members of San Diego's Portuguese colony migrated to this country—the 70-foot vessel will make her maiden voyage early in 1946 for the High Seas Tuna Packing Co.

Her owners are Manuel H. Freitas, Manuel F. Soares, Joe Soares, Tiago Goulart, V. E. Sherwin and Paul E. Lovett. The craft has a fish-carrying capacity of 74 tons.

The launching ceremony followed the company's annual Christmas party for its 245 employees, who were presented 20-pound turkeys for their holiday feasts.

With Arthur Ponsford as master of ceremonies, the program included remarks by Anderson Borthwick of San Diego's harbor department; Superior Judge Gordon Thompson; William Robinson, assistant manager of High Seas Tuna Packing Co.; Paul E. Lovett, boat co-owner; and C. Arnholt Smith, National Iron Works' president.

The Pico was christened by Louise Freitas, daughter of co-owner Freitas. She was attended by Mary Soares, daughter of Joe Soares, as maid of honor, and by Mrs. Sherwin as matron of honor.

Ponsford declared that although in some quarters pessimism has been heard over the possibility that the tuna fleet is being overbuilt, "the leading canners do not think so."

"America will have an insatiable appetite for tuna, the most delectable product of the sea, and the industry's goal in 1946 is an all-time record of 5,000,000 cases," he said. "This year's output in San Diego and San Pedro will total 3,400,000 cases. In dollar value, tuna is the greatest fishing industry in the world."

National Iron Works has built three 52-foot steel clippers, and has under construction two 105-footers.

Coastal Cargo Vessel Biak

Above: The motorship Biak, shown here on her trial trip, is the second vessel to be completed by the Albina Engine & Machine Works, Inc., of Portland, Oregan, for the Netherlands East Indies Government. The contract calls for delivery of 20 coastal cargo vessels each having an over-all length of 180 feet 7 inches, a beam of 29 feet 0 inches and a depth of 10 feet 6 inches.

Salvage

In Victoria (Crew Claims), U. S. Dist. Ct., Southern Dist. of New York, 1945 A.M.C. 1199, this cause of libel concerns both claims for wages and claims for salvage. I shall only deal with the discussion of the salvage claim. The Victoria was an Argentine tank vessel which was the object of a torpedo attack on April 17, 1942, when it was approximately 360 miles from the City of New York and about 300 miles from the coast. The torpedo tore a hole about 25 feet in width and 25 feet in height under the waterline on her port side near the bow, opening up tanks 1 and 2. The captain ordered lifeboats to be made ready for use, and approximately an hour and a half later she was struck again by another torpedo which tore another hole about 25 feet wide and 25 feet high under her waterline near her stern, opening up tanks 6 and 7. The captain thereupon ordered the ship to be abandoned. Lifeboats were all ordered away and were rowed or sailed away until they lost sight of the vessel and each other. Approximately 6 hours later the United States Destroyer Owl sighted the Victoria. She went alongside the drifting derelict and placed men aboard who were able to get her under way for a short distance. Approximately a day later the Owl picked up lifeboat No. 1, transferred the crew to the Victoria under the command of her Chief Officer, and took off the men of the Owl. The Victoria thereafter was escorted by the Owl and got under way to New York under her own power. Lifeboat No. 2 was picked up by another United States destroyer and the men transferred to the Victoria. The Owl was relieved by the Navy tug Sagamore approximately two days after discovery of the Victoria, which tug continued to escort the Victoria to port. The evidence leaves no doubt that the Victoria, abandoned by officers and crew without any hope or intention of returning, was a derelict and that the members of the crew of the Owl were salvors. **(The Laura,** 81 U. S. 336.) The abandonment thereby terminated the voyage and the contractual services of the seamen. Although ordinarily seamen are not entitled to salvage awards for saving their own ship because that service is a part of their duty, yet they do become entitled thereto when their ship has been abandoned without any hope of recovery. **(Mason** vs. **Blaireau,** 6 U. S. 238.)

All who were engaged in the enterprise and materially contributed to the saving of the Victoria are entitled to share in the salvage. They are not deprived of that right because another set of salvors refused or neglected to join in the suit. **(The Blackwall,** 77 U. S. 1.)

The fact that the United States Government does not seek salvage inasmuch as the vessel and the cargo were under the flag of a sister republic of this hemisphere **(Victoria,** 1942 A.M.C. 864), does not prejudice the rights of the co-salvors to their proper proportionate share of an award. **(The Blackwall, supra.)**

The award is apportionable among all the salvors; that is, the crews of the Owl, the Sagamore and the Victoria, all of whom aided in bringing the Victoria into port.

The crew of the Owl, which discovered the derelict and started her on her voyage to her destination, supplied her with compressed air to start and run her motors, assisted in making the necessary repairs and convoyed her part way to New York, would be entitled to the largest part of the award, but seeks no award.

Though the Victoria was not an uncontrolled derelict when the libellants returned as salvors, they were called upon to assist in bringing the Victoria safely into port. They made minor repairs and rendered some services in addition to those rendered by them before their ship was struck by torpedoes. This entitles them to some award, though not to a very substantial amount.

It has been stipulated that the value of the Victoria when brought into port was $1,150,000. An award of $115,000, or 10 per cent of her stipulated value, 83 per cent distributable to the crews of the Owl and the Sagamore and 17 per cent thereof, or $19,950, to the crew of the Victoria, amounting to about $500 for each member of that crew, seems reasonable to the Court. See **The Lamington,** 86 Fed. 675, 685.

Frustration of Charter Party

Henjes Marine, Inc., vs. **White Construction Co., Inc.,** State of New York, Sup. Ct., New York County, Trial Term, 1945 A.M.C. 1240. This is an action in contract to recover moneys allegedly due for the hire of a tug. Plaintiff as lessor entered into a charter agreement with defendant as lessee on March 11, 1942, whereby the latter rented a tug on a **per diem** basis in addition to furnishing their own crew and operating the tug themselves. The agreement did not specify any particular period of time for which the tug was rented, although there was a provision reserving the right in the lessee to terminate "at any time that it appears to the Government's advantage to do so." The charter hire was paid until

July 31, 1942, the day following which title to the tug was requisitioned by the War Shipping Administration. The tug, however, was continued in use on the same project and under the same circumstances as before. The War Shipping Administration appraised the tug and made a tender of such sum, which was refused by the plaintiff, following which the plaintiff accepted 75% of the amount offered to him pursuant to Section 902 of the Merchant Marine Act of 1936, as amended, and Executive Order 9054, reserving his right, of course, to seek additional compensation from the Government. Plaintiff is seeking in this action to recover the charter hire for the period beyond August 1, 1942. Defendants have set up affirmative defenses in which they allege that the requisitioning of the tug by the Government resulted in a **frustration** of the charter agreement and thereby relieved the defendants of all obligations; that the acceptance of partial payment by the plaintiff from the Government constituted an election to look to the Government for full compensation estopped plaintiff from asserting its claim in this action. The issue may be summarized by saying that the Court was called upon in this case to determine whether the Governmental seizure of the tug **"per se** occasioned an abrogation of the charter agreement between the parties."

This question was considered in **Omnia Commercial Company, Inc., vs. United States** (261 U. S. 502). In that case, the Government, for purposes incidental to the prosecution of war, requisitioned the entire output of a steel manufacturer, thereby rendering impossible the further lawful performance of an existing contract between the manufacturer and a customer. The requisitioning of the subject matter, it was held, put an end to the contract. At page 512 of the opinion the court cites cases which indicate the universality of the rule.

One of such cases cited is **The Frankmere** (262 Fed. 819). That case involved the requisitioning by the British Government of a ship under charter. In reaching its conclusion the court stated:

" . . . the contract was thereby frustrated when the government took possession of the ship, and the rights of the charterer were absolutely ended and terminated, and those of the owner, subject, however, to the paramount power of the government to use the ship without consulting the desire of the owner, revived, as though the charter had never been entered into."

In the **Omnia case, supra,** at p. 513 it was pointed out that "the effect of the requisition was to bring the contract to an end, not to keep it alive for the use of the Government." Continuing, the court significantly stated:

"The Government took over during the war railroads, steel mills, shipyards, telephone and telegraph lines, the capacity output of factories and other producing activities. If appellant's contention is sound, the Government thereby took and became liable to pay for an appalling number of existing contracts for future service or delivery, the performance of which its action made impossible. This is inadmissible. Frustration and appropriation are essentially different things."

Applying the principles so clearly expressed in the foregoing authorities to the situation herein, I am of opinion that the taking of the tugboat by the Government in the manner and under the circumstances above disclosed effectuated a frustration of the contract sued on herein.

Jurisdiction of Public Vessels Act—Negligence of Crew

In **Roah Hook Brick Co. vs. Erie Railroad Company,** U. S. Dist. Court, Eastern Dist. of New York, (1945 A. M. C. 1197) the owners of the scow Roah Hook allege in a libel that their scow was delivered to the respondent and upon redelivery was badly damaged. Respondent seeks to implead the United States in this action, which arises upon the exceptions filed by the United States. Further allegations show that, pursuant to instructions from agents of respondent United States, the scow was delivered alongside the SS Will Rogers at a pier in North River, New York. At the time of the arrival of the scow, the only berth available was at the end of the pier. Libelant claims that the scow was exclusively in the custody of and under the control of the personnel of the SS Will Rogers, which is a public vessel. The scow was shifted around and finally broke adrift, causing damage to certain other piers in North River. The exceptions of the United States are based upon the theory that the only possible statutory basis of jurisdiction is the Public Vessels Act of March 3, 1925. (c. 428, 43 Stat. 1112, 46, U. S. C., secs. 781-790). The United States maintains that the mere delivery of the scow in the vicinity of the berth at which the SS Will Rogers lay created no contractual obligation upon the part of respondent.

The Court agrees with this contention. However, it points out that the libel under attack affirmatively alleges negligence on the part of the personnel of the SS Will Rogers. This theory as advanced by the United States is one that has already been ruled upon by our courts, namely, **Canadian Aviator, Ltd. vs. U. S.,** (324 U. S. 215, 1945 A. M. C. 265), which was decided in February, 1945. The court holds that the Public Vessels Act permits the assertion of liability in admiralty against the United States **not only** where the vessel itself is the offending thing and physically caused the damage, but also where there has been negligence **on the part of a crew of a public vessel.** In that case the District Court was affirmed and the Circuit Court was reversed even though there was no physical contact between the vessels and the only basis for jurisdiction under the Public Vessels Act was the negligence of the crew. The Court was bound to take the allegations of negligence as true for the purpose of determining the exceptions. The exceptions of the United States were overruled.

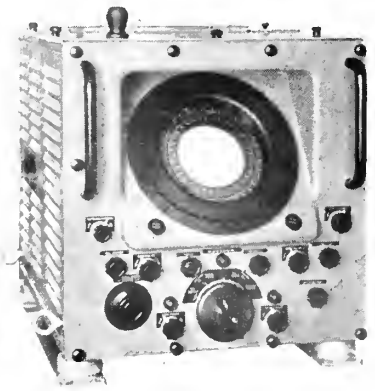
Radar As An Anti-Collision And Navigational Device

By Commander Oscar C. Rohnke
USCG

To the landlubber, the device pictured above may look like a weather - vane. However, the mariner knows that it represents a form of anti-collision and navigational radar designed to overcome the handicaps of low visibility, one of the deadliest and costliest perils of the sea since time immemoriol. Bethlehem Steel Company's New York shipyards have installed radar of this type on Liberty and Victory ships. Troopships so equipped will have a visibility range of fram 250 yards to 30 miles in the foulest of weather and darkest night. All above-water objects will be readily detected by this magical electronic "eye" even though the ship's log reads "visibility zero."

●

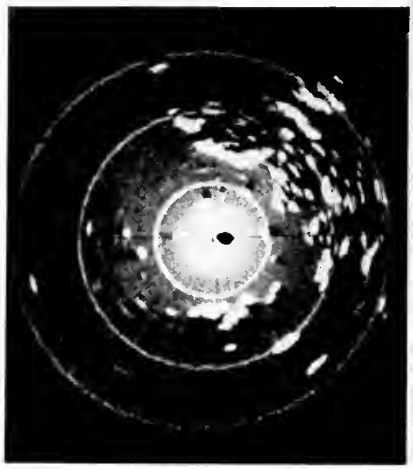
Radar direction finder manufactured for the Navy by the Submarine Signal Company.



Now that the veil of secrecy surrounding the development and use of radar has been lifted, much publicity is being given this instrument which played such a large part in winning the war. Most of the information made public, however, has dealt with the principles of radar with very little stress being placed on the operational aspects and benefits of the instrument.

The possibility of collision is one of the mariner's constant, most feared perils. It is a danger greatly increased during periods of low visibility, but it also is a peril greatly reduced by radar, which will give its operator range and bearing, I repeat, range and bearing, of an object regardless of visibility. Radar can see through fog, rain, snow, sleet, darkness and all forms of low or zero visibility. Heretofore during such periods the men on a vessel's bridge had to rely primarily on sound and the lookout's visibility for the detection of the presence of other objects in their immediate vicinity. Neither form of detection is too reliable in fog. They resulted in vessels groping their way at slow speed through low visibility areas with the danger of collision and stranding constantly present. Now this danger can be practically eliminated by the use of radar which, to put it plainly, indicates the presence of all above-water objects by reflected radio waves. These waves in turn are translated by the radar instrument into a picture form which appears on what is called "the scope."

Here is a good example of how radar can contribute to the safety of a ship already modernly equipped in the pre-radar sense of the word. Not many years ago a large passenger vessel, proceeding through a thick fog, was approaching a light vessel. Radio beacon contact had been established on the light ship by this passenger vessel. But even with the aid of the radio beacon, the exact position of the light ship was not known. Running down the radio bearing, the liner evidently intended just to clear the light ship, thereby establishing definitely the ship's position. But instead there was a collision and the light ship was cut in two, sinking with the attendant loss



Photograph of General Electric's "electronic navigator," operating on radar principle that played vital role in war, is shawn here as it would look to marine pilot peering into field of instrument to see what obstacles lie in path of ship. This new radar device is used when fog, darkness, storm or any other kind of overcast condition limits natural visibility, and it can reveal land masses, other ships, lighthouses and buoys as far away as 30 miles, distance depending on the size and shape of the object. Skilled operator can quickly determine what kind of obstacle is represented by spots in radar field.

(The author is in the Communications Division, United States Coast Guard. Text is from an address delivered on October 18, 1945, at the Nineteenth Annual Regional Meeting, The Propeller Club of the United States, and American Merchant Marine Conference (U. S. Coast Guard Merchant Marine Council Panel), held at the Waldorf-Astoria Hotel, New York, N. Y.)

of the lives of several of her crew. Had the liner been equipped with radar there would have been no collision, because the exact range and bearing of the light ship would have appeared on the radar scope. The radar presentation plus the radio bearing would have clarified the entire situation. The characteristic code of the radio beacon would have provided the identification.

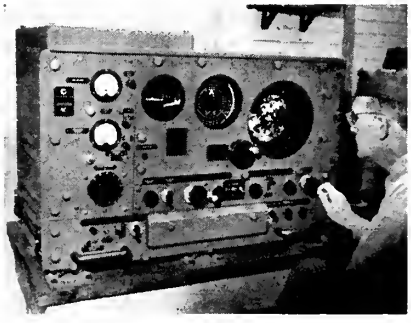
In northern waters the iceberg presents one of the navigator's greatest hazards, with the classic example of the Titantic remembered as the outstanding maritime tragedy caused by these floating ice mountains. But had the Titantic been radar equipped, she would have been cognizant of the presence of the berg which caused her death in time to avoid colliding with it. The bearing and distance of this berg, as well as of surrounding icebergs, would have been indicated as "pips" or objects on the radar scope.

An interesting speculation also can be made in considering radar in relation to the Titantic disaster. It is known that while the Titantic was sinking, another ship, the California, was nearby—so near, in fact, that her lights were visible. But because her radio officer had just gone off watch and communications were dead, the California steamed on entirely ignorant of what had happened to the Titantic. Of course, under present-day radio regulations, this situation would not occur.

However, for the sake of example, let us look at what we might have seen during those tragic minutes if it had been the day of radar. The California's radar screen would have shown relatively stationary "pips" indicating icebergs and another "pip" in motion, indicating a ship under way at good speed. The approaching "pip" blending with a stationary "pip" would have indicated a possible collision and this indication would have been more or less confirmed by the "pips" separating very slowly or not at all after their first meeting.

While on this part of my subject, I would like to repeat that icebergs can readily be seen on the radar scope. However, it must be remembered that for radar to pick up objects, they must be above water. Growlers, especially those just awash, may prove difficult for the instrument to pick up in a heavy sea. On the other hand, collision with such a growler would probably cause only slight damage.

Vessel collisions are not always the fault of low visibility. Sometimes they are due to personnel failures in which the human error in judging distances by means of the seaman's eye results in accident. It is difficult at times, and especially at night, to estimate distances. But radar does not make an estimate. Instead it indicates range and bearing with a high degree of accuracy. Thus it is reasonable to assume that personnel failures can be reduced through the use of radar.



Above is main Raytheon SG ship search radar. Operator is obtaining accurate range and bearing of target. Below is the "scope" of Raytheon SG radar, showing Cape Code, Mass.

Raytheon equipment is now being installed on harbor craft for the Army.

By careful observance of the radar scope, even the movement of an object or vessel can be noted, and by use of a plotting board the speed and exact course of other vessels can be determined. However, it is not believed generally that this latter step is necessary for ordinary shipboard navigation. The common method of determining whether vessels are on collision courses is for each to take a bearing and then determine whether that bearing remains constant or changes. If it changes the vessels will cross clear, whereas a constant bearing means that the vessels are on collision courses. But when a "pip" or vessel appears on the radar scope, its movement or bearing can be noted and attentiveness to the scope soon will reveal whether the vessels will pass clear or whether a collision course exists and a change is necessary.

Safe navigation, of course, is of paramount interest to followers of the sea. Strandings, collisions and other accidents cost lives, time and money. Our shores are littered with the skeletons of vessels lost when their operators thought themselves in safe waters, only to be brought up suddenly hard and fast aground. Strandings occur in periods of both good and low visibility, but the latter produces by far the greater hazard. However, commercial shipping must meet its schedules, perishable cargo must be rushed to its destination. Every delay in entering or leaving a port is costly to the operators. As a consequence ship operators oftentimes take chances by running at excessive speeds in a low visibility area at a time when any movement of vessels opens the way to collision or strandings. Even on errands of mercy, rescue vessels, if they ran through periods of low visibility, endangered others as well as themselves.

Down through the years many devices have been added to ships'

equipment to aid in their safe navigation. These include the fathometer, the direction finder, the gyro compass, the patent log, etc. But now we have a new device that actually sees during periods of low visibility. Perhaps another example or two can help illustrate the real importance of radar.

Typical of American radar equipment which smashed both German and Japanese armed might in the conflict begun just four years ago is this lightweight, portable unit developed by the Westinghouse Electric Corporation for the U. S. Marine Corps. Silhouetted against the sky is the unit's rotating "beach umbrella" antenna used as a reflector in sending out shortwave radio pulses and as a receiver to "catch" wave echoes reflected by enemy targets. Designed for beachhead use, the complete unit weighs only 400 pounds, can be dismantled and packed in four 100-pound cases, and has a range of 80 miles.

●

P. G. Caldwell of General Electric exhibits an enlarged photo (labeled for identification purposes) taken of the viewing screen of the G.E. "electronic navigator," a commercial radar set installed on the American Mariner, a training ship of the U. S. Maritime Service, as it anchored one night off Niantic Bay in Long Island Sound. The G.E. radar set has been used recently by the ship in navigating Long Island Sound. It can detect through darkness, fog and storm the position of any above-water obstacles, such as lighthouses, buoys, icebergs, other ships and land, at distances up to 30 miles—depending upon the size and shape of the object. As a result of the successful operation of the unit aboard the American Mariner, General Electric has received an order to build additional units for installation on passenger ships now being built for the Maritime Commission.

Another example of a grounding that would probably not have happened had radar been available occurred in a harbor on the southern coast of Puerto Rico. This mishap took place because one of the navigational lights was out, and as a result a wrong turn was made. Again a radar picture would have indicated the position of the ship and no guesswork navigation would have been necessary. It might be added, too, that just a few months before this accident a tanker went aground in this same harbor and the master said the accident occurred because his charts were not up to date and he made a wrong turn.

Here again we have a personnel failure probably caused by a desire to meet the schedule assigned the ship. But once again radar undoubtedly would have prevented the accident by showing the master just where he was in relation to the beach.

Grounding in a fog is a somewhat different matter because, even though all precautions are taken, accidents still will happen. Currents, wind, sea, compass errors or lack of sights for days on end often place a vessel in a position entirely different than where she is thought to be. Even though radio beacons are available and soundings are taken, still they do not show a picture of the coastline.

There is the fairly recent example of the Henry Burgh aground on the Farallon Islands outside San Francisco with the lives of all aboard endangered and with the ship finally broken up, a total loss of ship and cargo. When she went aground a thick fog prevailed and a fairly heavy sea was running. The radio direction finder had been used but it was not properly calibrated. The fathometer was not used. The ship also was proceeding at a higher rate of speed than was prudent in making a landfall under the prevailing weather conditions. But in spite of all this, it is believed radar would have saved the ship because the instrument's picture would have outlined the islands, giving the bearing and distance offshore and showing a complete picture of the immediate surroundings.

It is difficult to conceive how a ship's officer could run his vessel aground if he intelligently compares

The German battleship Scharnhorst was hit by the second salvo at a 15-mile range with visibility of half a mile. For this miracle of range finding, even that early in the war, we have to thank radar. Five thousand ships of the Royal Navy have radar installations.

what is portrayed on the radar scope with the harbor chart.

I have given you, I hope, some idea of the tremendous contribution radar can make not only to safety at sea but also to the operating efficiency of vessels. To sum up, let me say that the distinct operational advantages of radar are:

(1) It is the best anti-collision device yet perfected.

(2) It makes for greater safety while piloting or making landfalls during periods of low visibility.

(3) It indicates continuous instantaneous accurate ranges and bearings of objects.

(4) It presents a chart-like picture of the surroundings, the presentation being in the nature of a polar chart.

(5) By observation of the scope movements of objects are indicated.

Some Disadvantages

(1) Objects cannot be readily identified. All objects of about the same size present the same size pip. However, identification can be made quite often by implication such as movement, relation to other objects, shape (used in landfalls), and sometimes initial range of detection (the latter giving an indication of the size of the object detected).

(2) Radar chart presentation on the scope requires interpretation due to line of sight characteristics which give shadow effects. In other words, larger intervening objects may blank out objects behind them.

(3) It can only be used for slightly over line of sight distance.

(4) Weather and sea return affect the picture.

(5) Objects sometimes not detected because of the movement of these objects caused by bobbing up and down in a seaway. Small vessels and buoys are particularly affected. The outgoing signals miss striking the object when it is in the trough of a wave, therefore there is no reflected wave for presentation on the scope.

(6) Non - conductors, such as wooden vessels, may give poor echo.

Coast Guard Releases Minimum Specifications for Radar Equipment for Maritime Use

The Coast Guard has released a set of recommended minimum specifications for radar for use aboard merchant ships as a result of studies made by the Coast Guard and recommendations offered by radar manufacturers and representatives of the maritime industry, which has worked in close cooperation with the Coast Guard.

The Coast Guard, by reason of its close association with the Maritime Industry in safety at sea problems, assumed the responsibility to determine the minimum specifications for radar equipment in an effort to provide simplicity of operation with optimum performance. The problem was quite extensive in its scope because of the varying operational requirements of the ship operators and the expense involved. The lifting of wartime secrecy on radar found the maritime industry limited in its knowledge of electronic navigational aids. The specifications will act as a voluntary guide for manufacturers of radar equipment and shipowners to formulate future considerations for the installation of radar equipment on all merchant marine vessels.

The first specification requires a three centimeter surface search radar primarily designed for ocean-going vessels to provide early warning of approaching vessels and navigational dangers on the open seas, as well as high resolution for navigation in restricted waters.

The second specification includes a three or ten centimeter surface search radar primarily designed for ocean-going vessels to provide early warning of approaching vessels and navigational dangers on the open sea as well as fair resolution for navigation in restricted waters.

The third specification sets forth a surface search radar primarily designed as an anti-collision device with a limited value for navigational purposes. In a letter directed to radar manufacturers, the Coast Guard said:

"These specifications have been prepared with full consideration given to the discussions presented at the meetings of radar manufacturers at Coast Guard Headquarters, Washington, and have been made as broad as possible without jeopardizing the safety value of the radar. While these specifications may seem unnecessarily explicit, many items have been included because of the lack of any performance standards in radar. As radar is a new art, and consequently is in a continual state of progressive development and improvement, these specifications are intended merely as a mutual voluntary starting point in the interest of standardization and adaptability to navigational aids."

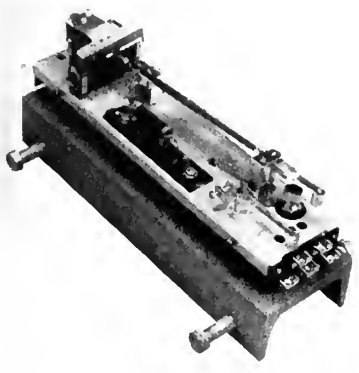
(Editor's Note: These specifications are available in our office, or can be obtained from Public Information Division, U. S. Coast Guard, Washington 25, D. C.)

Dry Storage For U. S. Navy

By David M. Ludlum

Naval scientists have turned up with a new one. Now it is dynamic dehumidification, or dry storage to the layman—a process of preservation which will keep Uncle Sam's veteran warships in fighting trim during these uncertain post-war years.

The problem of combating corrosion has faced naval men ever since man turned to iron and steel for marine construction. The time-honored method of storing a ship, employed after World War I, entailed covering all exposed parts of machinery and fittings with a thick coat of grease—



Humidity detective

a costly and laborious job—and it took several months to remove the grease, clean the machinery, and ready the ship for sea. The time lost in 1941 in preparing our 50 over-age four stackers for the British Navy was almost fatal and impressed naval authorities with the urgency of finding a solution.

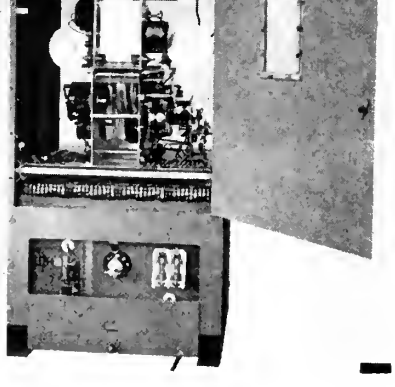
The U. S. S. Brooklyn was recently put in the Philadelphia Navy Yard for the dehumidification process. Others will follow soon. Eventually, there will be over 1000 ships of all types equipped with special air-conditioning apparatus and controls to maintain "little Sahara" climates in their holds. Officials estimate that with the aid of dehumidification it will be only a matter of days instead of months to remove these ships from dry storage berths and put to sea.

Dynamic dehumidification means lowering the moisture content of enclosed air to a desired level and keeping it there by inducing additional dry air when necessary. In the same manner as the ancient Egyptians sealed up their tombs, a ship is made air-tight; all vents, portholes, entrances, and hatches are hermetically sealed. Then dry air is pumped down the fire mains until temperature and humidity conditions reach a predetermined level. Air-tight sealing, of course, must be 100 per cent effective, so an ingenious "humidity detective" has been developed by naval engineers in conjunction with technicians of the Friez Instrument Division of the Bendix Aviation Corporation.

The humidity detective is the heart of the dehumidification process. It consists of 100 human hairs—preferably blonde, female locks which have not had a permanent wave; these are stretched between two sensitive holders. An increase of moisture expands the suspended hairs, while a decrease will cause a contraction. This slight movement is transmitted to a set of controls which sets in motion air-conditioning apparatus. Formerly, hair hygrometers were inaccurate at low humidity readings, but this has been overcome by lessening the pressure on the hairs and requiring them to do no work; the levers are actuated electrically.

Experiments have shown that humidities between 25 and 35 per cent will prevent corrosion of metal parts, yet will not cause damage to woodwork by excessive drying out. When moisture conditions vary from the set limits, air pumps are automatically set to work to return the humidity to the 25-35 per cent area. Temperature conditions, too, are regulated by this device, whose preliminary trade name is "temperature-humidity register-controller."

Front view of open temperature-humidity register controller.



Dry storage is a time-saver to install and a labor-saver to operate. It will take far less time to set up the temperature-humidity register-controller with the attendant air-conditioning apparatus than the old grease coating method formerly employed. Thus, ships will be in and out of storage in short order. They can be readied for sea or put in storage as the world political and military situation varies.

Furthermore, it will be a great labor-saver to the Navy, already hard-pressed for experienced hands. No longer will large crews of watchmen and maintenance men be necessary on every laid-up ship. As a check on the humidity detective, the engineer's control room will be equipped with a ticker tape register which will stamp at frequent intervals the temperature and humidity from numerous locations throughout the ship. In addition, the device contains an automatic calculator which adds and averages all the humidities throughout the ship. Thus the chief engineer can sit at his desk and have an up-to-the-minute over-all picture of air conditions on his vessel. All laborious psychrometer swinging will be eliminated, and the number of watchmen needed greatly reduced.

The Navy is also experimenting with static dehumidification. This form of dry storage consists in putting desiccant material into a single hold or room and then sealing up all outlets. The desiccant then absorbs moisture from the enclosed air and maintains a low humidity level indefinitely. The quality of the air can be checked by dials which register inside conditions by remote control. This method is looked on with favor by the United States Army; it plans to package individual guns and tanks by boxing them in metal containers to prevent rust and corrosion. Although satisfactory on small units, this small-scale air-conditioning process is not suitable for larger units such as ships.

U. S. Coast Guard Cutter Mendota (Owasco Class).

Turbine-Electric Coast Guard Cutters

By J. A. Wasmund

The completion of the 4000-shp, single screw, turbine-electric cutters of the Owasco Class will give the United States Coast Guard a total of 13 sister ships embodying the most advanced engineering thinking on turbine-electric alternating-current propulsion. Eleven of these cutters were contracted for at the Western Pipe and Steel yards, San Pedro, California, and two more at the Coast Guard Yard, Curtis Bay, Maryland. Several of the San Pedro cutters have been completed, and the balance are in various stages of construction. These ships, with the exception of a few small items, are completely Westinghouse equipped and are the first turbine-electric alternating-current vessels to have complete automatic control from the pilot house. They are also provided with either automatic or manual control from the engine room. Propulsion motors and generators are of minimum size because the use of regulated stability and automatic synchronizing permits the machines to be designed with very little inherent torque margin. Most of the vital propulsion auxiliaries are driven by motors taking power from a transformer connected to the propulsion bus and, therefore, operate at varying frequency and speed. Maximum economy is obtained at the steam rate of the propulsion turbine.

Each ship is equipped with one propulsion generator, which supplies power to one synchronous propulsion motor. Speed control of the motor is obtained by adjusting the speed of the turbine driving the propulsion generator.

(The author is a marine engineer with Westinghouse Electric Corporation, East Pittsburgh, Pa.)

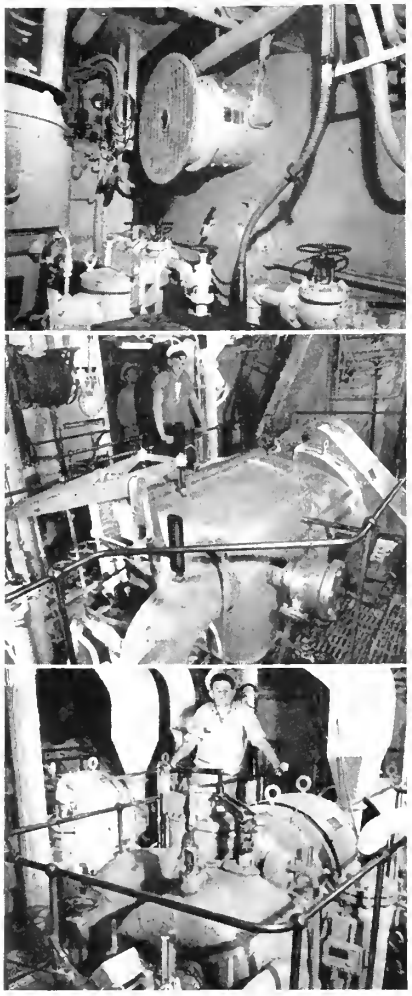
Propulsion Turbine

The propulsion turbine is of the single-flow complete-expansion, combined impulse and reaction type directly connected to the generator by means of a flanged coupling.

Steam at 600 psi, 750° F. total temperature is admitted to the chest through an oil actuated manually controlled throttle valve and the exhaust vapor is discharged downward into a surface condenser mounted below the turbine and bolted directly to the exhaust flange.

The entire turbine is supported at four points; one on the forward end, one on each side of the exhaust end, and one on the horizontal centerline at the exhaust.

The support on the centerline at the exhaust end is anchored solidly to the foundation, and the two on the side of the exhaust are supported by



Top: Forward end propulsion motor.

Center: Main propulsion turbine generator set.

Bottom: Auxiliary turbine generator sets.

flexible beams which permit transverse expansion of the unit. The high-pressure end of the cylinder base is supported on a short I-beam section placed in a transverse direction. The web of this I-beam furnishes the necessary flexibility to allow for any longitudinal movement due to expansion and contraction of the cylinder.

The turbine "brain" or governor consists of essentially three parts: a fly-ball mechanism, which responds to changes in speed; a governing oil valve, which transforms the changes in force from the fly-ball into oil pressures acting on the control relay; and a hydraulically operated mechanism for actuating the steam valves.

Speed of the turbine is controlled by altering the setting of the governor through the speed changer mechanism, which is connected to

Plans of this vessel will be published in the February issue.

the engine room control cubicle and actuated by remote control from the bridge or from the engine room by automatic or manual means.

In order to obtain a satisfactory heat balance for the equipment, the propulsion turbine is provided with an opening through which steam may be extracted for feed heating when there is not enough auxiliary exhaust for the purpose, or through which steam can be taken into the turbine from the auxiliary line when there is more auxiliary exhaust than is needed for heating purposes.

The main condenser is located beneath the propulsion turbine unit. The condenser is bolted directly to the turbine exhaust flange and is supported by the turbine foundation structure. The condenser is of the "radial flow" type, which provides steam access to the entire circumference of the tube bank.

Circulating water is supplied by scoop injection and in part by the main circulating pump, which is in operation at all times but performs its principal service during standby periods and when running astern.

Generator

The propulsion generator is rated 3200 kw, 3 phase, unity power factor and is capable of supplying full power to the propulsion motor as well as approximately 100 kw to the variable frequency auxiliary bus at the same time. The generator is direct connected to the turbine shaft and has a rated speed of 5400 rpm, supplying 2400 volts at 90 cycles when running at this speed.

The generator is of the completely enclosed type; an air cooler is located beneath the generator; and all of the ventilating air is passed through the cooler before it is recirculated through the machine by shaft mounted fans on either end of the rotor. By this means the generator is assured of a continuous supply of cool, clean air which cannot become contaminated by foreign matter. The collector is located outside of the air housing, thus preventing the circulation of brush dust which would tend to clog the ventilating spaces and reduce the creepage insulation. An unusual feature is that the cooling medium is fresh water condensate instead of sea water.

Temperature detectors embedded in the stator winding of the generator are connected to a bridge type indicating meter on the control board. A multi-pole switch permits the operator to observe the temperature at two points in each phase of the winding. An unusual rise in temperature is, of course, a warning of impending trouble. In addition, a temperature relay indicates by audible and visual alarm any overheating of the generator winding.

Strip type space heaters are located inside the cover at the bottom of the frame. These heaters are energized manually whenever the machine is out of service for more than a few hours, their purpose being to keep the internal temperature a few degrees above atmospheric, thus preventing condensation of moisture inside the enclosure.

Propulsion Motor

The propulsion motor is rated 4000 shp when running at 180 rpm, which corresponds to 5400 rpm of the turbine-generator set. It is of the synchronous type with heavy pole-face damper windings for maneuvering and is provided with two bracket type tapered roller bearings which make the motor unusually short and insure very low "break-away" torque.

The motor is of a semi-enclosed type and is waterproof in the lower portion up to the bearing seals on the shaft. Being in a separate motor room, it was not considered necessary to provide a completely enclosed machine. Motor driven, axial flow fans mounted on the upper part of each endbell take ventilating air from the motor room and force it through the motor winding. The heated air is passed through coolers mounted on the upper part of the motor frame and the cooler air discharged to the motor room for recirculation.

Temperature detectors, alarms and space heaters are supplied as described for the propulsion generator.

The purpose of the propulsion control is to regulate the flow of energy from the turbine through the generator to the motor. Since both the motor and generator are synchronous, speed variation is accomplished by varying the speed of the turbine-generator set. Direction of propeller rotation is reversed by interchanging

the connection of two of the three leads between the motor and the generator.

For normal running operation, the motor and generator field circuits are connected in series across a common exciter. During starting the motor operates on the heavy pole-face damper winding as a squirrel-cage induction motor with its field circuit short-circuited through a starting resistance. At the same time the generator is heavily over-excited in order to prevent collapse of the generator voltage and to provide high synchronizing torque.

The propulsion control is designed to perform the following functions:

(1) Start, stop, reverse and control the speed of the propulsion motor from the bridge or engine room.

(2) Provide automatic synchronizing which takes into account slip frequency of the propulsion motor.

(3) Provide automatic stability control over the entire speed range except during the synchronizing period.

(4) Maintain a generator field of not less than 60 per cent of the off position, so that sufficient excitation for driving the auxiliary motors will be maintained when the propulsion controller is in the stop position.

(5) Provide for communication from pilot house to engine room by means of an engine order telegraph whenever control is delegated to the engine room.

The above list of control functions is indeed remarkable when it is remembered that this is the first alternating-current turbine-electric vessel to be provided with anything except manual engine room control. By means of a single lever, located on the pilot house control stand, the operator has full control in ahead and astern directions. A movement to the first point in either direction will synchronize the propelling motor and rotate it at minimum speed. Additional movement of the same lever will bring the motor up to the selected speed.

In order to utilize the better fuel economy provided by the main turbine, provision is made to drive the boiler feed pump, forced draft fan, main circulating pump and propulsion motor ventilating fans from a variable frequency bus energized through a 125 kva, 2400/600 volt air cooled transformer. The transformer is designed to operate satisfactorily over a frequency range from 90 cycles to 15 cycles. Three high voltage fuses are mounted in a compartment adjacent to the transformer.

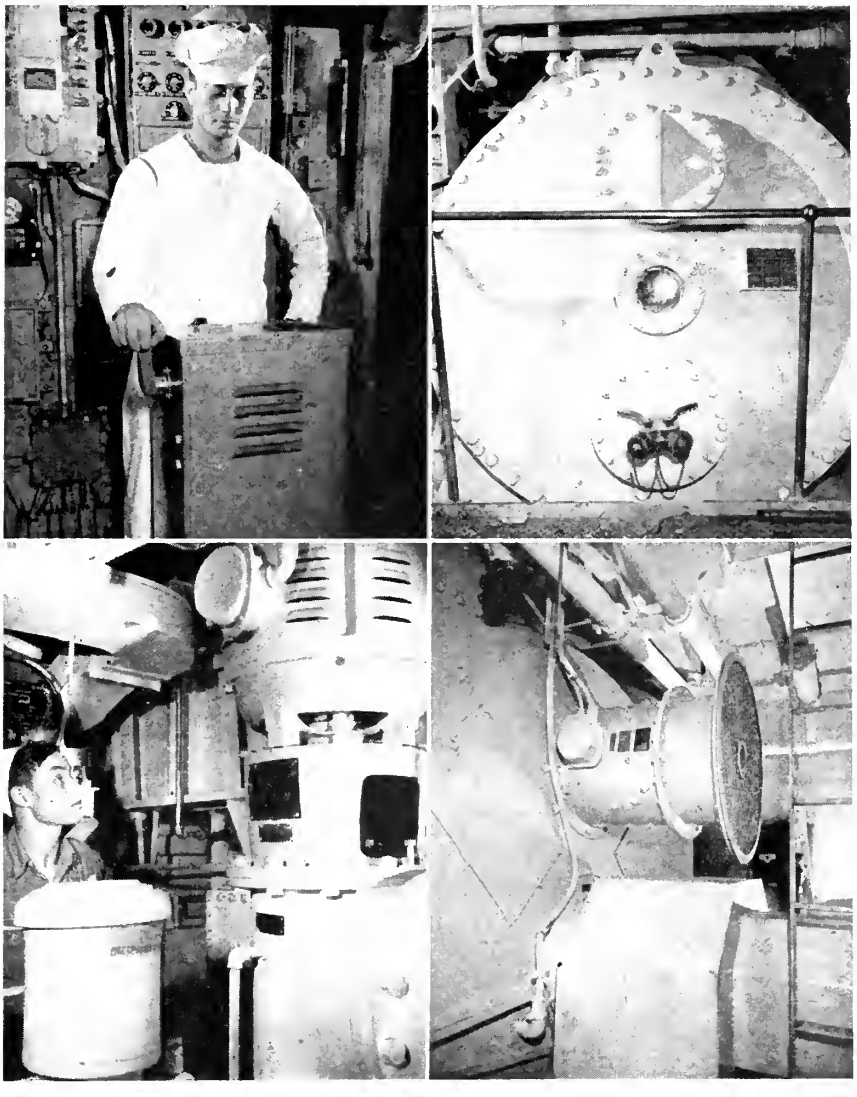
Bus transfer equipment is provided on the auxiliary switchboard for the purpose of transferring the variable frequency auxiliary bus feeders from the transformer secondary bus to a constant frequency 60-cycle, 450-volt ship's service bus. Transfer can be made manually, but is normally accomplished automatically by a relay which operates when the transformer voltage drops below a predetermined value. From experience it appears that transfer will not often be required.

Satisfactory operation can be obtained on the constant frequency bus up to two-thirds propeller speed, which corresponds to 60 cycles on the propulsion bus. Beyond this point transfer must be made to the variable frequency bus in order to obtain sufficient speed from the auxiliary motors.

Two identical ship's service turbine-generator sets are located on the port side of the engine room adjacent to the propulsion turbine-generator set. Each set consists of a high speed non-condensing turbine arranged to drive, through the medium of a reduction gear, a 219 kva, 80 per cent power factor, 450-volt, 60-cycle, 1800 rpm alternating current generator; a variable voltage propulsion motor and generator exciter having a normal rating of 56 kw, 250 volts with a special maneuvering capacity of 750 amperes at 275 volts; a constant potential 30 kw, 125 volts ship's service d.c. generator; and a 3 kw, 125 volt exciter for the 219 kva a.c. generator.

Two generator and distribution switchboards are divided by the propulsion control board, and all three are located fore and aft on the starboard side of the engine room. The automatic combustion control board

Upper left: Pilot house control stand. Upper right: Main condenser. Lower left: Circulating pump for main condenser. Lower right: After end of propulsion motor.



Propulsion control and auxiliary switchboard.

for the boilers is also in line with and at the forward end of the electrical switchboard.

There will, of course, be many applications where automatic control cannot be justified because of first cost, lack of trained personnel for maintenance purposes, or simply because such refinement does not fit in with the performance expected of the vessel. However, to any operator familiar with manual operation the rapidity with which reversals can be made without abuse to motor and generator due to synchronizing at the optimum moment will seem almost unbelievable.

In the automotive world, hydromatic transmission probably never will replace the gear shift lever on a tractor; it does seem a safe assumption, however, that most post-war automobiles will introduce a refinement of that sort. Similarly, it is to be expected that automatic synchronizing will find an important place in alternating-current electric ship propulsion.

Industrial Cooperation Shapes Character of New World Market

By R. D. McManigal
Vice President,
Westinghouse Electric International Company.

R. D. McManigal

Looking toward the markets of the Pacific and those of Central and South America, one important concept can be used in estimating the extent of future trade. This is the idea of national industrialization which has taken hold in these areas as firmly as it gripped this country during the latter half of the 19th century. Westinghouse and many other concerns interested in these markets are planning to establish representation on the West Coast which will become increasingly more important as a center for closer contact with these sectors.

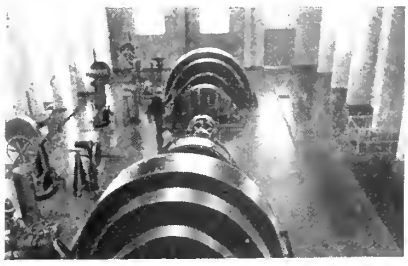
Because of conditions caused by war, task forces of American merchant vessels will carry materials for immediate rehabilitation to all corners of the world, but part of their cargo will consist of equipment destined to assist in shaping a new and permanent industrial economy. And there will also be an invisible cargo—our technical skill—one of the most important commodities we have for export, which will materially aid the growth of foreign trade.

For many years, Westinghouse has been conscious of the need for greater world-wide industrialization as an answer to many regional economic problems, and has recognized that this industrialization cannot be brought about purely with machinery. Accordingly, a policy has been adopted of exporting technical "know-how" through a series of technical assistance agreements with established or new electrical manufacturers in many parts of the world.

These agreements involve not only the delivery of engineering drawings, calculations and designs to associates abroad but also provide for the training of key operating personnel in the factories of Westinghouse to permit them to carry to their plants the most modern and efficient manufacturing methods. The success of this plan has more than attested to its correctness, and it is intended to continue this type of aid in addition to more direct help to broaden the scope and meaning of foreign trade.

In the Far East there is the great potential market of China, where an ancient nation is planning to rebuild on a new footing, relegating the agrarian nature of its former economy to a secondary position. Adequate sources of cheap power will be developed. Modern equipment for manufacturing industries will be supplied to replace and augment existing facilities, a large part of which has been broken into small units and thrust far into the interior under a policy of military dispersal. Development of electric power plants, and adequate transportation systems, machines and machine tools, will be the keys that unlock the rich natural resources of this country, convert them into useful products and help elevate living standards of a primitive people.

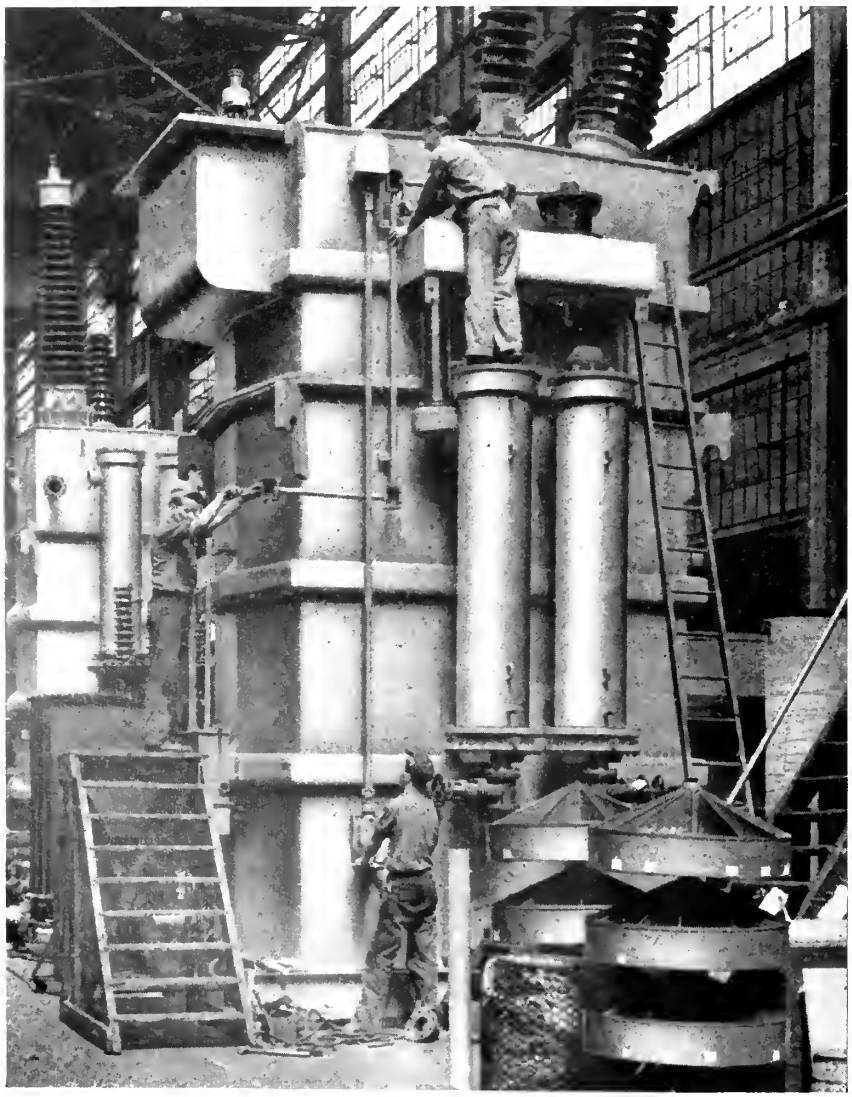
Also in the Far East are the Philippines and the Netherlands East In-



CHILE (Above): Two 10,000 kva, 3 phase, 50 cycle, 6600 volt, 300 rpm Westinghouse horizontal waterwheel generators, driven by double overhung Pelton impulse turbines installed in the Los Quilos plant of Fabrico de Cemento, El Melon. Power is transmitted at 66 K.V. to Chile's largest cement production plant at La Calera, 55 miles away.

MEXICO (Left): First of three 31,000 kva, 600 rpm vertical Westinghouse waterwheel generators driven by Baldwin-Southwark reaction type turbines supplied to Comision Federal de Electricided for the Ixtapantongo plant, located approximately 50 miles from Mexico City.

URUGUAY—One of the thirteen 11,000 kva, single phase, oil insulated, forced circulation, water cooled Westinghouse power transformers supplied to Comision Technica y Financiera de los Obros Hydroelectricos del Rio Negro, to step up the generating voltage of their 128,000 kva station at Rincon del Bonete to 161 kv for transmission to Montevideo, where 13 similar Westinghouse transformers step the voltage down to 34.5 kv for primary distribution.



dies, which also will need help of a similar nature if not as great in scope. Combined with other markets of the world this presents the greatest job ever handed to the ingenuity and productive genius of the United States.

While this policy of industrial cooperation and over-all planning is essentially different from the normal, superficial understanding of foreign trade, the need for operations of this type has long been realized by many American businessmen. Even the general public, long separated from actual facts about foreign trade, is taking new interest in this form of international cooperation because it is grasping the meaning of its importance in stimulating world commerce, knowing that the latter has an important relation to its own economy.

Generally exploded is the myth of this country's self-sufficiency, which was based on the statistics that we consume 90 to 93 per cent of our own production. These statistics were proved to be deceptive during the war when the public was made aware of the critical rubber shortage; when we began to scrape bottom on tin deposits; when the daily living of everyone was affected in some manner by the shutting off of world markets. More general thought was given to foreign trade, and even our own industrialization was traced to a background of international trading. Other facts became obvious about the 7 to 10 per cent of our goods which we exported. Industries employing thousands of workers were almost entirely dependent on foreign trade for existence. Foreign buyers were taking from 60 to 65 per cent of our raw cotton, 22 to 41 per cent of our leaf tobacco, and a great percentage of our electrical machinery.

Two-way trade is considered the answer to greater foreign trade, and two-way trade can find no more logical source than in mutual assistance to help countries of the world get on their feet and begin producing. In line with this thinking, Westinghouse is pioneering with the establishment of an Import Department. This department is being organized as an exclusive distributor in the United States for a number of foreign sources of supply. Its program calls for a "long-pull" development and relationship with foreign manufacturers, to which Westinghouse brings an intelligent knowledge of American markets and ample financial resources to handle distribution backed up by energetic salesmanship. This development of "the other street" in foreign trading is a realistic approach in helping to shape the character of the new market.

In the markets of Central and South America Westinghouse will continue to be active in extending technical help and equipment in the establishing of a greater industrial capacity. In Brazil Westinghouse has

Pacific WORLD TRADE

What Will the Industrialization Of Asia Mean for America?

By *Dr. Eugene Staley*

Dr. Staley is Director of the Institute of Pacific Relations for the San Francisco Bay Region, and, as announced elsewhere in this issue, will instruct a class in world trade in the Stanford Graduate School of Business. In a recent address before the Foreign Trade Association of the San Francisco Junior Chamber of Commerce, he made a most comprehensive analysis of potential trade with Asia. He has revised and supplemented it for this publication.—Ed.

Dr. Eugene Staley

Across the Pacific Ocean to the west there are 1.2 billions of people. That is more than half of all mankind. In the Europe-centered world of the past, these people have counted for relatively little in world politics and world commerce. In the future they are going to count for much more.

Yet, if you talk with their leaders you get the very strong impression that they are going to modernize, that they are going to adopt modern industry, and that quite soon. What will Asiatic industrial development mean to American foreign trade, labor standards, and living standards?

Where can the United States look more appropriately than here to the West Coast for intelligent, well-considered judgments on these problems, and for constructive leadership in transpacific relationships?

Let me turn now to the question, "Is Asia **going** to industrialize?" There are a number of reasons for answering "Yes." One is the intensity of determination on the part of the peoples of Asia, or at least their leaders and those of them who are politically conscious, for industrial development. There are two reasons for that.

First, they want to raise their living standards, and they know as well as we do that the only way to be able to consume more year after year is to produce more. We can best help other peoples to raise their living standards, not by giving them charity—though gifts are necessary for a time, to meet relief and rehabilitation problems in the wake of war—but by helping them to produce more efficiently. That means equipment and know-how. Production is the key to higher living standards, and the peoples of Asia are, at least through their politically conscious leaders, very much set on getting higher living standards through improved capacity to produce.

Secondly, they realize that ability to resist aggression and to swing some weight in the politics of the world depends on military power. An essential basis of modern military power is industrial capacity. That is another reason why the peoples of Asia are interested in industrial development.

In China, a large-scale plan for railroads and ports, factories and improved agriculture was put forward right after the first world war by Sun Yat-sen, the founder of the Chinese Republic. It received little attention at the time, but in recent years the government of Chiang Kai-shek has come forward with a modernized and extended version setting very ambitious goals twenty or more years ahead. Minister Wong Wen-hao, an eminent Chinese geologist who is Minister of Economic Affairs and now Vice-Premier, has called for a total gross investment in Chinese development of the equivalent of ten billion dollars over the next four to five years, the funds to come partly from domestic savings and partly from abroad. One-third would be devoted to improvement of transportation, one-third to industry, and one-third to agriculture. The Chinese government is now seeking equipment and technical aid with which to embark on many concrete development projects scheduled for the next year and the next three years.

You have probably heard of the famous Bombay plan for rapid economic development on India put forward by a group of Indian industrialists. The avowed aim is to double the per capita income of the people of India in fifteen years. Other plans, some evidently designed to outbid the Bombay plan, have come from other groups in India. The government has been impelled to put forward projects of its own.

Soviet Asia, under successive five-year plans, has already made remarkable development, and will make more.

So, all through Asia there are hopes and ambitions and very intense

desires for industrial modernization. That is the first reason why I would answer "Yes" to the question, "Is Asia going to industrialize?" There is a more intense desire than there has ever been before, and the will to do it.

A second reason for answering "Yes" is that the requisites of modern industry are at least potentially present in Asia. These might be classified under four headings: men, materials, money, and markets.

The first of these—men—is the most fundamental. Modern industry depends on trained man power. Can the Chinese, for example, handle modern techniques and run modern production enterprises? I think the answer is clearly "Yes." The Japanese learned how. Chinese students in this country have made excellent records in many fields, including sciences, engineering and economics. Last year in Kweiyang I met a man named Wang, who was the manager of a truck maintenance shop. He was trying hard to keep trucks operating on the road from Kunming, where military supplies were landed by air, to Chungking and forward bases. He had terrific problems. I saw men making bolts by hand: heating an iron rod and shaping the head with a hammer, putting it in a vise, and then using one of those hand-threading devices to cut the threads. They made the nuts in the same laborious way. There were many other handicaps from lack of modern equipment and materials. Mr. Wang, who was thoroughly alive to all of these problems, was doing the best he could. An American lend-lease man who had formerly worked for Standard Oil of New Jersey was stationed there, trying to help the Chinese in their truck maintenance problems. He told me that he would be willing to put this man Wang up against any American that he had known in similar kinds of work, so far as general competence and efficiency were concerned. Where Chinese have had a chance to learn modern technology, they have produced excellent men. I am thinking of persons I know in such fields as public health, and in economic research, which is my own field. There is no lack of capacity in the men of Asia. There is no color line in ability to do a good job with modern techniques.

Materials. Some of the earlier views about the natural endowments of China and of other Asiatic countries may have been on the optimistic side. But these countries do have enough resources of the right kinds to give them a solid basis for at least a very considerable industrial development. This rather dogmatic statement will have to suffice, for amplification of it would carry us into too much detail.

Money. The less-developed countries of Asia certainly lack a large flow of savings which can be tapped for capital investment. They would like very much to have loans from countries with more savings. That would make their task of modernization much more rapid and less painful. But even without loans from abroad, as peoples have learned from the example of the Soviet Union, it is possible to build transport lines and factories by squeezing the capital out of the standard of living of the people and by deliberately holding consumption down in order to "plow back" the first results of improved productive power in the form of still more industrial equipment. This process would necessitate tremendous human suffering if industrial development had to be financed that way in the countries of Asia, and it could only be done by totalitarian regimentation. Still, it could be done. I am convinced that it would be done, in view of the tremendous stake the people of Asia see in achieving rapid industrial development.

As for markets, the potential capacity of the peoples of Asia to afford goods that they now lack depends on their ability to produce and distribute. Certainly there is no lack of need. It is hardly necessary to dwell on that.

A third reason for thinking that the people of Asia are going to adopt modern production methods is that they now have several successful examples to follow. Only recently Japan and the Soviet Union have achieved very rapid industrial development. So I would answer "Yes" to the question, "Is Asia going to industrialize?"

But that doesn't answer the more difficult question: "When?" "How soon?" As you all know, that great Asiatic market, 450,000,000 Chinese customers, has been "just around the corner" for decades. It is still just around the corner. How long is it going to remain there?

Of course, any forecast on such a point is speculative. I think that the answer depends primarily on factors that, after you have analyzed them and summed them all up, could be labeled, broadly speaking, "political." In other words, the natural resources, the human capabilities, the markets, and the ability to get capital by domestic savings or foreign borrowing are potentially ready to jell into rapid industrial development in Asia, and especially in China. The two things that might stop that process or retard it are lack of internal unity, which would prevent the development of strong government capable of providing leadership, and serious world political complications, threatening a new outbreak of war. This latter might cut down the amount of technical aid and equipment which Asiatic countries could get from abroad, or it might conceivably have the opposite effect by leading one or more great powers to promote industrial development in Asiatic countries in the hope of building up military allies. You can speculate about these matters at leisure. But these are the real factors you have to weigh in deciding how soon industrial development is really going to take place on a considerable scale in Asia. Given internal and external security, Asia is on the verge of a very considerable advance.

Now, let's turn to the question, "What is industrial development in Asia going to mean to the United States?" First, let me dispose of three wrong ideas. One is that there is not enough work in the world to go around, and if the peoples of Asia acquire machines and learn how to work more efficiently, that will throw our people out of jobs, undercut our living and labor standards, and generally work havoc with our economic system. In order to see the fallacy of that rather crude conclusion, you simply have to look at the need for production in the world. There is little danger of producing too much for a long time to come. Of course, there is danger of getting an unbalance in production, by which too much of some things are produced and not enough of other things. But to produce too much of things in

Pacific WORLD TRADE

general is unthinkable for the near future.

There are five basic needs that the world's productive system should meet: food, clothing, shelter, health care, and education. How well are these needs being met?

Food. Sixty per cent of the world's gainfully occupied people are normally engaged in the production of food.

Clothing. If all people used as much cotton per person for apparel and household furnishing as was used before the war in the United States, cotton consumption would be three times its highest point in the past and textile output would have to be increased in proportion.

Shelter. Just look at the houses that people call home in China or the Philippines or any other Asiatic country, and it is obvious that the limit to useful house production is simply ability to produce more and hence to afford better accommodations. Today in California no one is likely to argue that the world has too much housing!

Health care. Soap we take for granted, yet it is a vital health commodity. For the people of the world in general to be able to use half as much soap per person as Americans now use, the soap output of the world would have to be more than doubled. Hospital beds are a rough index of availability of modern medical care. In the United States, where we think many rural areas are undersupplied, there were 11 hospital beds per thousand people before the war. In China, the average is something like 11 per 165 thousand, and the Chinese National Health Administration has an ambitious program for raising that to one hospital bed per five thousand people.

Education. A high level of popular education is impossible in a country living near the margin of subsistence. People must be able to spare the time of their children and to afford a fairly heavy investment in equipment and in the training and maintenance of teachers.

Past history does not lead us to expect that improved ability to produce will, after a time, lead Asia to stop buying or even to buy less. Quite the contrary. As the United States developed industrially, it bought more than the rest of the world rather than less, and sold more to the rest of the world, too. The

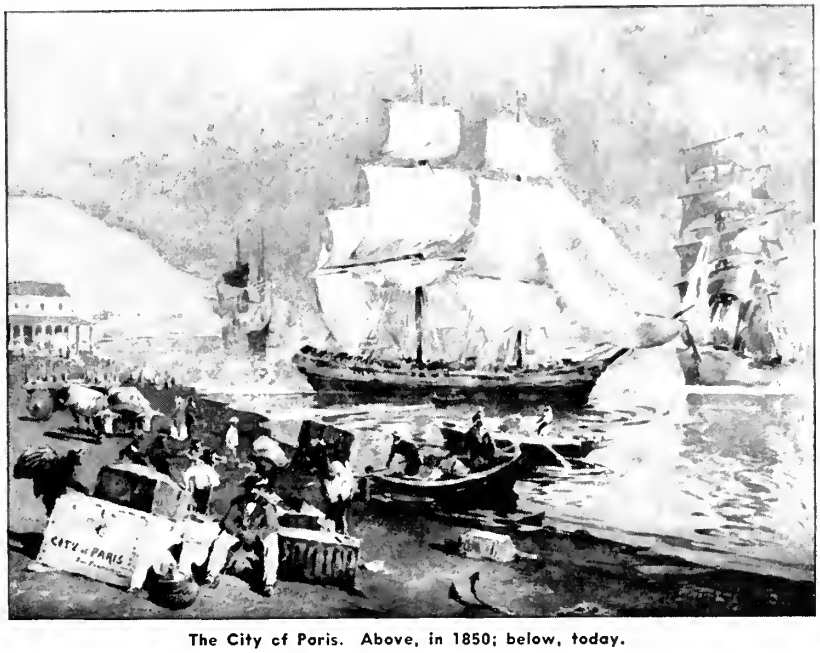
(Continued on page 50)

A Great Department Store Started on a Ship

In 1850 the Ville de Paris, a chartered ship of adventure, sailed into San Francisco Bay with a cargo of silks, laces, shawls, trinkets and wines, which were sold to the people on beaches from the decks of the ship by Felix Verdier.

San Francisco's City of Paris Department Store, operated by Paul Verdier, is an outgrowth of that early "steamer day."

Nearly every business establishment in any port city owes its origin or development, in some measure, to its shipping activities.



The City of Paris. Above, in 1850; below, today.

INDUSTRIALIZATION OF ASIA

(Continued from page 49)

same thing has happened in the case of most other countries that have undergone rapid industrial development, with some possible qualifications about Japan, and with the one exception of the Soviet Union, where there were special reasons related to military insecurity and divergence of systems that made the Soviet Union deliberately pursue a policy of self-sufficiency.

Look at the difference between Canada and Latin America as markets for American products. Canada has 12,000,000 people, Latin America has more than 120,000,000 — more than ten times as many. Yet Canada normally buys almost as much from the United States as does all of Latin America. The main reason is that Canada is a modernized, industrialized, highly productive country, with larger incomes per person, and therefore high purchasing power. As Latin America develops its productivity it, too, is likely to buy more, rather than less, if history is any guide.

The United States, and this applies to the West Coast of the United States in particular, is in a very favorable position to take advantage of the new commercial situation that will develop as so-called backward countries learn to produce more. Why? Because the United States is preeminently the country that is able to produce, and to produce efficiently, the kinds of goods that are wanted in an environment where people are building and developing. This includes electrical equipment, vehicles, transportation equipment, earth-moving equipment, and many other things of that sort. Also, America is particularly able to cater to peoples who are able to afford radios, refrigerators, and similar goods. We are in a better position than any other country to profit in immediate commercial terms from an increase in the average income level of other peoples. On the other hand, we are not very good at competing in the ultra-cheap markets of impoverished peoples.

Some years ago a German inquiry compared the amounts of various kinds of goods sold in international trade in 1913 and 1929. Some goods, such as cheap textiles, increased relatively little in total trade value. Others, especially new items such as phonographs, radios, and electrical goods, showed very great increases. They were "dynamic" goods. The same inquiry then compared the percentage of these different kinds of goods in the exports of England, Germany, and the United States. The result was striking. The "dynamic" goods which had increased more than 150 per cent in international trade between 1913 and 1929 comprised only four or five per cent of the exports of England and Germany in the latter year. But they made up about 30 per cent of United States export trade.

We are pre-eminently a country equipped to produce the "dynamic" kinds of goods that will be demanded in a world that is making economic progress. Thus, it so happens—and this may prove very significant—that the United States, whose governmental policies and business decisions will have the greatest influence in determining whether or not there will be vigorous economic development throughout the world, is also a country whose direct commercial prospects are most favorably influenced by world economic development and rising income levels in the rest of the world.

Now, what will the development of new productive capacity in Asia mean in terms of new competition for American producers? For, as I said, there will be both new competition and new market opportunities. The new competition will manifest itself in certain lines and the new markets in others. That gives the clue to what our policy ought to be. We ought to be adaptable, ready with initiative and adjustability, and we should expect to shift gradually, year by year, out of certain lines which will be more cheaply produced by other peoples, and into lines where new market opportunities will develop as incomes rise. That, I think, is the essence of a wise policy for American business, labor and government. It will benefit both us and other peoples.

The lines we must expect to abandon, gradually, are those that require a large proportion of more or less crude labor power. We should expect to import rather than export them. The lines where American industry can expect to expand to compete successfully are those requiring highly complex machines, scientific research, much capital in relation to the amount of labor, highly trained labor and highly skilled technical management. We can also excel in development of new products and new processes. Our true competitive strength is in keeping at least one jump ahead of the game.

The great lesson from the history of organic evolution is that it is the adaptable animal that survives and prospers, not necessarily the biggest, or the one with the thickest skull. The same principle applies in a changing world economic environment.

Rubber Is Coming In

The first shipment of crude natural rubber to arrive in New York from the Straits Settlements and Java since 1942 reached port on December 22 with the arrival of the SS Canton Victory, for which the Isthmian Steamship Company, United States Steel Subsidiary, is berth agent. The shipment contains over 8000 tons.

Shipments of crude rubber to this country were cut off by the Japanese invasion in the Pacific early in 1942. The last shipment to arrive from Java was also an Isthmian vessel, the SS Steel Worker, which arrived on February 25, 1942. Company officials said another vessel is due to arrive in January with a rubber cargo, and it is anticipated that there will be regular arrivals thereafter.

In the June, 1945, issue of Pacific Marine Review we published an analysis of the prospects for post-war rubber consumption. In our February issue there will appear a further analysis prepared in the light of subsequent developments.—Ed.

Pacific WORLD TRADE

Chinese Commodities

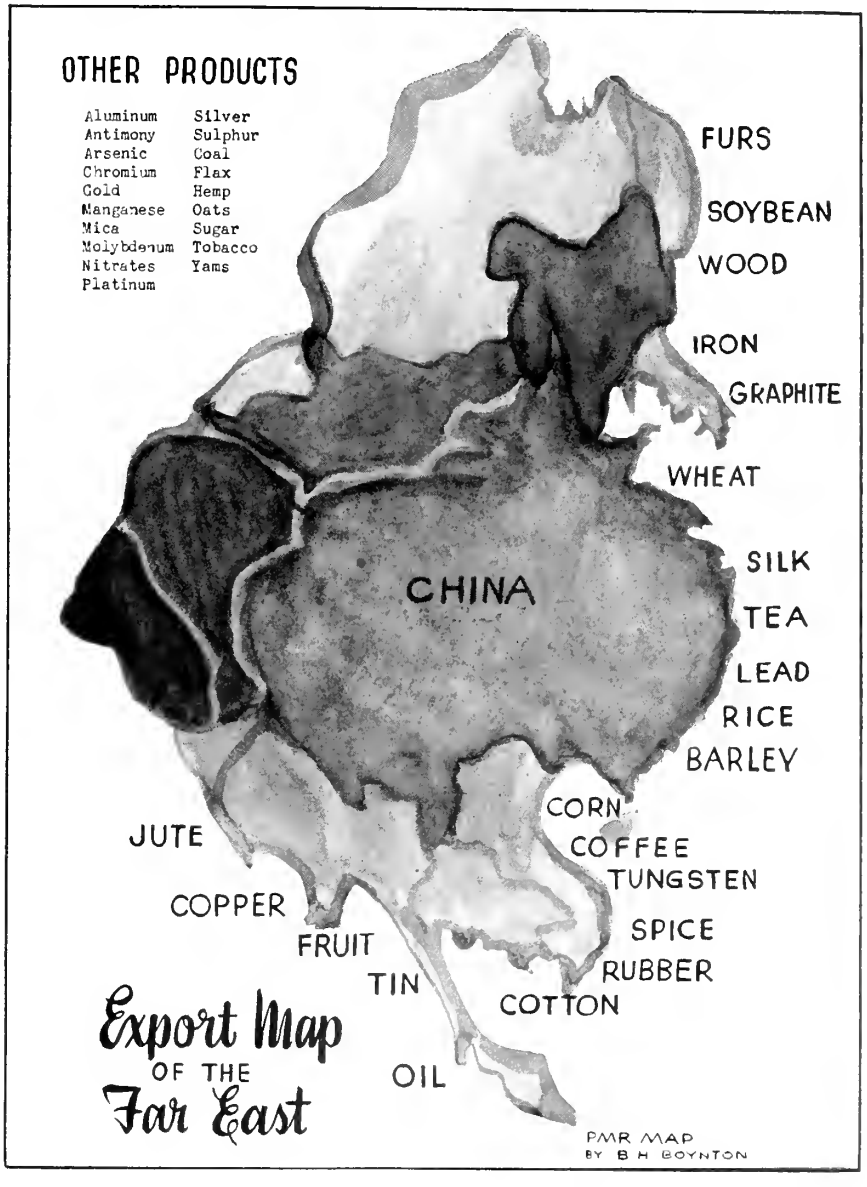
Estimates of the volume of Chinese commodities available for shipment from China have been received by the China - America Council of Commerce and Industry from official Chinese sources. These figures, which are the first official estimates of post-war Chinese exports to be received in this country, show that after a transition period to allow for revival of production and transportation in the formerly occupied areas, China will be able to ship considerably larger quantities of her basic export commodities than before the outbreak of the Sino-Japanese war in 1937.

Estimates of available export commodities were requested of the Chinese government for two main reasons. In the first place, many of the Council's import member firms are vitally interested in obtaining Chinese commodities for sale in the American market at the earliest possible moment. Secondly, the availability of export products will be the major factor in China's ability to service the large loans and credits she is expected to receive in this country and also to make cash purchases here. Because of the tremendously difficult problems involved in taking over the formerly occupied areas in Eastern China and surveying the available resources and plant facilities there, it has not been possible to get any realistic estimates up to this time. The report just received from China indicates encouraging possibilities, although many obstacles will have to be overcome before the Chinese export trade reaches its pre-war levels.

Importers in the China - America Council are encouraged by the fact that since V-J Day the Chinese Government has taken a number of significant steps to stimulate China's export trade. These include elimination of wartime government monopoly controls on the wholesale trade and export of tung oil, tea, bristles, silk and wool; lifting of embargoes on 29 export articles; cancellation of all wartime rulings regarding blockade lines and occupied areas, and the establishment of customs collections only at national boundaries.

It is expected that to an increasing extent the Chinese export trade will be handled by private interests. Chinese authorities state, however, that the commodity testing bureaus set up by the government for the purpose of improving the quality of the principal export items will be continued in operation after the war. These bureaus are expected to be of great value in helping Chinese exporters process, style and pack export prod-

Exports from the Orient. This tells only part of the story. Also from China come tung and other wood oils, peanuts, walnuts, egg products, fish, toys, hair, ivory, jade, bristles, bamboo, works of art—and firecrackers.



ucts meeting the requirements of foreign markets.

Tung Oil, Silk, Wool, Tea, Tin, Hides

Among the major Chinese export commodities for which considerably increased shipments are predicted in the post-war years as compared with the pre-war period, 1935-1937, are tung oil, bristles, raw silk, wool, tea, egg products, tin and antimony. Large shipments are predicted also of other well-known Chinese staples, such as sausage casings, hides and skins, oil seeds, beans, feathers, medical substances, hemp, jute and ramie, and tungsten ore. Certain manufactured products which have found a large market abroad before the war are also expected to figure prominently in the post-war export list. This applies particularly to such items as handkerchiefs, linens, embroideries, lace and hairnets.

In the three years before the Sino-Japanese war, exports from China proper (not including Manchuria and Formosa) averaged $222,000,000. Judging by the latest estimates, it should be possible to exceed that total within a few years. In the first year after resumption of regular trade, however, shipments are expected to be considerably below the pre-war figure for most items.

In the 1935-1937 period the United States took a little over a quarter of China's exports. Chinese authorities agree that in the post-war period a much larger proportion of their exports will go to this country. To help pay for the vastly increased purchases planned in the United States for the Chinese industrialization program, China will make special efforts to develop the export of those items which are in good demand in this country.

A continuing favorable market, for example, is predicted for tung oil, shipments of which to the United States averaged $14,000,000 a year in the pre-war period. The same is true of wool, of which the United States formerly imported more than $4,000,000 worth a year from China; and of various furs, hides and skins, of which we purchased more than $10,000,000 worth a year. China before the war exported raw silk to this country to the value of more than $4,000,000 a year. Despite the decreased over-all consumption, it is believed this figure can be considerably exceeded because of weakened Japanese competition. Similarly, hog bristles, of which China formerly shipped to this country around $4,000,000 worth a year, are expected to find a brisk demand notwithstanding the recent development of the synthetic variety in the United States.

Vegetable seeds and oils, including tea oil, sesame seeds, perilla oil, peanut oil and cotton seed oil, are expected to enjoy substantial sales in this country. In 1935-1937 U. S. imports of these Chinese items exceeded $6,000,000. In the pre-war period, China shipped to this country each year handkerchiefs, embroideries, laces and trimmings and hairnets to the value of approximately $6,000,000, and American importers are again actively in the market for these materials. Egg products from China, which added another $2,000,000, are also expected to have a large sale. Certain minerals and ores of which China is the major producer, particularly tin, antimony and tungsten ore, will again be available. The United States formerly took from China more than $5,000,000 a year of these three items.

Manchuria

In addition to China proper, Manchuria and Formosa, now under Chinese control, will provide a large volume of goods for export. In the three years prior to the "Mukden incident" Manchuria alone exported an annual average of $150,000,000 of its products to other nations and to China proper, most important of which were soya beans, bean oil and cakes, coal, millet and corn, and iron and steel. In the years before Japanese occupation, Manchuria enjoyed a substantial excess of exports over imports and helped to balance the total trade of China. Under Japanese domination exports continued at a high level, but Japan took an increasing proportion of the total, amounting to 55 per cent in 1939. About 15 per cent was exported to China proper.

Although exports from Manchuria will probably decline in the first post-war years, due to decreased production, increased domestic consumption, and reduced shipments to Japan, they will still be substantial. In the past years only an insignificant proportion of Manchurian exports went to this country.

It is expected, however, that in the future such products as raw silk, and hides, skins and furs will be shipped to the United States in increased quantites.

Formosa

In 1936-1937, Formosa's exports, mainly agricultural products, were valued at an annual average of $115,000,000. The bulk of these shipments went to Japan in exchange for manufactured goods. Formosa's exports in post-war years will continue to be large but for some time much of her sugar, rice, forest products, and alcohol, which constitute the bulk of her exports, will be required for shipment to the mainland of China. Nevertheless, it is predicted that exports of tea will be expanded and that the United States will buy more than in pre-war years.

While the import trade from China presents promising possibilities, the China-America Council points out, a number of obstacles must be surmounted before trade relations can be resumed on any substantial scale. Important among these is the question of stabilization of Chinese currency and the establishment of a reasonable exchange rate for the American dollar. Reports from China indicate the government is taking temporary measures to ease this situation so that exporters may begin to resume shipments abroad in the interim period before a new exchange ratio is finally established.

Another current stumbling block to resumption of trade is the lack of transportation facilities both within China and for overseas shipments. Although limited cargo space has recently been made available for shipments from this country to China, the problem of cargo space for shipments in the opposite direction is still to be worked out.

Training of Chinese Technicians in U. S.

Every engineer, every mechanic, every industrial planner who returns to China with American training will have a part in influencing the use of American machinery and other American products in China's brightening future. Those who aid in the training of Chinese students are promoting foreign relations—and foreign trade.

—Ed.

The United States played a major part in training the technicians urgently needed for China's war effort and for her tremendous post-war rehabilitation and industrialization program. Since 1942, approximately 1000 senior Chinese technicians have been sent to this country to gain practical experience in American technology and industrial management. In addition, at the outbreak of the war about 2000 Chinese undergraduate students were registered in American colleges and universities.

The industrial training work has been financed and supervised by the American and Chinese governments, by UNRRA and by unofficial organizations. Programs financed from American lend-lease funds have been supervised by the Foreign Economic Administration in cooperation with Chinese authorities. Those paid for originally by the National Resources Commission of China have been conducted by the Chinese-government-owned Universal Trading Corporation, though the State Department and FEA also extended their good offices. Ather programs have been supervised by various agencies of the Chinese government, including the Chinese Supply Commission and the U. S. representatives of the Ministry of Agriculture and Forestry, the Commission on Aeronautical Affairs and the Chinese Naval Construction Mission.

In 1945 Congress appropriated $4,800,000 to enable FEA to bring Chinese professional and technical workers to America for fractional crafts training in industry. Selection of the technicians in China was by examination held by Chinese governmental agencies. Three types of training courses of different lengths up to eighteen months, were designed: (1) professionalizing courses for top management in functional engineering fields; (2) industrial supervisors, and (3) technical visual education to pre-

(Continued on next page)

Montgomery Heads World Trade Association

William L. Montgomery, regional director, China-America Council of Commerce & Industry, Inc., has been elected president for the year 1946 of the World Trade Association of the San Francisco Chamber of Commerce.

Other officers elected were for first vice president, Fred B. Galbreath; for second vice president, R. J. Roesling; for third vice president, L. I. McKim; for treasurer, P. A. Kinnoch; for secretary, Alvin Eichholz.

William L. Montgomery

TRAINING OF CHINESE TECHNICIANS

(Continued from preceding page)

pare the trainees for the development of training courses in China. All lend-lease trainees were obligated to return to China to reengage in work contributing to the war effort. Trainees were not permitted to accept salaries while in America. Where agreements with unions provided that apprentices must receive pay, the wages were automatically turned back to the FEA Training Section. FEA provided $5 per day per trainee for maintenance and also insurance coverage. The length of service with any company depends upon the particular type of training.

Under contract with both FEA and the National Resources Commission, the International Training Administration has been engaged to handle arrangements for living accommodations, transportation, clearance with governmental agencies and related details, as well as assistance in placing trainees in industrial enterprises. The China-America Council of Commerce and Industry has cooperated with both American and Chinese authorities in bringing the programs to the attention of member firms and in facilitating placement of trainees.

Many of the Chinese trainees who arrived during 1943-1944 had completed their schedules prior to V-J Day and were returning to China as rapidly as transportation facilities could be made available. Other senior personnel were recalled immediately after the sudden Japanese surrender, some leaving by plane for China in September and others following by steamer in October. Paradoxically, the largest groups of Chinese trainees, totaling 850, arrived in the United States almost at the war's end. Because of transportation restrictions incident to the deployment of American troops, most of this large group of trainees has been placed initially with American industrial concerns on the east coast.

The Ministry of Education has decided to hold an examination for students going abroad to study in the early part of 1946. The examination is open to government as well as privately supported students. The number of government-supported students will be increased to 1000 and the countries for study will no longer be restricted to the United States and Great Britain, it has been announced. The Ministry is recalling the students who have completed their studies abroad to aid in the rehabilitation of China.

These wartime training programs and the fact that a large proportion of all Chinese engineers are American-trained, constitute a solid foundation for Sino-American industrial collaboration in the future.

Bottleneck In Financing Foreign Air Cargo

By *A. M. Strong*

Vice President, American National Bank & Trust Company of Chicago

International trade by air cannot be developed without adequate financing, the author states. To finance air shipments banks require an airway bill conveying title to the merchandise. He points out that airway bills presently used are not instruments of title, and recommends immediate steps to remedy the present situation.

Three basic elements play an important part in the development of modern commerce; the demand and supply of goods, availability of credit, and transportation facilities. The history of transportation is the history of commerce. A close parallel can be drawn between the development of primitive barter into modern international trade, and between the development of transportation from the camel caravan to the modern plane.

A. M. Strong

The role of air transportation in foreign trade cannot be measured by present standards. There are sufficient indications that carriage of goods by air will have a profound effect on international commerce. It will bring changes in our marketing methods and in our methods of financing. It will release capital tied up in merchandise in transit and in inventories. It will reduce the speculative element in foreign trade by making it unnecessary to purchase goods long in advance of seasons and it will reduce the cost of financing by reducing the turnover time between purchase and distribution.

Financial facilities are of paramount importance to the development of international air cargo. Foreign trade is not conducted on a cash basis. It is arranged primarily on a credit basis. Banks have established an efficient mechanism for these transactions. Through the Irrevocable Letter of Credit they underwrite a buyer's promise to pay for the goods. Through collection arrangements they retain custody of the goods shipped until payment is received.

American importers as a rule establish Letters of Credit in favor of the foreign sellers. The Letter of Credit is an undertaking by a bank to pay drafts accompanied by shipping documents or other documents

of title. The importer pays for the goods when the draft and documents are received by his bank. Quite frequently the credit is established on a time basis; that is payment is made within a specified time after the documents have arrived. Exports are usually made on a draft basis; that is, the exporter draws a draft on the foreign buyer and turns over the draft and shipping documents to his bank for delivery to the seller against payment. Such drafts are frequently discounted by the seller's bank, enabling him to receive cash long before the foreign buyer pays for the goods. In either case, the underlying merchandise is used as security for the transaction through the hypothetication of the shipping documents.

The documents in ocean traffic give the bank as consignee, or holder of the negotiable bill of lading, title to the goods. Unless a bill of lading conveying title is employed in air traffic, banks will not be able to finance air cargo on the same basis as they finance ocean cargo. The non-negotiable bill of lading used by air carriers consigning foreign cargo to an intermediary does not meet the requirements of bank financing as the document does not convey title to the goods.

The problem of financing of air cargo did not arise during the war period because most of the commodities transported by air were for Government account. The volume of private shipments was rather small. Air transportation of cargo, however, is entering the international field on a wide scale.

Three leading air lines have recently obtained permission to fly across the oceans to many foreign lands. These lines will operate throughout Europe, the Near East, India, Turkey, North Africa, Egypt and other countries.

A warning that the non-negotiable bill of lading employed by air carriers does not meet with bank requirements, was sounded at the Annual Convention of the Bankers Association for Foreign Trade, held at Montebello, Canada, in June of last year. A report submitted by the Committee on Uniformity in Documents and Practices pointed out that bank financing normally requires suitable documentation, including an airway bill giving the consignee clear title to the goods and that the airway bill presently used does not meet these requirements. The report further pointed out that the provisions made by certain airlines for consignments to intermediary agencies may create legal complications in the event of a dispute between the bank and the ultimate consignee. The report recommended that a coordinated effort be made to devise a uniform negotiable or non-negotiable airway bill, suitable for bank financing, and that comprehensive uniform laws be adopted with regard to international air shipments and the documents relating to such shipments.

International air traffic between the United States and the leading foreign countries is governed by the Convention for the Unification of Certain Rules Relating to International Transportation by Air, concluded at Warsaw on October 12, 1929, and known as the Warsaw Convention. The articles of the Convention deal only with the non-negotiable airway bill as the financing of air cargo was not a problem in 1929.

Pacific WORLD TRADE

Some doubt, therefore, exists as to whether under the rules of the Warsaw Convention, a negotiable bill of lading would be effective when the place of departure or arrival is situated in a country that is a party to the Convention. Air carriers should clarify the situation without delay, and if a modification of the Warsaw Convention is necessary, no time should be lost in bringing about such a modification.

The matter of air shipping documents was sadly overlooked in recent international conferences on air traffic. It is most important that air carriers take cognizance of the fact that lack of proper documentation has created a bottleneck in the financing of air shipments which may constitute a major obstacle in the development of air cargo. Steps should be taken through the existing international organizations or if necessary, through a special committee to devise and introduce a uniform negotiable airway bill.

Stanford and U. C. Offer World Trade Courses

Stanford

With the return of full pre-war enrollment, the Graduate School of Business at Stanford University is offering a course in International Trade — January through March — for second-year graduate students. Dr. Eugene Staley, lecturer in international trade at the Graduate School, and Director of the Institute of Pacific Relations for the Bay region, will be the instructor.

The course will include export-import practices, supplemented by visits to trading and shipping firms in the Bay Area, together with industrial development plans abroad.

U. C.

To meet the increased demand for current information on the techniques and regulations in the conduct of import and export trade, the Bay Area World Trade Promotion Committee, under the chairmanship of Charles Romanowitz and in cooperation with the Extension Division of the University of California, has completed arrangements to hold an Institute of World Trade, January 24, 25, and 26, at the Extension Division's auditorium, San Francisco.

With the increasing awareness of the importance of world trade in the future business economy of the Bay Area, executives of hundreds of manufacturing concerns plan to avail themselves of this practical information. A description of the services and facilities available in the Bay Area to assist in the promotion and handling of world trade will also be presented.

More than a dozen experienced foreign traders will give the benefit of their practical experience to assist manufacturers at the sessions in establishing their foreign trade policy immediately, and plan now to enter foreign markets.

Registration fee for the series, including copies of all talks, will be $12, with special consideration being given to servicemen interested in this field, whose registration fee will be $7.50. A brochure outlining the series of talks will be available on request shortly.

Latin America Offers Huge Market for West Coast Products

Grace Line Official Returns with Optimistic Report

In our December issue we featured the post-war ships and routes of the Grace Line. Mr. Thompson's report indicates real prospects for the Line.

Vast markets for Pacific Coast industrial products, including household appliances, foodstuffs, machinery, chemicals and metal products, await the Pacific Coast manufacturer and distributor in Latin America.

This is the message that Harry Thompson, freight traffic manager of the Grace Line, brings back from a 25,000-mile trip in which he visited 600 firms and prospective buyers in 13 Central and South American countries.

"Almost without exception every area I visited requires large quantities of consumer goods," said Mr. Thompson upon his arrival in San Francisco, "and primarily important, the majority of the countries have adequate gold credits in the United States to buy and pay for the goods they want.

"Prior to the war, shipments from the Pacific Coast states consisted largely of raw materials. The war years went a long way toward transforming this area from an agricultural to an industrial area. The Latin American buyers now are beginning to realize that they can make the purchases they want from Pacific Coast firms and feel that with fast, regular service and the ability to make shipping connections they can purchase advantageously on the Pacific Coast.

"My travels, beginning in August and continuing into December, convince me that Latin American exports and imports will shortly exceed the pre-war tonnage by a wide margin. The importers and exporters in many of the countries are definitely looking to the West Coast of United States and Canada as a source of supply of manufactured goods and as a market for their own raw materials. Many representative Latin American firms, however, do not realize that a tremendous change is taking place on the Pacific Coast in the manufacture of new products, although quite generally they express preferences for purchasing on the Pacific Coast when materials are available. Through the years they have enjoyed a very satisfactory relationship with West Coast business and now they evince a desire to extend this relationship into manufactured products of all kinds."

Harry Thompson, Freight and Traffic Manager, Grace Line, San Francisco.

In discussions with Latin American buyers, Thompson stated that he found a deep interest in such items as chemicals, hardware, refrigerators, radios, electric irons, building materials, iron and steel products, petroleum products, foodstuffs, flour, canned goods, wheat, machines for fish canneries, hydraulic and sanitary equipment, newsprint, paper, paper products and pulp. His records really show hundreds of items which the Latin American countries may be expected to buy in the early post-war period. These items he tabulated in his travels through Mexico, Guatemala, San Salvador, Honduras, Nicaragua, Costa Rica, Panama, Canal Zone, Colombia, Ecuador, Peru, Bolivia and Chile.

"Any firm interested in selling new lines of merchandise in the Latin American markets," said Mr. Thompson, "will find it advantageous to send their representatives with complete information on the new merchandise into these areas. I feel that they will find many opportunities and

that everywhere they will be favorably received."

Looking to an upsurge in trade between Pacific Coast and Latin America, Fred L. Doelker, vice president of the Grace Line, San Francisco, said that Grace Line will definitely assign a minimum of five C-2's to this trade, providing two sailings a month. These vessels have a carrying capacity of approximately 10,000 tons each, with ample refrigeration space. They are to sail in regular service between Canada, the Pacific Northwest, San Francisco, Los Angeles and ports on the coast of Latin America. They will serve every market from Manzanillo, Mexico, to San Antonio, Chile.

R. Ranney Adams, new president of Grace Line.

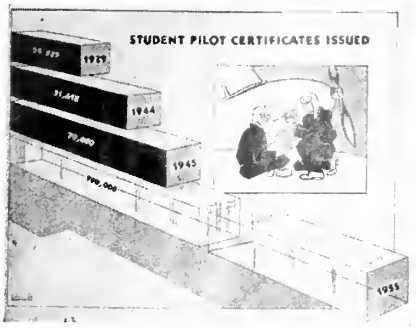
First "Santa" Ship Returns to South American Service

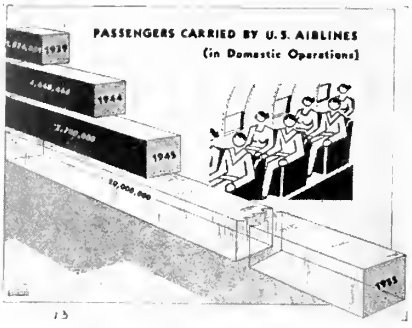
The arrival of the Grace Line freighter, Santa Leonor, in New York December 23 with 8 passengers and 9300 tons of copper from Chilean ports marked the first of the famous "Santa" fleet to return to Latin-American service. Regular passenger service on this route, however, will not be resumed until later in the year.

From her launching in April, 1944, until her present trip, the Santa Leonor had been assigned by War Shipping Administration to transportation of military supplies. She completed six voyages to the European theater of operations with U. S. Army cargo and recently returned to San Francisco from Okinawa on her first Pacific venture.

At all ports of call in Central America, Colombia, Ecuador, Peru, and Chile, the Santa Leonor was hailed enthusiastically as a symbol of the return of Inter-American trade to peacetime channels. Since the ship is designed for cargo carrying and has no troop accommodations she has been allocated by War Shipping Administration to continue in the New York-West Coast of South America service.

In command of the Santa Leonor is Captain Olaf Berg of Seaford, L. I., who was Master of the Santa Catalina, a sister ship, which was torpedoed and sunk on April 23, 1943, in the Caribbean.





The Growth of the Airlines

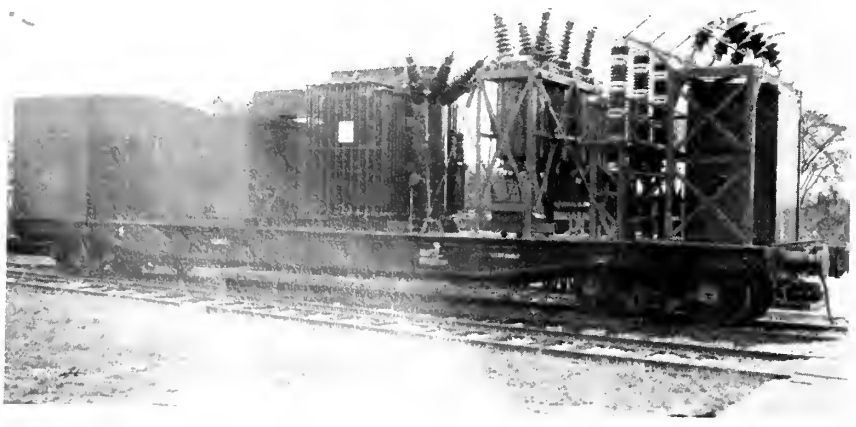
Railroad-Mounted Unit Substations For U.S.S.R.

The first of 15 railroad-mounted unit substations, recently completed at General Electric's Pittsfield Works for the Union of Soviet Socialist Republics, will be used in the rehabilitation of towns and cities that were devastated by war. It is believed that these are the first complete distribution substations of the railway-type to be built in America. Completely mobile, they will serve the electrical needs in war-torn areas and maintain service until permanent substations can be built for these areas.

The entire unit substation, permanently mounted on a flatcar, weighs 111,000 pounds. It contains a 46-kv incoming disconnecting switch, an oil circuit breaker, lightning arresters, a power transformer, and three outgoing 15-kv metal-clad switchgear circuit breakers and feeders, which include potential and current transformers for metering and relaying. Outgoing cable connections are through the floor of the car. There is also an auxiliary generator with control equipment to supply auxiliary power, heat and light while the unit is being readied for service. On one end of the car is the storage compartment containing tools required for maintenance and repair, and also such spare parts as bushings and lightning arresters. The unit is rated 1800 kva with a high voltage of 35,000 volts, which can be stepped down to 3150 or 6300 volts.

While being moved on American railroads, the trucks on the car are standard American gage, but wider Russian trucks are being shipped with the unit to be installed at the port of entry.

G-E mobile unit substation permanently mounted on railway car. Rated: 1800 kva, 3-phase, 50 cycles, 35,000 to 3150/6300 volts.



For Sale! . . . Lend-Lease Machine Tools

American lend-lease machine tools are being offered for sale in Australia on the same general formula as they were sold in Britain—at roughly a quarter of their original cost. Eighteen months ago the British Government made an over-all agreement for all categories of lend-lease tools and bought them at less than 25 per cent of their original value. Allowance was made in this price for heavy depreciation on machines supplied early in the war, also for machines lost on the Atlantic. In Australia, depreciation does not represent such a large figure, since all such tools are late models and little was lost crossing the Pacific. Thus, although the formula will be the same, the over-all price will work out at more than 25 per cent of the original cost.

Royal Navy Opens Hong Kong

Hong Kong, most important port of the Far East, has now been cleared, and is receiving commercial traffic. Six weeks after arrival, the Royal Navy cleared a wreck and debris from the drydock and docked an 8000-ton oiler for screw repairs, in spite of the fact that most of the dock yards had been destroyed.

Building work has recommenced on a 1000-ton ship which was left unfinished on the slipway. Harbor fairways are now cleared and are being re-buoyed and lighted. Twenty visible wrecks in the harbor and a large number of sunken wrecks are being moved. Minesweepers clearing the approaches to the harbor swept and sank 23 moored mines in one day.

In Congress—

Some Good Points Raised by Representative Welch on the Ship Sales Bill and on Ship-Air Operation in the Following:

Mr. Speaker, the bill under consideration, H. R. 3603, has for its principal purpose the sale of surplus war-built vessels. During its protracted consideration by the committee I endeavored at all times to use as my chart the declaration of policy contained in the Merchant Marine Act of 1936, referred to as the magna carta of the American merchant marine. This policy is reaffirmed in section 2 of the present bill. It cannot be referred to or read too often:

Sec. 2. (a) It is necessary for the national defense and development of the foreign and domestic commerce of the United States that the United States have a merchant marine (1) sufficient to carry its domestic water-borne commerce and a substantial portion of its water-borne export and import foreign commerce and to provide shipping service on all routes essential to maintaining the flow of such domestic and foreign water-borne commerce at all times; (2) capable of serving as a naval and military auxiliary in time of war or national emergency; (3) owned and operated under the United States flag by citizens of the United States; (4) composed of the best-equipped, safest, and most suitable types of vessels, constructed in the United States and manned with a trained and efficient citizen personnel; and (5) supplemented by American-owned facilities for repairs, marine insurance, and other auxiliary services.

(b) It is hereby declared to be the policy of this act to foster the development and encourage the maintenance of such a merchant marine, and to facilitate the adjustment of the merchant marine from war service to peacetime operations.

Mr. Speaker, before the war the world had about 74,000,000 deadweight tons of shipping. At the present time the United States alone has between 56,000,000 and 57,000,000 tons of shipping, costing $17,000,000,000. Before the war we had 11,000,000 tons. The following number and types of ships are now owned by the United States Government and are under the control of the Maritime Commission:

C-1 type	110
Concrete C-1	22
C-2	218
C-3	146
C-4	75
P-2	19
Special and combinations	34
Liberty	2,500
Victory	527
Tankers	530
Liberty tankers	60
Small type tankers	90
Total	4,324

Out of this total of 4,324 ships there should be a ready domestic market for the 2, 3, and 4 C-types of ships, the special and combinations, and, perhaps, the tanker types. This is about 25 per cent of the ships owned by the Government.

The Libertys and other types of ships are far less desirable. They are either too slow or do not contain the desirable cubic space. They were built for the war and did a good job, but are not economical or best suited for peacetime trade in competition with other maritime nations.

For nearly a year before the collapse of Germany, Britain was building specially designed ships for her peacetime trade. Further than that, she was not only building for herself, but she was also building ships for neutral Portugal's peacetime trade.

It is well known that Sweden took advantage of her neutrality and has built over a million tons of the finest merchant ships afloat.

For months past we have been building ships for the Netherlands. The Sun Shipbuilding Co., in its Philadelphia plant, is building ships for that country that are comparable to our C-3's, which is the best type of ships we have.

During the hearings on this bill lasting over a year, your committee has been confronted with two schools of thought with particular reference to sections 8 and 9 of the bill. Section 8 provides for exchange of war-built vessels by allowing a turn-in credit for old or antiquated ships. Section 9 provides an adjustment for prior sales to citizens, and it also contains an exchange provision.

Both sections are highly controversial.

One school of thought maintains that if the turn-in price is too low, owners of old vessels requisitioned by the Government will not negotiate with the Maritime Commission for war-built vessels, but will hold the Maritime Commission to its charter contract to put their old ships in class by reconditioning them. It was testified by the chairman of the Maritime Commission that this cost might run as high as $20 a ton. This would defeat the very purpose of the Merchant Marine Act of 1936.

The second school of thought holds the opposite view. Their conclusion is that if the Government allows too much for the turn-in value of old or antiquated ships, then the net return to the Government will be too low.

Mr. Speaker, while we are duty bound to get the best possible price for our surplus ships, we should also keep in mind that there is no law which compels an owner to turn in old ships for new ones. He will only do so if he feels he is getting just compensation for his old ship.

Mr. Speaker, the committee's task has been more complex due to the fact that the shipping interests themselves lack unity. They were divided into three groups — the subsidized operators, the nonsubsidized operators, and those not wanting a ship sales bill of any kind, in the absence of which they believed they would be able to buy our ships at any old

price, as was the case following the First World War.

During the First World War it cost the Government $200 a ton to build ships, and they were sold after that war for as low as $5 a ton. That should not happen again.

Mr. Speaker, the Maritime Commission has sent four bills to committees of Congress having this legislation in charge in both bodies. I am unable to state which of these bills is better or worse in some of their provisions. The first bill absolutely discriminated against American ship owners in favor of foreign-flag operators. This discrimination was, of course, rejected by the committee. The last bill contains a big-stick provision which would allow the Maritime Commission to give preference to purchasers of our vessels who, in the judgment of the Commission, play ball, as against those who have the courage of their convictions. This discriminatory provision, if written into law, would establish a precedent which could be used by every department of Government in the sale of surplus commodities and the settlement of war claims.

With all of our vast tonnage we will not be as well equipped as foreign nations to meet the needs of foreign trade. Their scarcity of tonnage will be rapidly remedied by building new ships specially designed to meet the requirements of the routes they are to travel. This fact in itself will place the American merchant marine at a competitive disadvantage.

But further than that, Mr. Speaker, the interpretation placed on the Civil Aeronautics Act of 1938 by the Civil Aeronautics Board has completely denied American ship operators equal opportunity of competition with every other maritime nation in the world. In denying the use of the air to our shipowners in foreign trade they have placed handicaps on the American merchant marine that create an unwarranted situation that can only be overcome by increased subsidies paid out of the pockets of the taxpayers of this country. This particularly applies to passenger and fast-express traffic.

There is no doubt that the Government through the Maritime Commission would have received very much higher bids for the American President Line, which it took over, were this line permitted the right to operate air travel parallel to its surface routes. This is the only American flag shipping company that has maintained an around-the-world passenger service and it had done this for many years prior to the war. As another result of the unwarranted action of the Civil Aeronautics Board there is no demand from American ship owners for the 19 P-2 war-built vessels owned by the Government. These ships cost $304,000,000. They are excellent fast passenger ships, built to carry more than 500 passengers. They are not desired by American ship operators because they expect the action of the Civil Aeronautics Board will reduce transoceanic passenger travel in American ships to a minimum.

How much longer will Congress permit the Civil Aeronautics Board to hold the American merchant marine in a straitjacket and lash it to the mast of restriction? No other maritime nation has or would tolerate such a board.

Those who would interpose objections to a ship sales bill have yet to raise their voices anywhere in defense of an American merchant marine, such as is proclaimed in the Merchant Marine Act of 1936, against bureaucrats in high Government positions who would reduce the American merchant marine to the level of a fleet of tramp steamers. The need for an adequate American merchant marine for our national security and peacetime economy is more necessary now than at any time in our history.

On Airport Bill (and Ship-Air Operation)

Mr. Speaker, I yield 10 minutes to the gentleman from California (Mr. Welch).

Mr. Welch: Mr. Speaker, I shall support this Federal-aid airport bill—H. R. 3615—which proposes to provide aid for the development of public airports.

The bill authorizes an aggregate appropriation of $650,000,000 to be spent over a period of 10 years beginning with the next fiscal year.

I have always been a strong advocate of the development of our air facilities to their maximum efficiency. Air development is a guaranty toward our national security, as the history of the recent war clearly proves. It is likewise a valuable asset in the development of our peacetime economy.

Mr. Speaker, it will be a relief to every Member of Congress who is interested in the development and maintenance of the American merchant marine to know that this act will be administered by the Civil Aeronautics Authority rather than the Civil Aeronautics Board. As I have heretofore pointed out, there are four interdependent principal links in the chain of our national defense—the Army, the Navy, the merchant marine, and our Air Forces. By its action in refusing the right to American ship operators to operate air lines parallel to their surface routes, the Civil Aeronautics Board has clearly demonstrated its inability to recognize this fact. On the contrary, its policies and actions tend to destroy one with the other. Too few people realize the seriousness of this situation. The United States Maritime Commission at the present time has 19 excellent passenger ships to sell which cost some $304,000,000. Each of these ships will carry more than 500 passengers. They are excellent ships to compete with foreign ship operators on surface routes. Because the Civil Aeronautics Board will not give the right to operate air lines parallel to surface routes, the Maritime Commission cannot find American ship operators to purchase these 19 ships. This is but a single illustration of the vast harm being done to our American merchant marine by the Civil Aeronautics Board.

Mr. Speaker, it was hoped by many Members of Congress that this bill might have been brought in with a rule sufficiently broad to lift the heavy hand of injustice that has been placed upon the American merchant marine by the action of the Civil Aeronautics Board in denying American shippers equal opportunity with every other maritime nation in the world. No other nation would tolerate such action.

It is to be hoped that first consideration will be given by the Civil Aeronautics administration in administering this act to publicly owned

and financed terminal airports, which are international in their service.

The city of San Francisco has been one of the most forward-looking in regard to airport facilities. Strategically located at the air crossroads of the Occident and the Orient, it has one of the finest airports in the world. Although some $20,000,000 has already been spent in its development, the voters of San Francisco will go to the polls next month to authorize another $20,000,000 bond issue for the further development of its airport facilities. Just as the port of San Francisco has been one of the world's greatest ports of embarkation in the war, so its great airport will be one of the keys to our future national defense in the air.

Mr. Speaker, this bill should be speedily enacted into law.

Advantages Claimed For Ceylon's New "Tea-Tablet" Method

Tea can now be reduced to tablets, which are cheaper to produce and transport than tea in bulk, according to the foreign press.

Rising costs of tea production in Ceylon led to an intensive inquiry by the Ceylon Tea Research Institute into manufacturing processes in that country, and this has resulted in the inauguration of a new method of producing fermented tea.

The new method is simple, eliminates withering, rolling and grading, and it takes only 2 hours as compared with 24 hours for the old method. The green leaf, on arrival at the factory, is pulped between stainless steel rollers, and the fermentation thus initiated is completed in an hour. The pulp is then dried in an ordinary tea drier and compressed in tablet form.

Tea tasters have reported the brew made from the tea tablets to be of unimpaired flavor and quality, and stronger than that made with loose tea.

Baker Announces South American Representative

The Baker Industrial Truck Division of The Baker-Raulang Company, Cleveland, Ohio, announces the appointment of George S. Forman as direct factory representative in Latin America for its line of power industrial trucks, tractors and cranes. Mr. Forman's wide experience in the export field and his knowledge of material-handling problems will be of definite assistance to prospective users of this type of equipment in the Latin-American countries.

Mr. Forman got an early start in the export business working as a boy for export commission houses specializing in Latin-American trade. After spending the years from 1915 to 1922 with the Pan American Trading Company, the G. Amsinck & Company, and in the U. S. Navy during World War I, he commenced traveling in Latin America, first for the Firestone Tire & Rubber Company, and during the past 17 years for Colt's Patent Fire Arms Manufacturing Company.

P. G. & E. Advertisement in Pacific Coast Newspapers Which Indicates the Kind of Industrial Cooperation That Will Build the West and Its Foreign Trade

Australia Seeks All-Time Record Food Production

An all-time record food production of at least 4,000,000 tons is demanded of Australian farms and factories this year. The total does not include grains or fresh vegetables for home consumption. Ending of the Pacific war is estimated to have increased the demand for food by at least 2,000,000 tons, bringing world food shortages to 8,000,000 tons. Half a million extra people have to be fed from the Australian Army cook-houses alone until Japanese prisoners can be sent home and civil administration restored in reoccupied territories.

Brady Brought Home Idea to Grow Rice

Because John Brady, Australian fruit farmer, noticed that the climate, soil and irrigation conditions in rice-growing areas of California were identical with the Australian Murrumbidgee river irrigation district, he has been awarded a Government grant of £300 (about $1000) for "special service in the establishment of the rice industry in Australia." In 1921 he visited California, became convinced that rice could be grown on the Murrumbidgee, and planted his first crop later that year. By 1924-25 production was 16,000 bushels, or 104 bushels to the acre—higher than the yield in some California districts. Last year's harvest of 75,000 tons helped feed starving native peoples in the Pacific.

Siam Replaces Thailand

The kingdom of Siam, which became Thailand on its own motion back in 1938, has officially become Siam again, and all mail to points therein should be addressed accordingly.

Excluding Liberty ships, the average speed of American merchant ships is today 25 per cent greater than in 1939.

Brazil to Buy Railway Material and Locomotives In the United States

The Government of Brazil has opened a credit of $19,550,000 for the purchase of railway material and locomotives in the United States. Of this sum, $7,250,000 is to be used for equipment and material necessary for assembling 2900 cars in Brazil.

Forty locomotives are to be type 4-8-4 and 10 locomotives are to be type 2-6-6-2.

Pacific Coast Rubber

GR-S synthetic rubber, the type used in tire making, is now being produced in sufficient quantities to supply all Pacific Coast factories. In the local operation, both rubber and latex are made from petroleum products piped from adjacent plants operated by Standard Oil Company, Shell Chemical Company, Dow Chemical Company, and the Southern California Gas Company.

The water clarification system, also included in the Rubber Reserve's investment, consists of an intricate series of skimmers and settling basins which eliminate all extraneous material from the waste water. Water is used in vast quantities to control temperatures in the reactor systems. The new clarification system purifies the water before it is run off.

The California Synthetic Rubber Project, consisting of six operating companies, was completed in 1943 and has produced almost 200,000,000 pounds of rubber since operations began.

Pacific WORLD TRADE

INDUSTRIAL COOPERATION

(Continued from page 46)

supplied many of the tools for their new industrial economy, including equipment for steel mills, for power plants, and for the electrification of their railroads, all of which will have important reflections on the lives of the people in that country. In cooperation with the Corporacion de Fomento of Chile, Westinghouse is aiding their plans for hydro-electric projects such as Sauzal and the Pilmaiquen plants. Work is being done with the Empresa de Energia Electrica of Medellin, Colombia, to expand industry in that country, most important at the moment being the Riogrande hydro-electric project. In Peru, also, Westinghouse equipment and technical ability is being made available to the Corporacion Peruana del Santa on projects such as the Canon del Pato hydro plant on the Santa River.

In Mexico the new industrial economy has made great strides. Westinghouse has supplied electrical equipment for large generating plants, including Ixtapantongo and Nonoalco, and will continue to cooperate with the Comision Federal de Electricided, who have undertaken a $20,000,000 electrification program. With this cheap public power made available, industries in Mexico which have been hampered by lack of power will expand and thrive, creating useful employment and greater purchasing power.

In line with the policy of industrial cooperation, Westinghouse will also aid in the establishment of a new $15,000,000 manufacturing plant in Mexico. To be called Industria Electrica de Mexico, this plant will manufacture all lines of electrical equipment under Westinghouse patents and designs. Technical assistance in the layout and engineering of the plant, together with a program to train a large group of operating personnel, will permit Mexicans to manage and operate their own business and thus enable them to incorporate locally available materials and labor into the products they consume, at the same time increasing their living standards and purchasing power. Incidentally, they will become intimately acquainted with American styles and standards and provide a wide market for precision subassemblies and other equipment made in the United States.

When this policy of industrial cooperation becomes more widespread, the United States will reach new levels of prosperity in company with other nations of the world. The export of technical skill, our most valuable resource, will bring a greater interchange of goods and keep our merchant ships busy plying the trade routes with full cargoes.

Steady as you go!

The Sextant

Chapter I

The evolution of the present-day sextant more than likely began with the astrolabe, used by early Greek and Arab astronomers. This astrolabe consisted of a circle suspended in the vertical plane by means of a ring at the top. The circle was graduated, or marked off, in equal divisions. The sighting bar was secured to the graduated circle somewhat as a compass needle, and by sighting along this bar at a celestial body and noting the scale on the circle, the altitude of the body could be measured. In the 16th and 17th centuries many variations of the astrolabe were in use.

In about 1594 a British navigator by the name of Captain John Davis developed a quadrant which had two arcs and required sighting in two different directions. Later a type of quadrant was used which required the observer to stand with his back to the sun. Other instruments depended on the use of a plumb line.

About 1729 one Pierre Bouguer devised an instrument which needed only a sight of the horizon while a beam from the sun was kept visible in line on a wooden peg. Another type of instrument shaped something like a T square was also in use about this time. In using this T square instrument the sun and the horizon had to be sighted separately. It could also be used either in facing the sun or with the observer's back to the sun.

In 1674 both Robert Hooke, a professor of geometry in London, and Sir Isaac Newton, working independently, worked out the principle of the double reflecting mirror instrument, but there seems to be no record of any models having been made.

Along about 1730 one Thomas Godfrey of Philadelphia, and John Hadley, a British astronomer, each working independently, constructed the first double reflecting instruments a good deal like our present-day sextants. In 1757 a Captain Campbell enlarged the arc used so as to make the instrument a true sextant. Up to about 1775 all sextants used were made of wood. Successive improvements in the sextant were made, and in the early nineteenth century the first all-metal sextant made its appearance. They were more or less crude affairs, accurate measurement of altitudes not being possible until the vernier used on the present-day vernier sextant was invented by Pierre Vernier.

In 1812 Commander Hull of the U.S.S. Constitution used a sextant which was fitted with shade glasses, a telescope, a vernier, and an ivory arc. Nathaniel Bowditch used a similar instrument, but with a silver arc substituted for the ivory arc. Some minor improvements followed, but the vernier type sextant is not radically different today from those used more than one hundred years ago.

A sextant is an instrument used to measure angles, whether the angle be (a) the angle of a celestial body above the horizon, (b) a vertical sextant angle, or (c) a horizontal sextant angle. **Regardless of what use it is put to it will only measure angles in degrees, minutes and seconds.** A sextant is particularly suitable for use at sea in deep water navigation for measuring the altitude (that is, the angular distance above the horizon) of celestial bodies because it may be held in the hand and accurate measurements of the angle obtained even though the ship be rolling or pitching. Inasmuch as the sextant may be used for observing angles in any plane or level, vertical and horizontal angles may be measured, and for this reason it is used in coastwise navigation.

The sextant derives its name from the length of its limb, which is the sixth part of a circle, or 60° (from the Latin **sextans**—"the sixth part"). There are two types of sextants in use. However, the difference between the two types is not in their principal construction, but is entirely concerned with fixing the index arm and reading the angles concerned. For convenience these models, or types, may be called:

(a) The Vernier Sextant.

(b) The Micrometer Sextant.

The vernier sextant is still greatly in use, and it differs from the other type in that accurate readings must be made by use of a vernier (to be described later), and, inasmuch as the divisions on the vernier are so fine and so close together, a magnifying glass must be used in order to "read" the sextant. Furthermore, considerable practice and skill must be used in order to read the vernier sextant accurately. Figure 1 shows the principal parts of the vernier sextant.

The micrometer sextant is the most modern type of instrument. It is equipped with a combined clamp and endless tangent screw by which means the index arm can be moved along the arc to show whole degrees of the measured angle, while the micrometer drum records the minutes, and tenths of minutes (which on the vernier type sextant are shown by the Arc and Vernier combined). The micrometer drum has the readings very clearly marked on it, and the observed angle can be read without the aid of a magnifying glass or any previous practice. Figure 2 shows

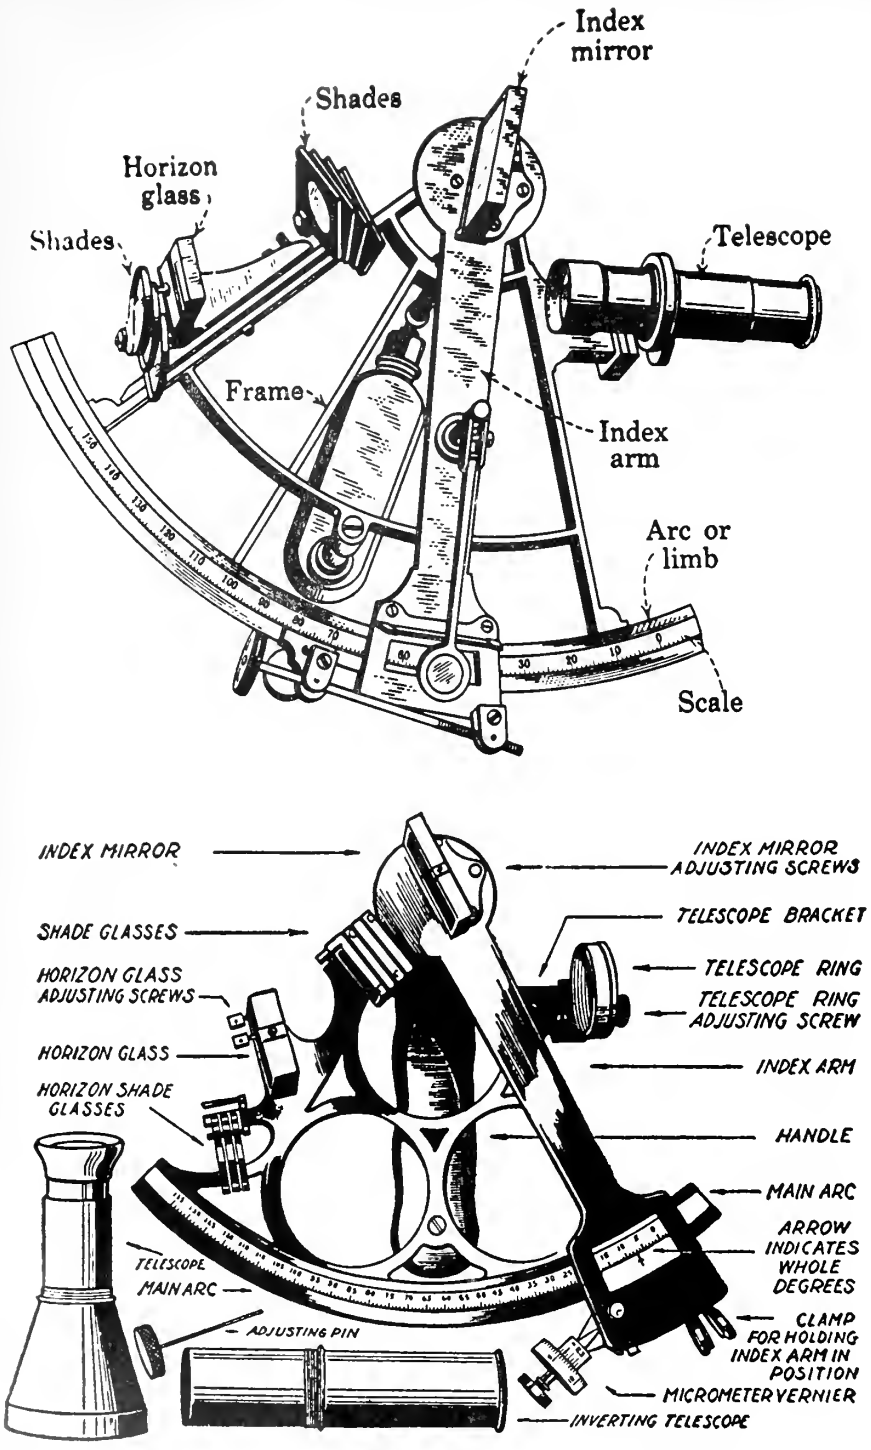

Fig. 1, upper: Vernier sextant. Fig. 2, lower: Micrometer sextant.

the principal parts of the micrometer sextant.

Description of Parts of the Sextant

Figures 1 and 2 show modern sextants in which most of the parts have been named. The upper flat surface of the sextant is called the **plane** of the **instrument.** The sextant itself may be said to consist of three main parts:

(a) The **Fixed** Parts.
(b) The **Movable** Parts.
(c) The **Removable** Parts.

The Fixed Parts of a Sextant Are:

(1) **The Frame.** The actual metal frame of the instrument may be one of several patterns, which are selected to give the greatest strength and rigidity. There is no advantage in having a very light sextant, as a fairly heavy instrument gives greater steadiness when taking observations on a rolling ship. At the back of the frame is fixed the handle, which may be of wood or Bakelite. The handle is important, as it must be able to be grasped—possibly for longish periods — easily and without fatigue.

The sextant should only be held by the handle or by the frame.

(2) **The Limb and Arc.** The limb of the sextant is really the lower margin or the whole of the curved circular portion of the sextant into which the graduated arc is bedded.

The **Arc,** on which the graduations are cut, is circular and made of metal with a low coefficient of expansion. It is usually made of a thin piece of silver (sometimes platinum) set in flush with the face of the sextant limb.

The Arc Proper is graduated in degrees from right to left from 0° (zero point) to 120° (and frequently to 130°, 135° or 140°). It should be mentioned that inasmuch as a sextant is an instrument of double reflection (as explained further on in the discussion on the Principle of a Sextant), the instrument is graduated to 120° or more, although the limb is actually only one-sixth part of a circle, i. e., 60°, as may be seen by reference to Figs. 1 and 2. To the right of 0° or zero on the arc, the arc is graduated from 5° to 10°, which is said to be **"Off the Arc,"** and is sometimes called the **Arc of Excess.** Readings to the right or left of 0° are therefore distinguished by being "off" or "on" the arc, respectively.

In the case of the vernier sextant, each degree on the arc of the sextant may be divided into two divisions of 30′ each; three divisions of 20′ each; four divisions of 15′ each, or six divisions of 10′ each. However, in most vernier sextants the degrees on the arc are divided into six divisions of 10′ each.

In micrometer sextants, however, each whole degree is cut boldly on the arc, each 10° being numbered and each 5° being indicated by a longer cut than those marking each degree. The micrometer in one revolution of the drum moves the index arm along the arc **one whole degree.** The micrometer itself is divided into **minutes,** and, when a vernier is used,

Seating of Brushes

A most common and reliable method of ascertaining that the face of the brush is in contact with the commutator over the entire area of the brush is by the use of sandpaper. To insure contact between commutator and brush over the whole face of the brush, cut sandpaper in strips slightly wider than one brush and lay this paper strip against the commutator with the brush riding on the sanded side. A coarse grade of sandpaper can be used for hard brushes until approximately full contact is obtained, but the final surface should be formed with sandpaper of a fine grain. It is important not to disturb the angle of the brush to the commutator and to the holder, as it must have the same position in the holder during sanding that it will have in operation. It is quite essential that the brush will show a substantial area of contact from the leading to the trailing edge. This area should be at least 75 per cent of the total area of contact end of the brush.

While roughing-in, using coarse sandpaper, it should be drawn back and forth under the brush face, but it is preferable during the final stage to draw the paper only in the direction in which the commutator moves. If the brush shows signs of tipping under the high friction of the sandpaper it must be held firmly against the side of the brushholder, against which it will ride when in operation. It is also important to see that the sandpaper is in contact with the commutator during the entire stroke, otherwise it tends to round off the edges of the brush.

Some machine operators prefer to use a brush-seating stone rather than sandpaper for fitting brushes to commutators or collector rings. This stone is a fine grain free-wearing stone of a special composition available from manufacturers of commutator equipment. It is held against the commutator or ring, close to the brush so that the commutator in moving tends to push the stone into the brush; pressure on the brush should be increased during this seating operation. The fine particles of stone worn away are carried under the brush face and grind it to the exact curvatures of the commutator. The stone therefore wears away very rapidly—almost like a chalk on a rough board. Although this method of brush seating may, and probably will, affect the commutator surface film, it is claimed by most authorities that no appreciable abrasion of the commutator surface proper results. A brush seating stone is considerably easier to use than sandpaper, and grinds the brush face to the exact contour of the commutator. Furthermore, it is not at all unlikely that in seating the brushes of one stud considerable effect will be found on the brushes of all the other studs as the particles of stone carry around the commutator and the temporarily roughened surface of the commutator also aids in finishing off the brushes.

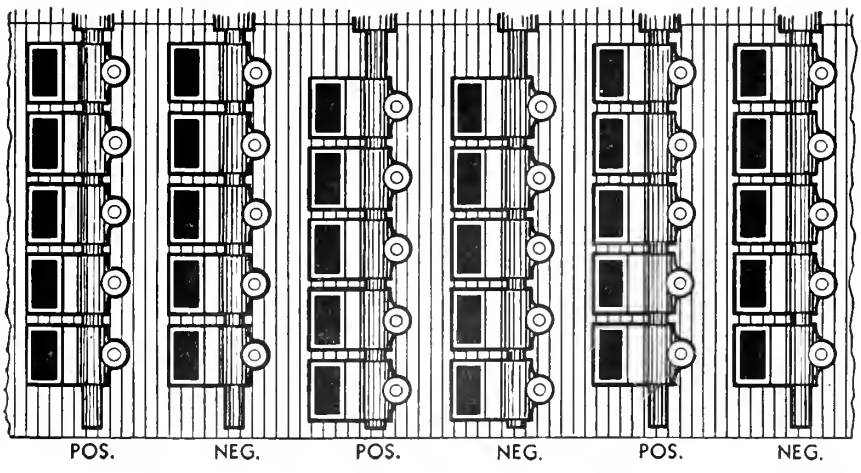
In organizing a brush-seating program, it should be noted that even though the contact area may be 1/2 or 2/3 when finished, it probably will be a matter of only a few hours of operation before the normal wear of the brush will have brought the seat to a 100% contact.

Brush Pressure

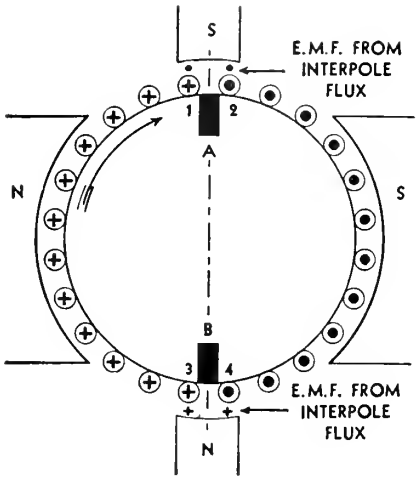
The spring pressure applied to brushes has a marked influence on the performance—after a new set of brushes has been installed and seated, the spring tension of all the holders should be adjusted to perform as closely as possible to the value desired. This spring pressure should be equalized among various brushes.

There is a natural tendency on the part of many operators to keep the spring tension low in order to reduce friction losses and brush wear, but the resulting effect may be exactly opposite to that intended. Too light a spring pressure may cause what is

Fig. 1



Correct Method of Staggering Brushes



Interpole Generator with Brushes at Neutral Point

Fig. 2

called "electrical wear" of the brush, which is caused from "sparking," resulting from lack of firm contact, which causes the brush to erode more rapidly than normal. Furthermore, lack of pressure on one brush as contrasted to that of another may cause unequal distribution of current among several brushes. It should be noted that the brushes of one polarity are electrically in parallel. The overloading on a brush may cause trouble which could be traced to lack of spring pressure on another brush.

Where severe mechanical vibration is encountered, a spring pressure considerably higher than what might be considered normal should be used. The more severe the vibration, the higher the spring pressure necessary to maintain firm contact at all times.

A small spring scale should be used for measuring spring pressure on brushes. The reading of the scale should be observed just as the brush leaves the commutator. A good method is to slip a strip of paper under the brush face and pull on it gently while lifting the brush spring with the scales. Reading of the scale should be taken when the paper is released by the brush pressure.

Brush pressures are recommended in terms of lbs. per sq. inch of area of the brush. This is not intended to refer to the area of the contacts at the commutator surface. It is to be noted that contact area will be larger than cross section area of the brush by the amount of the sine of the angle of the brush from a perpendicular line.

For general industrial and marine service, it is customary to hold not less than two and perhaps more in the order of three lbs. per square inch of brush area for the electro-graphitic brushes—less than this for the carbon and carbon-graphite brushes and a soft graphite brush, which are not usually found in marine service. A good figure for the marine engineer and electrician to keep in mind is 2½ to 3½ lbs. per square inch.

Location of Brush Position

Staggering of brushes has long been considered one of the most important factors in successful commutator life. However, this conception of brush location originated during the days when some polishing or erosive action was necessary. It was customary to mix in with the brushes a polishing medium, such as fine pumice stone or other material which would continually polish and burnish the commutator which was being continually spotted by sparking; therefore a continuous wearing away of the commutator was expected and it was natural that an attempt should be made to equalize the commutator wear and prevent ridges in the commutator from standing up, due to the fact that all of the commutator surface was not covered by brushes, if they were not staggered; thus by staggering of brushes, all parts of the commutator would be covered by brushes an equal amount and the wear would be uniform.

Modern brushes and commutators, however, should not under normal conditions require this polishing effect; the normal motor or generator should run along with a commutator having a nice polished dark film and years of life obtained without more than just the very slightest amount of wear. While the brushes may wear, the commutator should not require resurfacing, turning or grinding for many years of useful life, and the necessity of staggering the brushes has therefore been eliminated.

It has, however, been noticed that the appearance of the commutator, when the brushes are not staggered, will show dark brown in the brush tracks and the normal copper-colored narrow track between brushes. There may be no ridge or physical disturbance of the surface between these two tracks, but the appearance sometimes makes the operator nervous and gives the impression of a ridge. And of course there are commutators which due to some cause or other, such as a disturbing factor, may have slight wear, and it would appear to be desirable to distribute the wear uniformly over the commutator. In former days it was customary to see that the armature had a definite axial movement or end-play; on machines which would not necessarily float back and forth in the sleeve bearing, an end-play device was put on the end of the shaft to push it back and forth deliberately and keep it in motion, thus unifying and leveling the commutator wear. Since the advent of ball bearings which do not permit any end-play or axial movement, and also the non-abrasive brushes, this factor has also disappeared from the picture and axial movement is no longer expected nor required, although if present it should be considered as having no serious or undesirable effect. If possible, therefore, it is desirable to stagger the brushes as indicated in Figure 1.

With the brushes equally spaced around the commutator and aligned with the axial line of the commutator bars and otherwise properly adjusted, there remains only the question of circumferencial location of the brush studs, or the so-called "No-Load Neutral."

Machines having interpoles or commutating poles, and in marine service there are practically no exceptions, have a fixed neutral point. It is preferable from other considerations besides commutation that the brushes be set at this neutral, or at some specific point near it; for instance, with a direct current motor it is desirable to run at the same speed in either direction which would be determined by this brush setting; or with generators, it is desirable that they parallel properly, and this brush position determines paralleling characteristics quite decidedly. If commutation were the only factor influencing position of brushes, it would be a simple matter to shift the brushes backwards and forwards until the point of best commutation and minimum or no sparking was obtained. For instance, by the black-band method the brushes would be shifted in one direction until a slight amount of sparking was indicated at a given load, and then they would be shifted in the other direction until

the same amount of sparking was observed. The center, or halfway between these two points, would be considered the proper point from the standpoint of good commutation. If no spot can be found in which there is no sparking, then a problem of disturbing factors is involved, and an attempt should be made to find the trouble. This point will be discussed in later articles.

There are many ways of locating the so-called "No-Load Neutral," but the voltage method will be discussed, and the other methods only referred to. For the voltage method, it is advisable to use a multi-range voltmeter with scale 15, 1½ and .15 volts, or values of that order. Always start the readings on the high scale, changing to the lower scale only when such change is needed. With the machine operating without load, and at full speed and voltage, either as a motor or generator, the terminals of the voltmeter leads are placed in contact with the commutator at the assumed location of the neutral point, which should be approximately opposite the center of the main pole-phase. This test can be made with the brushes lifted, but would ordinarily be made with the brushes riding in a normal manner, operating as a motor or generator. These voltmeter contact points should be maintained at a fixed distance apart, preferably by pushing the probes through a cork or some other improvised method. The distance apart might be about the width of one bar or it might be the brush thickness. As this pair of contact points are moved back and forth, a position will be found at which the voltmeter shows the lowest reading. Centering the brushes on this position, the test should be repeated and the point so found marked as the "No-Load Neutral" of the machine. Sometimes it might be desirable to make a further check for this same point with the direction of rotation reversed if the machine is reversible.

The inductive kick method involves the measurement of a voltage induced in the armature windings when the main field circuit is opened or closed. This is done with the machine shut down.

The running neutral method is used only when the machine can be driven mechanically, such as with generators. It cannot be used on motors—current for excitation of the main field and also for interpole field is necessary.

The speed method involves operation of the machine as a motor and shifting brushes so that the exact speed in both directions is the same for a given load. A different neutral may be found for no-load and for full-load under this test.

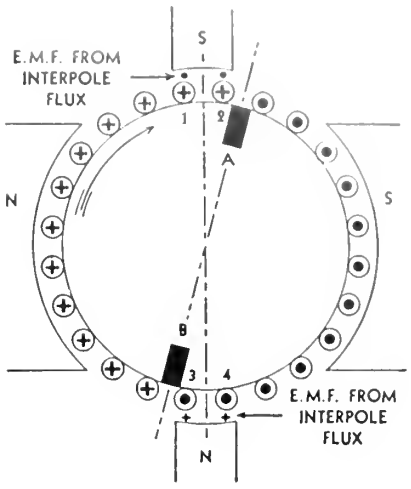
The terminal voltage method involves running the machine as a generator at exactly the same speed in each direction and adjusting the brush position so that the same voltage is obtained at this speed. Note that in reversing direction it is necessary to reverse the field with respect to the armature.

The torque method, useful on small motors, operates the machine as a series motor and adjusting the brushes so that the torque is the same in each direction for a given current.

One of the most important factors involved in brush shifting is the compounding effect of the inter-pole field; in other words, it is important to locate the brushes in a position in which the proper compounding effect is obtained regardless of other factors, unless the shift is too great and the borders of the commutating zone are past.

With the brushes of a generator on exact neutral, as indicated by the brushes "A" and "B" in Fig. 2, the voltage generated in the armature conductors under the inter-pole neutralizes itself. The inter-pole voltage in conductors 1 and 4 opposes that generated by the main field pole, but that in conductors 2 and 3 augments the main field voltage by a like amount and the terminal voltage of generator is not affected.

With the brushes shifted in the direction of rotation to the position shown in Fig. 3, this balance is destroyed and the inter-pole voltage in all the conductors under the interpole operates with the main pole voltage, reducing the terminal voltage of the generator. Shifting the brushes against the direction of rotation augments the main pole flux and causes an increase in terminal voltage; were the machines shown by the diagram in Fig. 3 operated as motors in the direction indicated, the polarity of the inter-pole would be opposite that shown and the sine on the conductors would indicate the direction of the back voltage not the direction of current. It is obvious therefore that when the brushes on an inter-pole motor are shifted in the



Interpole Generator with Brushes off Neutral Point

Fig. 3

direction of rotation, back voltage will be augmented and the motor speed decreased. Conversely, shifting the brushes against direction of rotation increases the motor speed. A very slight shifting of the brushes from the neutral point, even as little as 1/16 of an inch on a machine of average size, may produce noticeable compounding effects. Compounding effects are sometimes purposely obtained by shifting the brushes off neutral which is a perfectly standard practice provided caution is used that they are not moved so far as to endanger commutation.

The parallel operation of generators is profoundly affected by brush position, and even when all other factors are adjusted properly, such as equalizers and field rheostats, the brush position must be exactly right in order that correct parallel operation be obtained, because the position of these brushes determines the compound characteristics — that is, the amount of voltage drop with increasing load.

Many serious cases of lack of proper parallel operation of generators have been cured by careful, judicious shifting of the brushes of the proper machine.

Our next article will discuss brush terminology and method of ordering brushes.

Wartime Developments In Compression Distillation

Commodore R. V. Kleinschmidt, USNR, who initiated large scale development of compression distillation at the research laboratories of Arthur D. Little, Inc.

Low fuel consumption in distillation has been made possible by the wartime development of the Kleinschmidt compression method. By this method, which essentially involves distillation by application of mechanical energy instead of external heat, an average of at least 175 pounds of distilled water may be obtained for each pound of fuel consumed; this ratio is three to four times greater than can be obtained with efficient conventional systems using fuel to generate heat. Although the compression principle has been known in theory for many years, it was first developed to the point of large scale use during World War II for the United States armed services.

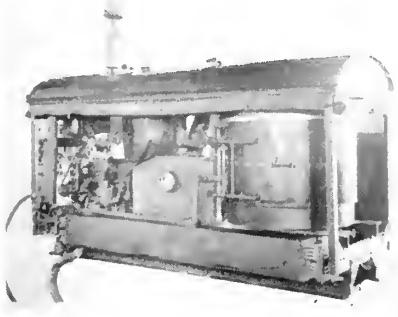
After several years of wartime secrecy, the principles of this method were described by Allen Latham, Jr., in a paper presented at the annual meeting of the American Society of Mechanical Engineers in New York. The Kleinschmidt compression distillation system was originally developed in the laboratories of Arthur D. Little, Inc., Cambridge, Mass., by a group headed by Dr. Robert V. Kleinschmidt, until Dec. 1, Commodore Kleinschmidt, U.S.N.R., but now again associated with Arthur D. Little, Inc. Mr. Latham, author of the ASME paper, directed wartime development of the system by Arthur D. Little, Inc., and its modification to fit a variety of practical needs.

During the war, E. B. Badger & Sons Co. of Boston, Mass., manufactured, under license from Arthur D. Little, Inc., Kleinschmidt stills for the U. S. armed forces. Many thousands of these stills were used aboard naval vessels—submarines, destroyer escorts and landing craft—to supply pure water from seawater. On land, several thousand gasoline-engine-driven portable units were used with great effectiveness, especially in the South Pacific, to supply our fighting men with water for drinking and other purposes where the sea was the only readily available source of water. By the end of the war there was enough Kleinschmidt compression distillation equipment in service to produce pure distilled water for the daily needs of over a million men.

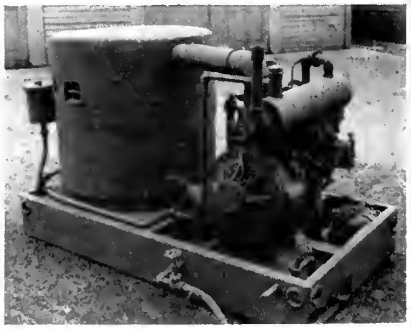
The value of this source of water to our forces is well indicated in Stf. Sgt. Jack Vincent's article in the October "Marine Corps Gazette" entitled, "Water on Iwo," quoted in part: " . . . Iwo was probably the most barren island ever invaded by such a large American force. There were no streams, and the few hot sulphur springs gave up water too brackish to drink . . . The Iwo Japs depended on rainfall for most, if not all, of their water . . . Reports that the Japs were desperate for water began reaching American lines as early as D + 10 . . . The Japs had nothing comparable to our mobile waterworks . . . " In Naval vessels, too, the high fuel economy of Kleinschmidt compression stills permitted many craft to make their water as needed rather than carry it as cargo, thus releasing space for fighting equipment and in some instances extending the vessels' cruising range markedly.

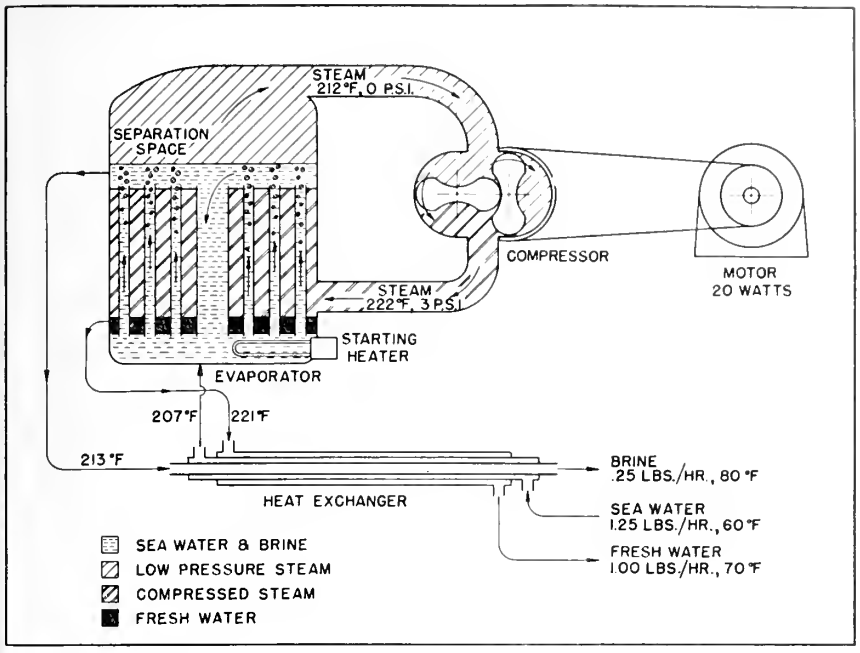
Compression distillation depends upon mechanically compressing the steam or other vapor leaving the evaporation compartment of the still. This compression raises the temperature of the steam a few degrees. At the higher pressure, the steam condenses at a temperature somewhat higher than the boiling point of the evaporating raw water, so that heat can flow from the condensing steam to the raw water and boil it. In engineering terms, the condensing vapor is used to supply heat inside the steam chest of the still in place of steam from sources outside the unit. Efficient provision for reducing heat loss to the atmosphere and recovering heat from the distillate and the concentrate carrying out waste as they cool down to room temperature completes the system. No separate condenser or cooling water is need-

The first gasoline-engine-driven compression distillation unit.



Recent Kleinschmidt compression distillation unit. This gasoline-driven model produces 1800 gallons of distilled water per day from sea water.





Diagrammatic representation of compression distillation as applied to the distillation of sea water.

ed. The over-all fuel economy of the most recent Kleinschmidt compression stills — averaging at least 175 pounds of distillate for each pound of fuel consumed—is believed to be the highest of any self-contained system of evaporation.

Technical Detail

After a compression still and its contents have come to operating temperature and the evaporator is filled with steam, the still may be turned on stream for continuous operation. In normal operation, for the production of fresh water from sea water, for example, the feed enters by way of a triple passage heat exchanger which heats the feed by extracting heat from both the outgoing distilled water and from the brine concentrate which carries out the solids of the sea water in a concentrated solution. The feed at about 207° F. is then introduced to the evaporator, where it mixes in a relatively large volume of brine which circulates naturally through vertical tubes. Steam from this boiling brine at, or slightly above, atmospheric pressure is led from the evaporation space through an entrainment separator to the compressor, which raises the pressure to about 3 lbs. per sq. in. gage, thus raising the temperature at which it condenses to about 222° F. Since the brine in the evaporation space boils at 213° F., there is a temperature differential of about 9° F. between the compressed steam and the boiling brine to permit transfer of heat from the former to the latter. Substantially all the latent heat, which is the heat given up by the compressed steam upon its condensation to water, is used in maintaining the necessary temperature level for continuous boiling in the evaporation space; thus no separate condenser or cooling water is required.

With a compression distillation unit of 1000 gallons per day capacity, the production of one pound of distilled water requires about 20 watt-hours or 68 BTU's energy input. A conventional single-effect evaporator requires about 300 watt-hours or 1020 BTU's per pound of distilled water. In multiple-effect evaporators the steam evaporating from the first "effect" is used, on condensing, to supply heat for the second effect, and so on up to three and occasionally four effects. The Kleinschmidt compression distillation system as applied to sea water distillation uses only one-fifteenth the energy of the single-effect evaporator and thus has an economy equivalent to some 15 or more effects, far more than could be practically operated. A compression distillation unit is far more simple to operate than a multiple-effect unit. The connections, heat transfer apparatus and controls are as simple as those on a single-effect evaporator. Ordinarily, control of the operation is made solely through adjustment of the flow of feed.

Compression distillation is now sufficiently advanced to justify its recognition as a major contribution to the techniques of distillation and evaporation. The Kleinschmidt still, by virtue of its low fuel consumption and its simplicity, shows promise in industrial applications of distillation and evaporation, both of water and other materials. With the wartime needs satisfied, the Kleinschmidt still will be manufactured under license for sale to industry.

Dutch Engine Room Telegraphs

Durkee*Marine Products Corporation of San Pedro, Calif., builds engine room telegraphs and voice tubing and accessories that have been selected for the 20 Dutch coasters now being built by the Albina Engine & Machine Works, Inc., Portland, Oregon.

The engine room telegraph transmitters and receivers are the Durkee* Marine standard single engine, single face, but the dials, marked in Dutch, are of special translucent porcelain.

The company has supplied a great many of the vessels built on the East and West Coasts, and the Gulf, with its well-known engine room telegraph systems.

All voice tubing accessories are of brass and bronze, with highly polished mouthpieces, and meet all governmental requirements.

Certified Alloy Valves

Certified Alloy Valve Company has been formed as a new division of The Cooper Alloy Foundry Co., Hillside, N. J. The new company will specialize in the manufacture of stainless steel valves for which it will furnish a certified analysis of every part which comes in contact with liquid. P. C. Shaffer is chief engineer. Products will be sold through Cooper.

This arrangement brings the entire metallurgical engineering and manufacturing process under one roof, including casting, heat-treating, machining and testing. The new division will have all the advantages of Cooper's more than 15 years' experience in the design and engineering application of many types of stainless steel valves and fittings.

NEW EQUIPMENT AND MACHINERY FOR YARD, SHIP AND DOCK

Ingalls Vessels Protected by "Magic Eye" Which Finds Smoke in Hold

It is natural that due to building ships of an all-steel construction we assume there is no need for fire-fighting equipment aboard them. But we have assumed incorrectly. For each ship built at the Ingalls Shipyard is equipped with one of the finest fire extinguishing and protective systems available. The system is not particularly for the protection of the ship as much as it is for the holds and the cargoes which are carried in them.

On every Ingalls-built ship fire hazards are cut to a minimum. Due to modern fire detecting and extinguishing methods, there is no danger of a fire smoldering for days undetected in cargo holds until it is beyond control.

One of these new fire detecting systems used on Ingalls ships is known as the C-O-Two and installed by the C-O-Two Fire Equipment Company of Newark, New Jersey. This system, like others used in Ingalls ships, is so accurate and sensitive that the indicator responds to the lighting of a match and the puff of a cigarette in the most remote section of any hold.

The C-O-Two smoke detecting system provides a means of detecting smoke automatically in any hold, an arrangement for visual indication of the exact location of the threatened space and an alarm to give audible warning the instant smoke appears. Cargo holds, bosun's stores, paint lockers and other spaces under comparatively infrequent surveillance of personnel are the sections most commonly assigned this kind of mechanical protection.

With the smoke detecting system, there is often combined a fire extinguishing system using carbon dioxide.

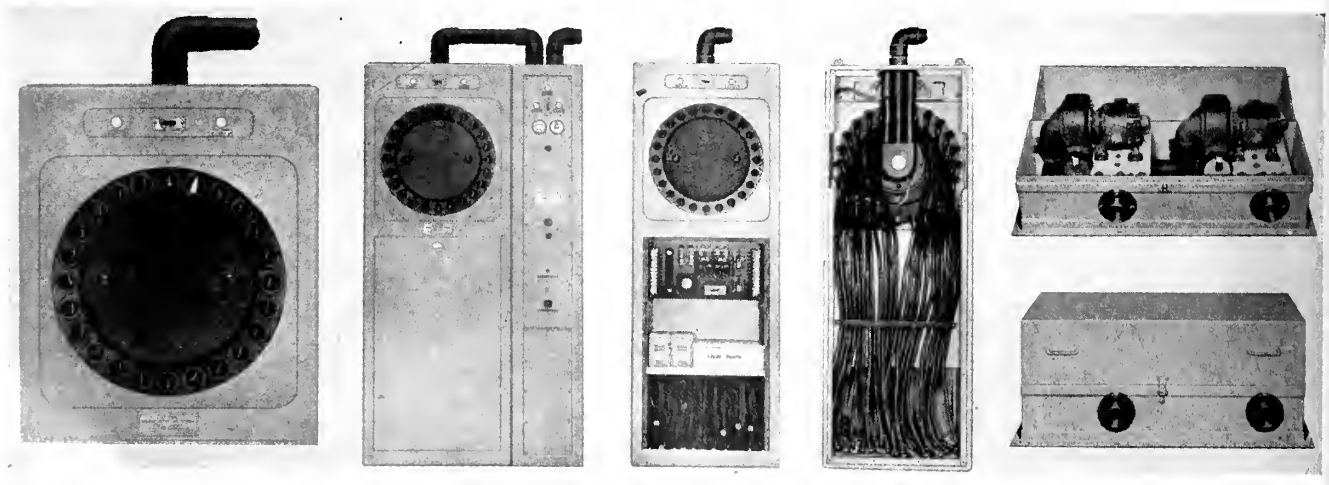
The nerve center of the smoke detecting system is the smoke detecting cabinet, in the wheelhouse, where it is under constant observation. One or more smoke accumulators are installed and located so that no overhead point lies outside a given radius from an accumulator.

A simple piping system connects the accumulators with the detecting cabinet. Duplicate electrically driven exhauster units, mounted on the deck above the wheel-house, continuously draw air samples from the accumulators through the piping system into the cabinet.

When a sample of air enters the cabinet it is conducted to a detecting chamber, with individual observation windows numbered to correspond with the protected spaces, where it is exposed to a considerable beam of light. If there is a trace of smoke in the air, it becomes immediately visible through one of the chamber's observation windows. The same smoke-bearing air, after leaving the window, is drawn through a photo-electrically controlled device, also in the cabinet, the operation of which instantly causes an audible alarm to sound. A chart near the cabinet identifies the spaces endangered.

The accumulators and piping of the detection system in the protected spaces can be utilized for discharging carbon dioxide when detecting and extinguishing functions are combined in a single system. A centrally located station containing three-way control valves and a battery of carbon dioxide cylinders are added to the system. The three-way valves make it possible to shut off the flow of sampling air to the smoke detecting cabinet and direct the flow of

C-O-Two smoke detecting system cabinets. Extreme left: Visual type. Arrangement of individual non-glare observation windows. Smoke is visible in observation window No. 13 and exact location of fire is instantly indicated. Second from left: Visual and audible type. Center: Visual type with front removed. Second from right: Visual type with back removed. Extreme right: Smoke detecting system blower box with duplicate blower units.



carbon dioxide from the cylinders to the space on fire.

The cylinders are released by local manual control for cargo protection. When the engine room is included in the extinguishing system, a remote manual control is used for this space. They are manifolded in sufficient quantity to provide "total flooding" of the largest space under protection on the ship. Cylinders may be arranged for discharge individually or collectively.

The fastest release of the discharge is achieved by systems equipped with two pilot or control cylinders and an arrangement which utilizes the carbon dioxide pressure from these two upon their being released manually, to actuate the discharge of the other cylinders in the bank. For "total flooding" installations, carbon dioxide pressure is used also to shut down ventilation, sound an alarm and close vents by means of pressure operated switches and trips.

Copies of the instruction chart posted near the smoke detecting cabinet, near the control valve station and at the cylinder location identify the protected spaces and likewise list the numbers of carbon dioxide cylinders recommended for the initial discharge and the number of cylinders subsequently to be discharged at specific intervals to insure complete control of fire in a particular compartment.

New Surface Preparation

The Amercoat Division of the American Pipe and Construction Co., P. O. Box 3428 Terminal Annex, Los Angeles 54, California, announces two new products supplementary to its line of Amercoat plastic coatings.

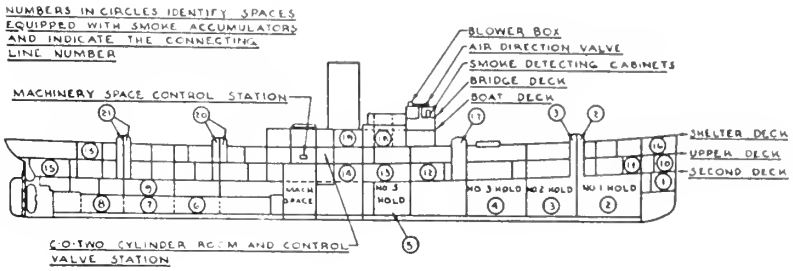
Amercoat No. 59—Surface Preparation for Zinc, is a treatment for galvanized metal surfaces prior to application of a protective coating.

Amercoat No. 60—Surface Preparation for Copper and Brass is a similar treatment for these metals.

These surface treatment solutions are for use where shot or sandblasting are impractical. The resulting adhesion of the protective coating is excellent where applied over a zinc, copper or brass surface properly prepared by these methods.

Printed application instructions are available upon request to the manufacturer.

C-O-TWO SMOKE DETECTING AND FIRE EXTINGUISHING SYSTEM



FOR FIRE IN MACHINERY SPACE

1. STOP BLOWERS, SHUT OFF FUEL OIL SUPPLY, AND CLOSE ALL DOORS AND HATCHES.
2. GO TO C-O-TWO CONTROL STATION FOR MACHINERY SPACE.
3. SOUND ALARM.
4. MAKE SURE THAT NO PERSONS ARE IN MACHINERY SPACE.
5. OPEN PULL BOX.
6. PULL HANDLE HARD-THIS SIMULTANEOUSLY RELEASES CARBON DIOXIDE FROM (27) CYLINDERS.
7. OPEN DIRECTION VALVE TO MACHINERY SPACE.

FOR FIRE IN CARGO SPACES

1. DETERMINE LOCATION OF FIRE-AFTER SMOKE IS SEEN IN AN OBSERVATION CHAMBER IN THE SMOKE DETECTING CABINET, NOTE LINE NUMBER AND REFER TO TABLE AND DIAGRAM OF SHIP TO DETERMINE NAME AND EXACT LOCATION OF FIRE. SILENCE ALARM GONGS.
2. MAKE SURE THAT NO PERSONS ARE IN SPACE ON FIRE.
3. CLOSE ALL OPENINGS AND STOP ALL VENTILATION TO SPACE BEFORE DISCHARGING CYLINDERS. THIS WILL CONFINE AND REDUCE LOSS OF CARBON DIOXIDE GAS AFTER IT HAS BEEN RELEASED INTO THE CARGO HOLD.
4. CLOSE THE AIR SHUT-OFF VALVE AND TURN THE CONTROL VALVE TO THE FIRE EXTINGUISHING POSITION FOR SPACE ON FIRE. VALVES ARE LOCATED AT THE MAIN CONTROL VALVE STATION.
5. RELEASE CARBON DIOXIDE GAS AT THE CYLINDER LOCATION FROM THE NUMBER OF CYLINDERS LISTED FOR THE INITIAL DISCHARGE OF GAS. CYLINDERS ARE ARRANGED TO DISCHARGE IN GROUPS OF TWO OR LESS. EACH GROUP IS NUMBERED WITH A NAME PLATE INDICATING THE TOTAL NUMBER OF CYLINDERS UP TO THAT POINT. THE FIRST TWO CYLINDERS ARE ARRANGED FOR INDIVIDUAL DISCHARGE. ONE CYLINDER OF EACH GROUP IS A CONTROL CYLINDER FITTED WITH A QUICK DETACHABLE COVER. DISCHARGE OF CONTROL CYLINDER SIMULTANEOUSLY DISCHARGES GAS FROM THE OTHER CYLINDERS IN THE GROUP. CYLINDERS SHOULD BE PROGRESSIVELY DISCHARGED IN GROUPS BEGINNING WITH THE LOWEST NUMBER TO PREVENT DISCHARGING MORE GROUPS OF CYLINDERS THAN DESIRED.

   TO DISCHARGE CYLINDERS - REMOVE QUICK DETACHABLE COVER AND STRIKE KNOB HARD.
6. MAINTAIN AN INERT FIRE EXTINGUISHING ATMOSPHERE IN SPACE ON FIRE BY DISCHARGING ADDITIONAL CARBON DIOXIDE GAS INTO SPACE AT INTERVALS. TO DETERMINE TIME BETWEEN DISCHARGES, CONSIDER THE DISTANCE FROM PORT WHERE A SUPPLY OF CARBON DIOXIDE CAN BE OBTAINED. DISCHARGES SHOULD BE MADE AT CLOSER INTERVALS WHEN SMOKE APPEARS TO INCREASE IN INTENSITY.
7. KEEP ALL OPENINGS IN SPACE ON FIRE SEALED WITH WET TARPAULINS AND ALL FANS STOPPED. HATCHES SHOULD NOT BE OPENED OR VENTILATION STARTED UNTIL ARRIVAL AT PORT. KEEP AIR SHUT-OFF VALVE CLOSED TO PREVENT FLOW OF AIR TO THE SMOKE DETECTING CABINET.
8. IF FIRE OCCURS IN TWO SPACES WHICH ARE LOCATED ONE ABOVE THE OTHER, FOLLOW INSTRUCTIONS FOR EACH SPACE AS GIVEN, BUT ALWAYS DISCHARGE CARBON DIOXIDE GAS INTO THE LOWER SPACE FIRST. THIS APPLIES TO BOTH THE INITIAL AND DELAYED DISCHARGES.

LINE NO.	SPACE	NUMBER OF CYLINDERS TO BE RELEASED FOR VARIOUS FILLING LEVELS OF HOLDS: HOLD FULL	HOLD ½ FULL	HOLD EMPTY

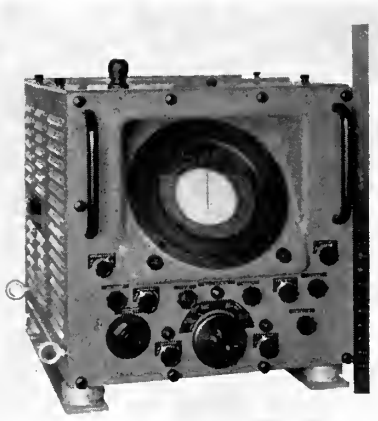
C-O-TWO FIRE EQUIPMENT COMPANY

NEWARK, NEW JERSEY



Unique Direction Finder Located Enemy Radar

American naval vessels easily located and identified Nazi and Jap radar installations through the use of an automatic radar direction finder. This ingenious electronic instrument, which was manufactured exclusively by the Submarine Signal Company, revolutionized the entire search technique for enemy radar sets. By means of its visual display of the direction finding information on a cathode ray tube, the operator could actually see the presence of the enemy installations.

Developed in the closest connection with the NDRC Division 15 Radio Research Laboratory set up at Harvard University, the Submarine Signal radar direction finder was one of the most versatile instruments that came out of the war. It measured the frequency of the intercepted signal as well as the direction from which it came, and was the only direction finder that could receive successfully the ultra-high frequency signals produced by the very latest radars.

This instrument is so sensitive that the experienced operator can look at the picture produced by the intercepted signals, tell what kind of radar had produced the signals and deduce the size and class of the ship sending these signals.

In the course of its first trial run aboard a destroyer escort the equipment clearly demonstrated its remarkable capabilities. During maneuvers offshore at night the radar operator of the DE made contact with a target at a certain range and bearing. The countermeasures operator, meanwhile, picked up a number of different signals all having the same bearing. From the characteristics of these signals, as well as from the frequencies at which they were tuned in, he deduced correctly that the vessel detected must have been a U. S. cruiser.

Oxweld-Unionmelt CM-37 Machine Carriage

A new heavy-duty, straight-line machine, known as the Oxweld-Unionmelt CM-37 machine carriage, has been developed by The Linde Air Products Company, Unit of Union Carbide and Carbon Corporation. It can be used for carrying Unionmelt electric welding equipment, the CMA-21-B attachment for plate-edge preparation, single- or multiple-blowpipe set-ups for straight-line cutting, flame-hardening equipment, and the Oxweld C-45 blowpipe for cutting extra-heavy sections.

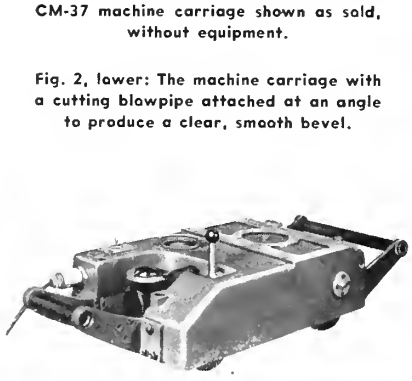
The use of high-strength aluminum alloys in the construction of the machine provides it with an ideal strength-weight ratio. Its weight as sold, without equipment (see illustration), is 87 pounds; thus it can be moved readily from job to job. Its over-all dimensions are 32 in. long, 12½ in. wide, and 9 in. high, plus 2⅞ in. for the forward-reverse lever.

The standard machine is equipped with a 110-volt a.c. unidirectional motor of ¼ rated electrical horsepower. Reversing is accomplished mechanically through gears. Machines are supplied with speed ranges of 2 to 50 in. per min. for general industrial use; and 7 to 210 in. per min. for use with the Unionmelt welding process. An electric speedometer is located in the machine cover so as to be within easy view of the operator at all times.

The CM-37 will operate on CM-21 track or, where accuracy of travel is not important, it can be operated on a standard 10 in., 25.4-lb. I-beam. It also can be operated directly on the steel plate or other flat workpiece, if desired.

Fig. 1, upper: The Oxweld-Unionmelt CM-37 machine carriage shown as sold, without equipment.

Fig. 2, lower: The machine carriage with a cutting blowpipe attached at an angle to produce a clear, smooth bevel.



Aer-A-Sol Insecticide Bomb

The Bridgeport Brass Aer-A-Sol insecticide bomb, containing a nonflammable formula developed by the U. S. Department of Agriculture, is an economical and effective new method for ridding commercial, public and private buildings, and also ships, of most types of insects. According to U. S. Public Health Service Supplement No. 183, the percentage of DDT is a desired concentration that offers no health hazard if used according to the maker's instructions.

Insecticide bomb in use, showing valve in open position.

The Bridgeport Brass Company, Bridgeport, Conn., made over 2 million insecticide bombs for the U. S. Navy during the war.

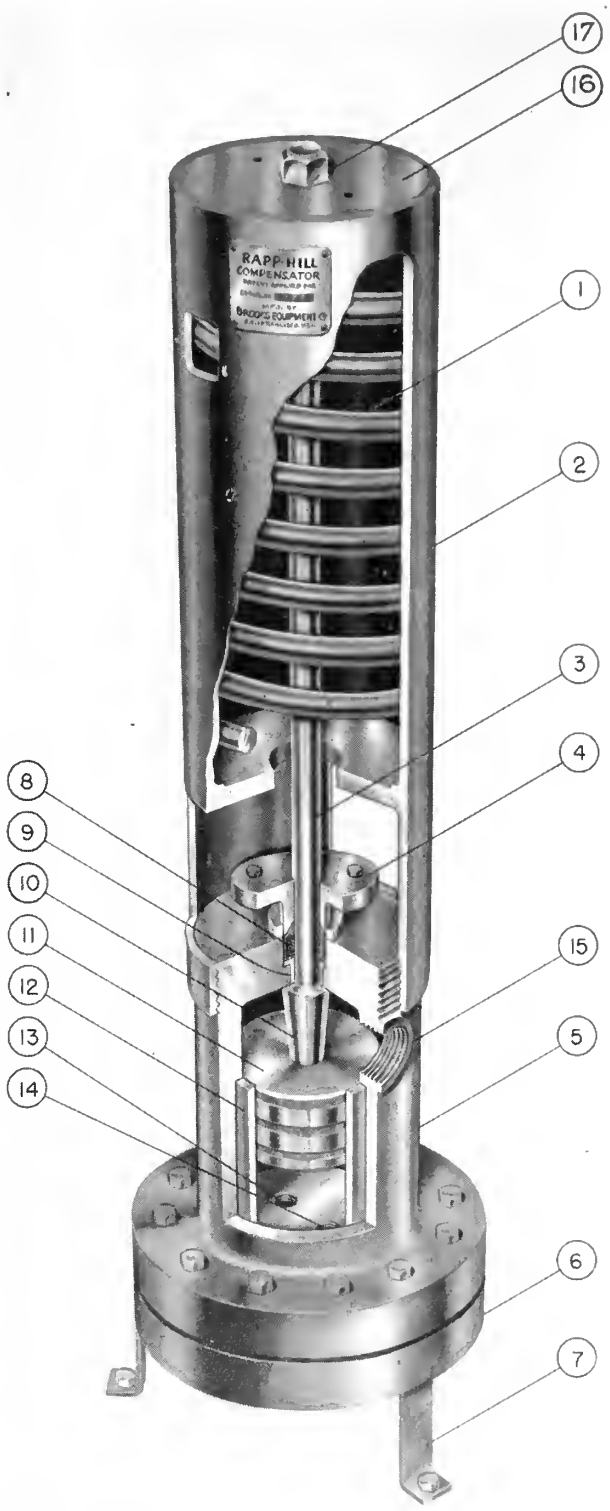
This bomb will be sold through the usual jobber supply and retail channels.

The Rapp-Hill Pump Compensator

The problem of excessive water hammering of the check valve in the feed water line, where a reciprocating type of feed water pump is installed, has for some time caused considerable concern to marine engineers, to the shipyard personnel and to the U. S. Maritime Commission. The noise, and particularly the vibration, resulting from this condition, which is due to the tendency of this type of pump to slam at the end of each stroke, puts an unnecessary load on the boiler economizers and tubes. In fact, according to information recently presented in a paper before the Society of Naval Architects and Marine Engineers in New York by D. S. Brierley, Director of the Division of Maintenance and Repair of the U. S. Maritime Commission in Washington, "prudent operating personnel on the vessels involved became aware of these unsatisfactory conditions very early, and as a result the majority of the vessels are now operating safely by utilizing the turbo - multo - stage feed pump for sea use, and retaining the reciprocating pumps for standby purposes."

About nine months ago two well-known San Francisco marine engineers, Walter B. Hill and Lawrence Rapp of C. C. Moore & Co., Engineers, became deeply interested in the problem. Rapp had the basic idea for the present design, which is a cylinder with water pressure on one side of the piston, steam pressure on the other side, and the unbalance taken care of by a spring. The advantage of this type of construction is such that the compensator will operate regardless of how boiler pressure varies, since the spring loading takes care of the unbalance between the feed water pressure and the steam pressure only.

On the first trial of the original idea, fitted on the S. S. Arcadia Victory, a single cylinder with a piston and a spring in the steam space was used, but the spring was found to be too weak. The strongest spring possible for the space available was then substituted, and very good operation was obtained up to about 15 double strokes per minute. Above this, however, the piston rod would hit the cylinder head, an indication that the spring was still too weak. In order to obtain heavier loading, and at the same time be able to vary the load-



1—Pressure Equalizing Spring, 2—Spring Guide Cylinder, 3—Piston Rod Externally Loaded, 4—Packing Gland, 5—Pressure Cylinder, 6—Pressure Cylinder Head, 7—Supports, 8—Hi-Pressure Packing, 9—Bushing, 10—Piston Stop, 11—Piston, 12—Monel Cylinder Liner, 13—Steam Inlet, 14—Drain, 15—Water Inlet, 16—Movable Spring Bearing and Adjustment Plate, 17—Lock Nut.

ing, a cylinder was built above the piston cylinder, in which was enclosed a spring of the required strength.

After many demonstrations on board a Victory ship, which were attended by the senior members of the engineering staffs of the various shipping companies, the U. S. Maritime Commission, the shipyards and the War Shipping Administration, the Final Guarantee Survey Board was favorably impressed with the results. In its report on the ship to Washington it included without solicitation the following:

"While aboard was inspecting the engine room. The operator was observing tests of the Rapp-Hill Main Reciprocating Feed Pump Compensator, and they observed the tests of the experimental unit installed on the water discharge of the after feed pump. As far as the observed demonstration of the apparatus is concerned the Board expressed the opinion that this equipment may possibly solve the problem of the excessive water hammer, which has prevented the installed reciprocating feed pumps being used as main feed pumps as originally intended. Refer to Engineer Plan Approval."

The apparatus shown in the adjoining pictorial drawing operates as follows:

(1) Desuperheated steam at full boiler working pressure enters the bottom of the cylinder at (13).

(2) Water from the discharge of the pump enters the upper part of the cylinder at (15).

(3) Top plate (16) and screw (17) are used for making any necessary adjustments on spring (1), which takes care of any unbalance or differential in pressure between steam and water in the lower cylinder.

(4) As the feed water pressure increases during the pump stroke, the piston (11) moves down, compressing the spring (1) until balance is achieved.

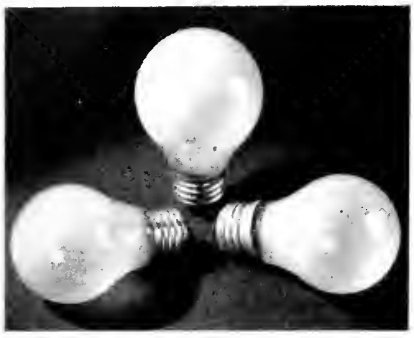
(5) As the feed pressure decreases at the end of the pump stroke, the piston (11) moves upward, unloading the spring feeding water back into the feed line through (15).

The discharge pressure from Simplex Feed Pumps on Victory ships varies from 55 psi to 250 psi, but with the use of the Rapp-Hill Compensator it goes from 500 psi to 450 psi minimum, thereby eliminating the extreme variation in pressure, and consequently the disturbing noise and vibration.

The Rapp-Hill Pump Compensator is manufactured and distributed by the Brooks Equipment Co. of California, 636 Potrero Avenue, San Francisco, Calif.

Low Voltage Incandescent Lamps for 6, 12 and 30 Volt Service

Low voltage inside frosted lamps in standard bulb sizes with medium bases and rated at 1000 hours' life are now available from Sylvania Electric Products Inc., Salem, Mass. Six



and twelve volt lamps in 15, 25 and 50 watt sizes are designed specially for battery-generator sets used in small boats, camps, farm lighting, Windcharger equipments, buses, small planes and portable battery-operated lighting. Used with standard extension cords, six volt lamps make a handy trouble light which may be operated anywhere directly from an automobile battery. Thirty volt lamps in 15, 25, 50 and 100 watt sizes are designed for use with battery-generator circuits averaging between 28 and 32 volts used on large farms, railway cars, tug and workboats and medium sized commercial planes.

Hydraulic Governors Service Stations

The Marquette Metal Products Company has originated a unique service to users of its hydraulic governors in establishing service stations in strategic locations, making it possible for Government agencies and commercial vessel operators to get prompt, dependable servicing of governors.

The service stations are conveniently located at 4512 San Pablo Avenue, Emeryville, California; 835 Howard Avenue, New Orleans; and 47-49 Wooster Street, New York. The stations are devoted to service only. All matters pertaining to sales are directed from the company's home office at 1145 Galenwood Drive, Cleveland, Ohio.

Interior view of the Marquette Governor Service and Training Station, New York shop. Similar shops are in New Orleans, Los Angeles and Emeryville, California. At the right a reconditioned governor is being tested on a diesel engine.

"Bean Soup" Smothers Fires

Resembling luscious whipped cream, the Navy's fire-fighting "bean soup" smothers even the toughest fires at sea or ashore with a thick blanket of foam derived from mixing a special liquid made from soy beans with water and air. A five-gallon can of liquid produces nearly 900 gallons of airfoam in a few seconds to form a tough, gas-tight blanket which cuts off oxygen and snuffs out flames. Airfoam (as shown) flows freely, yet sticks to vertical surfaces as well as flat areas. And while the Navy's traditional beans are far more nutritious, this "bean soup" looks more appealing — and spells safety. National Foam System, Philadelphia, has just processed its 4,000,000th gallon of the basic liquid, known technically as Aer-o-foam. It is particularly effective in combating petroleum and chemical fires.

Oil Conditioners Make Big Saving

An estimated saving of 44 thousand dollars per year in the operation of 14 large cranes through the successful adoption of revolutionary oil conditioning practices is shown by records from the files of a well-known engineer in charge of mechanical equipment at one of the big West Coast shipyards.

Oil consumption was cut from approximately 18,000 gallons per year down to approximately 6000 gallons, and the full-time labor of five men was saved through the use of lubricating oil conditions designed and built by the Winslow Engineering Company.

Other benefits include the fact that the 200-horsepower Cummins and Buda diesels which power the cranes are now showing a remarkable degree of efficiency by operating without overhaul for periods of 16,000 hours or more. Previously, overhaul schedules called for "time down" every 10,000 hours or less.

Troubled by the fact that a five-man crew was required on a full-time basis merely to change the oil in the engines of the 14 cranes every 150 hours, and that waste oil was disposed of at the rate of 1000 gallons per month, this engineer installed high capacity industrial and marine type Winslow oil conditioners on a test group of four of the cranes. Results immediately justified similar installations on the remaining cranes.

Now oil is changed only after 500 to 650 hours of operation on each of the engines. Filter elements are changed at this time, but flushing oil, which was previously used, is no longer necessary. Waste oil disposal has dropped from approximately 1000 gallons per month to an average of about 166 gallons per month, a cut of 83 per cent, at an estimated saving of about $6000 per year.

Oil changes are now handled by the men who clean and oil the cranes while the cranes are tied up. Estimated labor cost savings amount to about $38,508 per year. Added to oil savings, this comes to $44,508 per year. Against this alone, Winslow oil conditioner installation costs are considered negligible.

Estimated time and dollar savings do not include the man-hours and equipment time previously lost every 150 hours when operators and slingers had to stand by during oil changes. Figures are based on 24-hour-per-day operations.

Each of the oil conditioning units consists of a steel cylindrical container which encloses seven replaceable sock-type filter elements. The Winslow Engineering Company of Oakland, California, has designed and built this type of conditioner to provide sufficient capacity to accommodate the full flow of oil, so that only filtered oil reaches the bearings. Larger as well as smaller units to meet specific oil flow requirements have long been in successful operation in many industrial as well as marine applications throughout the country.

Gas Detection and Analysis Instruments

The Davis Emergency Equipment Co., Inc., Newark, N. J., announces an extended line of gas detection and gas analysis instruments. The new line will include the company's combustible gas alarm systems, along with safety equipment for the detection and analysis of combustible gas or vapor in air.

It will also detect and analyze any one gas, whether combined or not with other gases. All of the instruments will be available with a variety of chart recorders.

On the Ways — SHIPS IN THE MAKING

LCM's ON RE-ASSEMBLY LINE

Hulls of LCM's. Some of 52 landing craft built on the Pacific Coast, cut into sections there and sent East on freight cars for re-assembly, take shape once more alongside big tanker in drydock at Todd Shipyards Corporation's Brooklyn division. Believed the first project of its kind, the craft were shipped in parts across continent when Navy decided to use them for amphibious training in Florida.

Europa at Todd Yard For Repair

The 49,730-ton former Hapag-Lloyd liner Europa, which was seized from Germany by the Allies in Bremerhaven last May 8 and put into service as a United States Navy troop transport, went into the Hoboken division of Todd Shipyards Corporation for extensive voyage repairs, after making three trips with troops to New York. The Europa is the largest vessel ever to be repaired in the Todd Hoboken yard, and is probably the largest ship that ever entered any private American repair yard.

The Europa (AP-177), as the Navy knows her, had lain at her pier in Bremerhaven since soon after the outbreak of the war in 1939, and not all of the ailments of long disuse were straightened out when she was partially converted to a Navy transport and arrived in America on her first trip under the American flag, with a Navy skipper, on September 25.

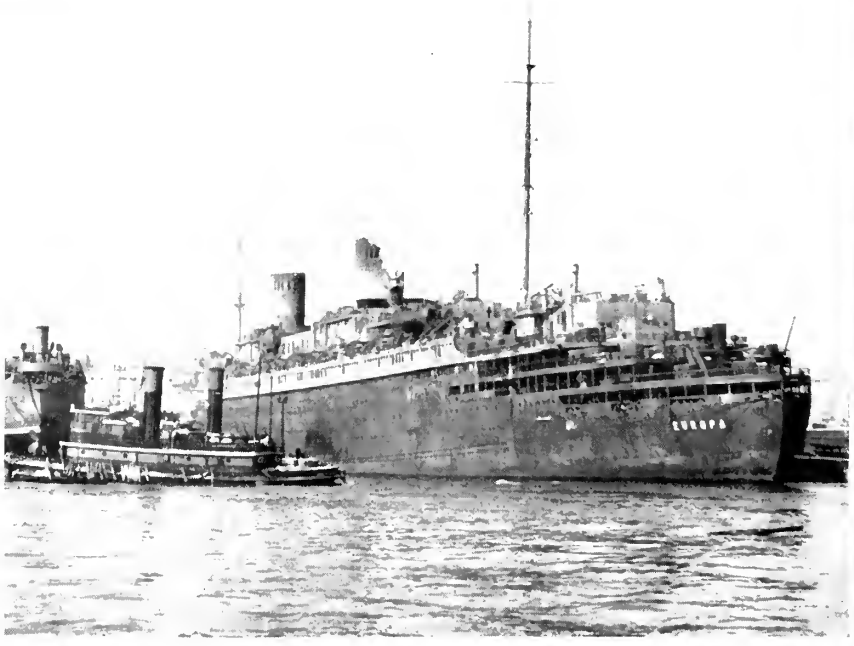
On September 27, the Europa went to the Navy Yard Annex in Bayonne, N. J. It had been planned to make a complete conversion of the vessel, in 45 days, into a transport capable of carrying more than 10,000 men. Because of the immediate need of her services, however, it was decided not to perform the full conversion.

The ship presents a wide variety of repair problems.

They Get Around

A 100,000 mile voyage that included seven crossings of the International Date Line and eight crossings of the Equator was revealed recently when the log of the Socony-Vacuum Oil Company tanker SS Mobiloil was examined.

The tanker, skippered by R. C. Doull, Master, traveled through the Suez and Panama Canals, around the Cape of Good Hope and Cape Horn and in the waters of the Atlantic, Pacific, Antarctic regions and Indian Ocean as well as the Gulf of Mexico, Persian Gulf, Gulf of Aden, Gulf of Oman, the Arabian, Red, Tasman and Caribbean Seas.



Europa, former Hapog-Lloyd liner, arrives at Hoboken division of Todd for repairs, after making three trips with troops.

The Month's West Coast Shipbuilding Record

West Coast shipyards delivered 16 vessels, or 38.3 per cent of those turned out in the United States during the month of November, according to figures released by the U. S. Maritime Commission. West Coast tonnage delivered totaled 127,699 deadweight tons. Atlantic Coast shipyards delivered 10 vessels and Gulf yards 15 ships.

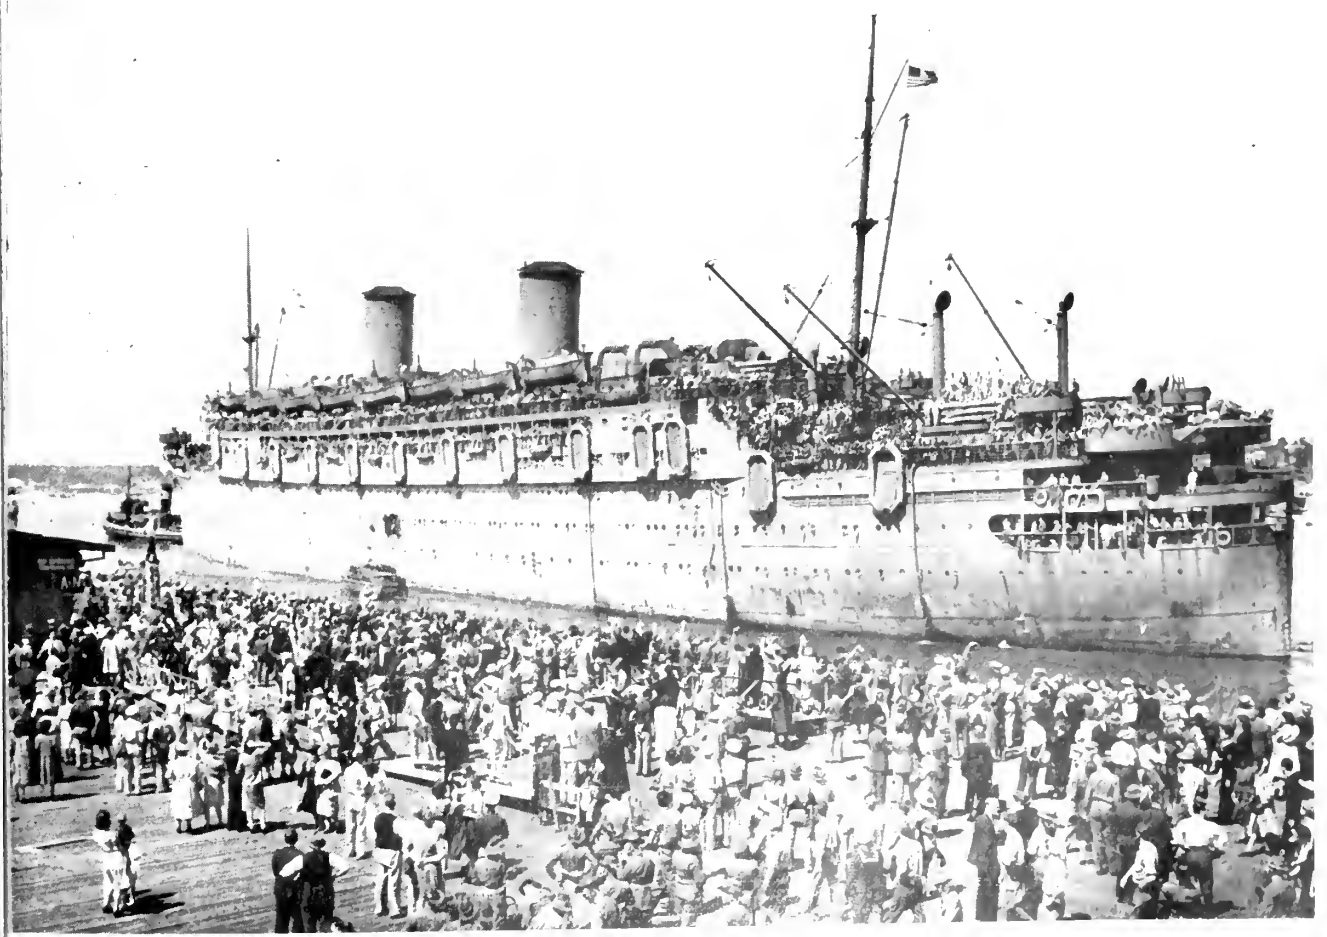
The Albina Engine & Machine Work of Portland delivered 3 coastal cargo ships, and the Oregon Shipbuilding Corporation 5 Victory cargo carriers. The Kaiser Company yard at Swan Island delivered 2 T2 tankers and the Kaiser Vancouver Yard one C-4 Transport for the Army. In Wilmington, California, the Consolidated Steel Corporation delivered 4 coastal cargo carriers.

Of the 42 ships delivered from the United States shipyards in November, 5 were Victory cargo carriers, 7 C-type cargo ships, 16 coastal cargo carriers, 2 private coastal cargo carriers, 5 standard tankers, two transports and 5 coastal tankers.

MATSON SHIPS DURING WAR

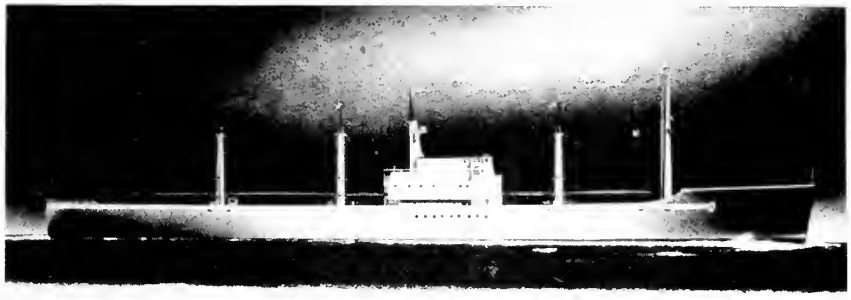
Above: Home Again! SS Mariposa disembarking troops at Port of Boston.

Below: The SS Lurline leaving the dock of Brisbane on September 11, 1945. This was the first Matson liner to leave an Australian port since the cessation of hostilities. The former luxury liner was booked to capacity, carrying a grand total of 3560 persons bound for San Francisco. This voyage of the SS Lurline was known as the "War Bride Voyage," as there were over 500 wives and over 200 children aboard.



Above: Commander Carvalho (center) is shown with, left to right, J. H. Morris, assistant machinery superintendent; R. I. Ingalls, Jr., vice chairman; A. M. Swigert, works suprintendent, and Pierce Archer, Ingalls' representative at Rio.

Below: A model of 12,000-ton cargo ship built for Brazil.



Ships Built for Brazil

Note: These ships were featured in several recent issues of Pacific Marine Review.

All fourteen 12,000-ton cargo ships being built for the Brazilian government by the Ingalls Shipbuilding Corporation at Pascagoula, Miss., at a cost of $37,000,000, are being equipped with Hagan automatic combustion control, according to J. M. Hopwood, president of Hagan Corporation.

Brazil, it was learned, is building a total of 24 cargo ships, at a cost of $54,000,000. The remaining ten are being built in Canadian yards. The ships are being built for the Brazilian government through its agent, Lloyd Brasileiro.

Hagan Corporation pioneered in designing systems for automatic fuel-air proportioning for industrial boiler plants and for utilities power plants in the latter days of World War I. It designed the first combustion control system ever put aboard ship when the Standard Oil tanker R. P. Resor was so equipped in January, 1936.

New Barge for Tracy Fleet

The Cape Low, first of four new 142-foot hopper barges for M. & J. Tracy Company of New York, was launched recently at the Wilmington, Delaware, yards of Dravo Corporation.

NEW BARGE FOR TRACY FLEET LAUNCHED

The sponsor's party: D. R. Berg, admin. manager of Wilmington Yard, Dravo Corp.; A. A. Low, vice president of Consolidated Edison Company of New York; H. S. Sutton, exec. asst. to the president, Consolidated Edison; Mrs. A. A. Low, sponsor; W. J. Lane, superintendent of construction, M. & J. Tracy, Inc.; Mrs. William J. Tracy; J. A. Lennon, secretary of M. & J. Tracy, Inc.; W. J. Tracy, president; H. C. Dean, executive vice president of New York and Queens Electric Light and Power; Warren Brewer, asst. admin. mgr., Dravo Wilmington yard; R. E. Dennis, fuel agent Consolidated Edison; and J. H. Murray, superintendent of floating equipment B & O Railroad.

Brazilian Visits Ingalls Yard

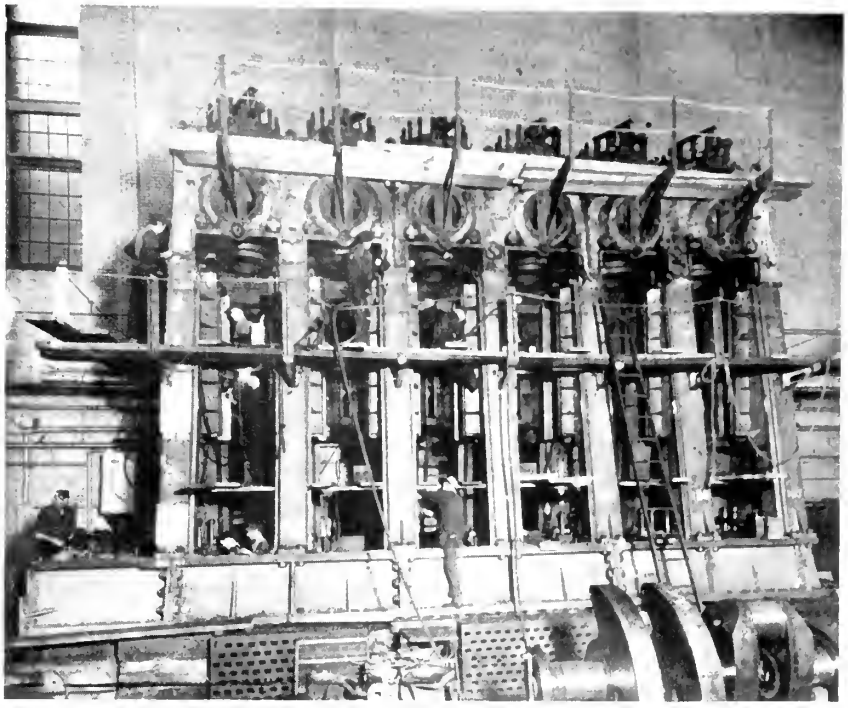
Commander Enrico Magno de Carvalho, of Rio de Janeiro, special representative of the Brazilian minister of transportation and public works, recently inspected the Ingalls Shipbuilding Corporation yards at Pascagoula, Miss. Commander Carvalho, of the Brazilian Navy, is connected with SNAPP (Service De Navegacao Da Amazonia E De Administracao Do Porto Do Para) as a marine engineer and naval architect. The organization is in charge of developing 3400 miles of river transportation along the Amazon. The Ingalls yard, with a backlog of $120,000,000, is building 14 modern cargo ships at a cost of $37,000,000 for the Brazilian-owned Lloyd Brasileiro Lines.

First Visit to U.S.A. of New Swedish Motorship

The newly-commissioned Johnson Line motorship Biobio, one of the most luxurious combination, fast passenger and cargo carriers ever assigned to this trade under the Swedish flag, was dispatched from Gothenburg on November 28. She is due to arrive in Seattle, Portland, San Francisco, Los Angeles and British Columbia ports around the end of December, with a full cargo of Swedish paper and pulp, as well as other Scandinavian products.

Delivered to her owners on November 12, the Biobio is the second modern motorship assigned by the Johnson Line for the resumption of their post-war European-Pacific Coast passenger, refrigeration and freight service.

Pacific Coast agents W. R. Grace & Co. state that the motorship has spacious accommodations for 30 passengers, as well as features that combine the most modern shipbuilding ingenuity in handling all varieties of fresh, dried and canned fruits and fish.



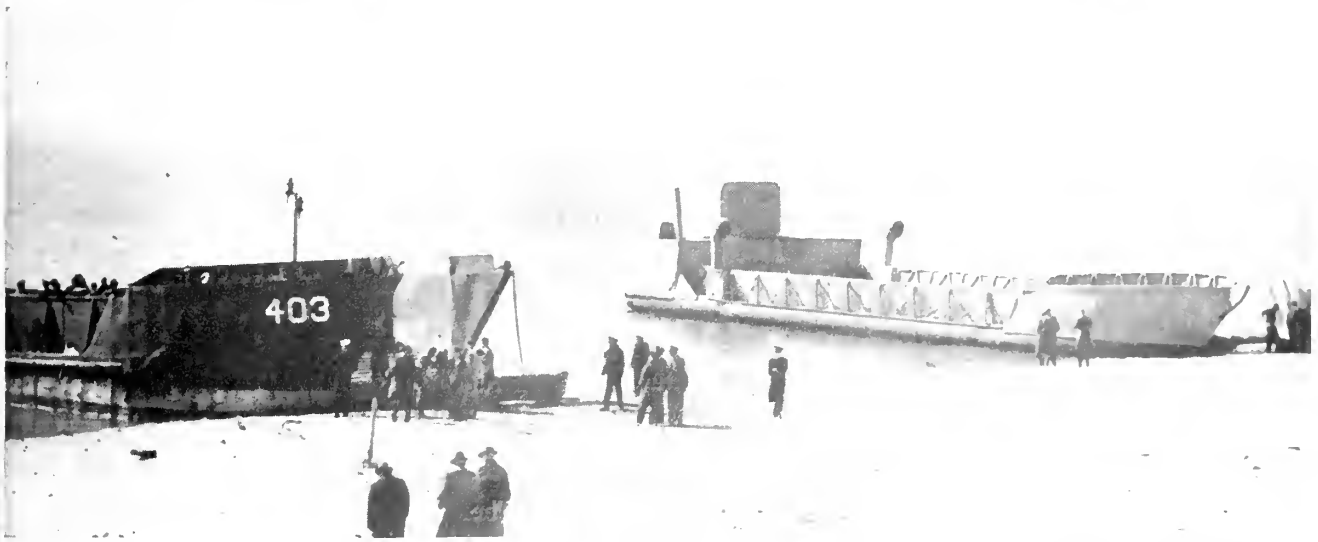
200-TON KRUPP DIESEL ENGINE REBUILT IN U. S. A.

One of the biggest jobs of its type in this country, Bethlehem Steel's Staten Island shipyard rebuilt this 200-ton Krupp diesel. It was removed section by section from the 10,871-ton tanker M. S. Peter Hurll. After repairs, which included installation of four new 20-ton bed plates and 14 fabricated steel housings of new design, the motor was again disassembled and replaced in the tanker.

Chinese Get 10 Coastal Cargo Steamers

The Chinese Supply Commission was awarded 10 coastal cargo vessels of the N3 type by the United States Maritime Commission. The bids ranged from $410,000 to $451,000 for each of the vessels. The Supply Commission was the only bidder submitting sealed bids at the opening held Wednesday, December 19, 1945. The freighters, 258 feet long and of 2,750 deadweight tons, were built in 1944-45. All of the vessels are now at Los Angeles, California, with the exception of one at San Francisco.

LAUNCHING A DECOY RUBBER LANDING CRAFT



This collapsible pneumatic rubber craft, made by United States Rubber Company, was part of the "ghost army" developed and operated by Army Engineers to fool the Germans in important European operations. The decoys were easy to send to combat areas because they were collapsible, packed compactly, could be inflated quickly in the field and deflated easily for moving to a new location.

STEADY AS YOU GO

(Continued from page 64)

these minutes are further divided into **tenths of minutes,** or **six seconds.**

(3) **The Horizon Glass.** This is rigidly fixed to the frame perpendicular to the plane of the instrument and parallel to the index mirror when the index arm is set at zero. The horizon glass is fixed in a metal frame and one half (the half farthest away from the instrument frame) is plain glass and therefore transparent, so that objects may be seen directly through it by the telescope; while the other half (the lower half near the frame) is a silvered reflector or mirror. This mirror receives the rays of the object reflected from the index mirror and transmits them to the observer through the telescope. The horizon glass is fitted with two small, capped adjusting screws so that the horizon glass can be kept perpendicular to the plane of the instrument.

(4) Horizon shades of colored glass (usually three) of different densities and different colors are fitted so that they may be turned up as required beyond the transparent part of the horizon glass to tone down excessive glare on the horizon of the direct rays of the sun.

(To be continued)

Radio Direction Finder

Fishing craft owners, yachtsmen and navigators of almost any vessel will be interested to learn that the very compact and trustworthy "Turret" radio direction finder is again available to other than Government users.

The Paulsen-Webber Cordage Corporation manufactures this instrument in its Marine Electronics Division, and maintains in the current model the features that made the set so popular during the 1930's. The space occupied is small enough to give it a place in the smallest chart room or wheel house. It is completely self-contained, and avoids all battery troubles by operating directly from any standard marine lighting circuit.

Its efficiency ranks with that of direction finders selling for as much as four times the price, yet its mechanism and electrical circuits are so worked out as to eliminate the complexity of knobs which often slows down the taking of bearings with other sets. This simplicity, plus a rugged construction, reduces service needs to a point where years frequently elapse before any technical attention is needed.

A characteristic of the "Turret" direction finder is the dial on the front of the instrument, from which bearings are taken in the compass points or degrees around the outline of the ship—where no part of the card is obscured and where both light and line of vision contribute to accurate navigation.

A Plastic Sealer Compound

A material for filling or sealing ends of pipes or tubes through which electric cables are strung has been developed by The Dolphin Paint & Varnish Company, Toledo, Ohio, and is known as No. 3984-3 Dolfinite Plastic Sealer Compound.

It has sufficient stiffness to hold cables away from the steel tubing, and is used mainly on U. S. Navy and Coast Guard ships. It has the consistency of putty and remains plastic so that cables may be easily removed when replacement or repairs are necessary. Generally applied by hand or with ordinary putty knife, it is waterproof and unaffected by either heat or cold.

It conforms to Navy Department Specification 17-1-15, meeting all the requirements of Type H (Heat Resistant) for use when cables are located on decks or weather exposed surfaces requiring water and weather resistance, and Type HF (Heat and Flame Resistant) for application in engine, boiler rooms and hot places.

Los Angeles Propeller Meeting Honors the Marine Exchange

Program Chairman Leonard Backus gets facts and figures on operations of newly reopened Marine Exchange lookout station at San Pedro. Left to right: Hugh Middleton; Gus Grom, assistant manager of Marine Exchange; Leonard Backus; and A. L. Allyn.

The Marine Exchange at Los Angeles Harbor is in full swing again, after a four-year silent period, back on the job of reporting ship movements about the port to shipping and related agencies. The Exchange is under operation by the Los Angeles Chamber of Commerce, under **Howard W. Woodruff**, manager. Woodruff is well known around the Port and with the Propeller Club activities in Southern California.

At the lookout station atop Warehouse No. 1 at San Pedro, **Gus Gram** is in charge of a staff of six, most of

them veterans of the Exchange. "Old timers" at the station besides Gram are: Al England, Ross O'Laughlin, Bill King and John O'Donnell; and two experienced former Navy signalmen, Leo Riley and Kenneth Moore, have been added.

The guest speaker on the program for the December meeting of the Los Angeles Propeller Club was Sky Pilot James Whitcomb Brougher, Jr., whose remarks on his experiences during the war operations were entertaining as well as enlightening.

ELECTION of Wilson H. Moriarty, vice president in charge of sales of National Malleable & Steel Castings Co., was announced by President Charles H. McCrea. Mr. Moriarty has been assistant to president.

Scenes from Joslyn-Ryan Holiday Banquet

At right: Michael Ryan and Paul Joslyn at annual Christmas banquet.

Center: During the program Paul Joslyn and Mike Ryan were each presented with a beautiful leather brief case as token of appreciation from office staff.

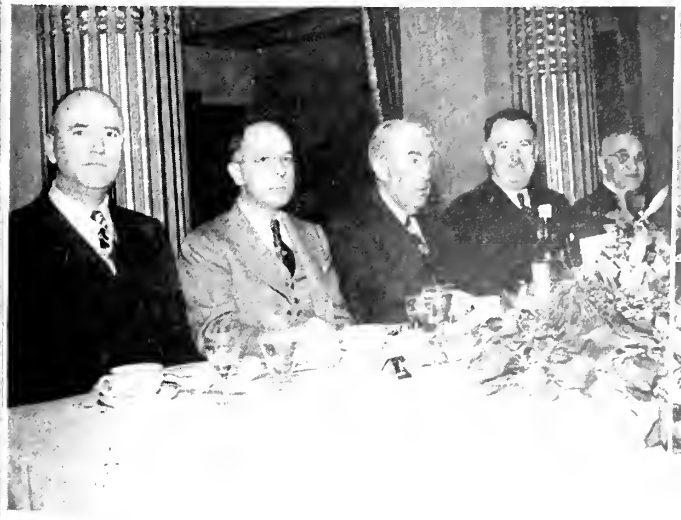
Joslyn-Ryan Observe Yule Season

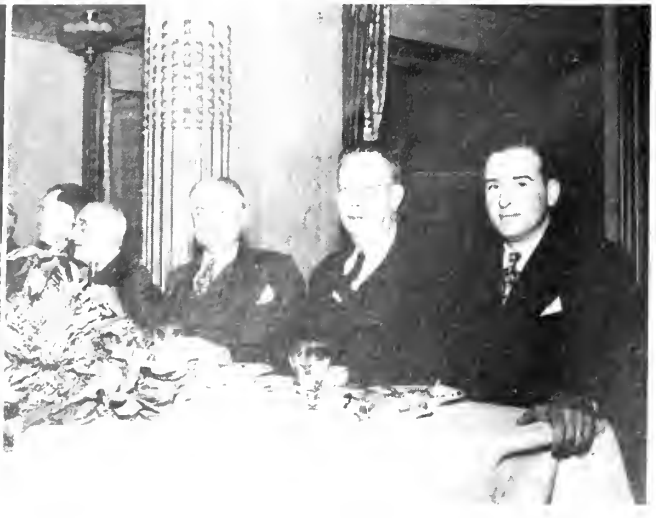
The staff of Joslyn and Ryan of San Francisco, naval architects and marine engineers, held their annual Xmas party on December 21 in the Colonial Ballroom of the St. Francis Hotel.

There was an attendance of over two hundred staff members and a very creditable program of entertainment was provided by the talented members of the party.

All arrangements were well handled by a committee under the guidance of Charles King.

Accompanying Paul Joslyn and Michael Ryan at the speakers' table were the following gentlemen: Roger Murray, Fairbanks, Morse Co.; E. S. Schulters, U.S.M.C.; Sheriff Daniel Murphy of San Francisco; Thomas S. Meehan, the Cracker National Bank; Carl W. Flesher, Joshua Hendy Co.; Charles M. Laring, Supervisar's Office, U. S. Navy; and Leslie L. White, Matsan Navigation Company; Jack Radford, Fairbanks, Morse.





Yule Season Feted At Groves Party

Top, right: Jovial twosome, seated, is C. T. Solomon, port engineer, General Steamship Corp., Ltd., and reaching for high C is J. F. "Joe" Gisler, port engineer, Interoceon Steamship Co.

The Frank Groves Company of San Francisco held its annual Holiday party for port engineers and steamship company officials at El Jardin Restaurant on December 15. Almost two hundred guests were in attendance for the dinner party and entertainment.

SHORESIDE PERSONALITIES

COMMANDER JOHN R. PAGE has been loaned by General Steamship Corporation to the UMA in London to act as assistant to Ernest J. Bradley, United States UMA representative in that city. Page recently returned to General Steam, after his discharge from the Navy, as manager of its European department.

CHIEF OF ECLIPSE DIVISION, BENDIX, is Frank T. Christian. He was appointed chief engineer of the Eclipse Machine division of Bendix Aviation Corporation. Mr. Christian has been associated with the staff since 1929. During the last five years he has directed engineering for the company's commercial production of Bendix starter drives and bicycle coaster brakes.

MANAGERS OF FRANK GROVES COMPANY

Left to right: Ed Thirkell, manager of Portland Branch; Frank Graves, president and general manager; and H. T. Waldron, manager of San Francisco Branch.

HARRY A. BURDORF, vice president in charge of Sales for the Lunkenheimer Company, recently visited the Pacific Coast offices and the distributors of the firm. This was his first trip to the Coast since 1939.

Edward H. Johnson is now in charge of Sales for the company in the Northern California and San Francisco Bay Areas. Republic Supply Company of California, who have distributed the Lunkenheimer products for many years in Southern California, was appointed distributor for Northern California with headquarters in Emeryville. Robert Temple is the manager.

John Eldridge Cushing

COMMANDER HARRY A. SHAWK, back after four years and 10 months on active duty with the Navy, has assumed his old duties with The Tide Water Associated Oil Company of San Francisco, as consulting engineer and supervisor of Marine Sales. During the war he was commanding officer, U. S. Naval Section Base, Humboldt Bay, and Section Commander of Northern California Sector, Eureka and Monterey.

THE SANTA FE RAILWAY'S San Francisco ferry service recently announced the retirement from active duty of Captain Wilfred John Osborn, who entered the service as a first officer in 1910 and served as captain since 1911.

CUSHING AND LAPHAM BACK AT AMERICAN-HAWAIIAN

The turn of the year saw John E. Cushing (at left) back as president of American - Hawaiian Steamship Company, after spending the war years on leave to the War Shipping Administration, as Deputy Administrator for the Pacific Coast.

In a new position at American - Hawaiian is Lewis A. Lapham, Jr. (at right), who became assistant to President Cushing.

THE POSITION LEFT VACANT by the resignation of John E. Cushing as Assistant Deputy Administrator of the War Shipping Administration has been filled by Felix Isherwood, who has held the post of special assistant to Mr. Cushing. Isherwood will take charge of the War Shipping Administration offices in the Pacific Ocean area.

THE GRACE LINE announces the appointment of Captain Roy A. Steimer as Master of the SS Pierre La Clede and Robert R. Spurling as chief engineer of the SS Cape Gaspe.

ELLINWOOD INDUSTRIES, Los Angeles, manufacturers of farm, marine, home and office equipment, have added five new executives to the staff. According to President Ray Ellinwood, **Orrin Broberg** is chief engineer of the marine equipment division; **Colin Chambers** is sales manager of furnace brazing and heat treating; **D. W. Morgeson** is superintendent of the farm equipment division; **Palmer Wentworth** is personnel manager, and **John H. Williams** is project engineer with the farm equipment division.

RAY W. TRUMBULL, president, Edison General Electric (Hotpoint) Appliance Co. was elected vice president of National Electrical Manufacturers Association in New York. He is a member of the board of governors of the association.

M. G. Gamble, who succeeded B. B. Howard as general manager of Marine Operations.

Esso's Marine Management Appointments

M. G. Gamble, widely known marine and shipping authority, is now general manager of marine operations for Standard Oil of New Jersey. He succeeds B. B. Howard, recently elected to the board of directors.

As assistant general manager during the war, Mr. Gamble was active in coordinating the operations of the Esso tanker fleet under the WSA.

John J. Winterbottom, manager of the marine traffic division, until recently on leave with the WSA, is assistant general manager, and E. H. Le Tourneau continues as assistant general manager.

B. B. Howard, who has been with Standard Oil Company (New Jersey) since 1920, is now an Esso director.

J. J. Winterbottom is new manager of the marine traffic division.

Mr. Gamble, a native of Louisville, Georgia, left the Navy to join the construction and repair division of Esso's marine division after the first World War. An Annapolis graduate, he had served during the war years in both engine and deck officer duties. In 1937, as assistant in the traffic division, he handled marine affairs in Venezuela and lake tanker shipments in Caribbean ports. The following year he became manager of the newly created Caribbean division, and in 1939 went to Aruba as marine manager directing activities in Venezuela and the Caribbean. He was appointed assistant general manager in New York in 1942.

E. H. Le Tourneau, who served as a Navy Lieutenant in World War I, joined the company in 1921. He entered the repair division, later became assistant manager of construction and repair, and then manager of the repair division. Appointed acting assistant general manager of the marine department in May, 1943, he succeeded the late H. J. Esselborn as an assistant manager the following March.

John J. Winterbottom entered the foreign shipping department of Jersey Standard in 1916. In 1930 he went to London as adviser to marine managements of European subsidiaries. He was made manager of the traffic division in 1940. Back from his WSA job, he has taken up duties as assistant general manager.

The election of Bushrod B. Howard to the board of directors of Esso on August 31, makes him the eleventh director, following the retirement of Wallace E. Pratt. Mr. Howard is widely known in the shipping world, having been associated with Jersey's large tanker fleet since he joined the company in 1920. He has been general manager of the marine group throughout the war period.

E. H. LeTourneau, who continues as Assistant General Manager.

Two cadets at extreme left of head table are P. D. Kollasch and W. F. Schill. New president of San Francisco Propeller Club J. J. Geary; Admiral Scammell, U.S.C.G., talking to Hugh Gallagher; Arthur Poole of American President Lines talking with Captain Molcolm Crossman, superintendent of Alameda Officers' School; E. H. Harms, operating manager, McCormick Lines, and Dr. R. C. Dwyer, California State Maritime Academy, and Eugene Hoffman.

S. F. Propellers Christmas Program

Joseph A. Moore, Jr.

Retiring president of the San Francisco Propeller Club, Joseph A. Moore, Jr., has been elected national vice president for the South Pacific Coast Region of the Propeller Club of the United States. Captain Wallace S. Langley of Seattle was reelected vice president for the North Pacific Coast Region, and Professor A. L. Lomas of the University of Oregon was reelected vice president for Student Ports.

One of the outstanding social events of the holiday season was the Propeller Club's Fifth Annual dinner-dance held in the St. Francis Hotel Colonial ballroom. Personnel from the armed services, War Shipping Administration and the Maritime Commission were in attendance.

Edward H. Harms was general chairman and heading the reception committee was Mrs. Frazer A. Bailey, who was assisted by Mesdames Edward H. Harms, Robert Spear, Harry Parsons, George E. Sweet, Hugh Gallagher, Bernard N. De Rochie, George Cooley, Carroll Reeves, Edward J. Schneider, D. N. Lillevand, Edward Martin, Joseph A. Moore, Jr., Joseph J. Geary, Charles L. Wheeler and Eugene Hoffman.

At the December 19 meeting, Joseph J. Geary, prominent West Coast admiralty attorney, took over the presidency and gavel from Joseph A. Moore, Jr., for the 1946 term of the San Francisco Propeller Club.

Other officers are: W. Miller Laughton, 1st vice president; John E. Cushing, 2nd vice president; W. R. Chamberlin, 3rd vice president; and Eugene F. Hoffman, secretary-treasurer.

New gavel swinger of S. F. Propeller's is Joseph J. Geary, prominent West Coast admiralty attorney.

Mariners Club Yuletide Festivities

The annual cammunity sing, sumptuaus turkey feed, and javial good fellowship was the best ever, when the Mariners and friends packed the El Jardin Restourant on December 20, to celebrate Christmas.

Captain Mervyn C. Stone, recently released from WSA, has taken over Part Captain duties of the Matsan Lines.

Matson's New Port Captain in San Francisco

After gathering well-rounded sea experience from the beginning of World War I until 1930 when he joined the Matson Line, Captain Mervyn C. Stone has served on all types of ships, with Matson, and before on the Pacific Mail vessels and the ships of the Panama Mail.

In 1939 he was promoted to Master at Matson and has had command of several vessels. Before Pearl Harbor his runs took him to Suez with lend-lease material for the British during the critical North African campaign. In 1942 on a voyage to Murmansk his ship, the Olapana, was sunk. The survivors were landed by rafts on an island in the Barents Sea and subsequently rescued.

Shortly after Captain Stone's return to New York in 1942, he was released by Matson to become a representative of the WSA in the South Pacific. After 21 months' service and a short leave, he was reassigned to the Central Pacific as assistant regional director.

A CONTINUOUS HORIZONTAL RECORDING OF THE OCEAN BOTTOM WITH THE

NEW BENDIX-MARINE SUPERSONIC DEPTH-SOUNDER

The Bendix-Marine* supersonic depth-sounder has won the acclaim of fishermen all over the world for its simplicity, accuracy, ruggedness and low cost. Both in fishing and in navigation it provides a graphic, faithful reproduction of bottom conditions at all times. *Supersonic* emission prevents false recordings from extraneous sound sources.

Detailed technical information on the performance of this highly valuable navigational aid will be sent you upon request.

No other Depth-Sounder has ALL these features:

Lightweight • Portable • Lower First Cost • Easier Installation • No Relays Required • No Keying Adjustments • No Demagnetizing of Projectors • Uses Dry Recording Paper • Large Unobstructed Viewing Window • Horizontal Graphic Chart • Good Bottom Coverage at All Depths • Works on All Available Voltages • Graphic Recorder in one Compact Unit • Component Parts are Accessible for Maintenance, Quickly and Simply Replaced.

APL Officials Returning

for the Big Job Ahead

Henry E. Frick, vice president in charge of new construction, American President Lines.

At right: Eugene D. Flaherty, general office manager, American President Lines.

Long time vice president and operating manager of American President Lines, **Henry E. Frick,** who was loaned to the War Shipping Administration for the period of the war, returns to the company on January 15. He will be vice president in charge of new construction. He has a big job ahead.

For his outstanding job as commanding officer of the Armed Guard Center (Pacific), **Eugene D. Flaherty** has been returned to inactive duty with both a commendation and a promotion to the rank of Captain. The letter of commendation was from Commodore R. W. Cary, who commands Treasure Island, home port for gun crews of all merchant ships in the Pacific.

Captain Flaherty took leave from APL at the beginning of the war to organize the Armed Guard Center and build it into one of the largest separate commands in the Navy—over 47,000 officers and men.

Captain Flaherty came to the West Coast in 1922 to become secretary to the late Senator W. G. McAdoo in Los Angeles. He came to San Francisco in 1938 when McAdoo became board chairman of American President Lines, and he was promoted to general office manager shortly before the war. During war years this post was one of those occupied by Gene Hoffman.

New Packing Service Announced for Pacific Coast

The France Packing Company, pioneer metal-packing manufacturers, have recently announced the appointment of John Cordes of Cordes Bros., San Francisco, as their sales representative. Simultaneously, they announced a new system of priorities in their plants which will give West Coast customers the same delivery as enjoyed by East and Gulf Coast ship operators.

In making the appointment, E. A. France, president of the firm, stated he "was impressed with John Cordes for his high integrity, his very broad experience, and his wide acquaintance. . . . We want to sell the prospects to whom our packing gives the greatest value for their dollar. That is the company's policy, and we feel John Cordes is best qualified to represent us to the trade in that light."

A new merger will soon make France Packing one of the largest of its kind in the country.

San Francisco Navy Base

The Navy Department announces that all naval installations in the general vicinity have been consolidated into a single administrative unit known as the San Francisco Navy Base, with a new flag officer in command.

Rear Admiral Mahlon S. Tisdale, USN, is commander, U. S. Naval Base, San Francisco. Headquarters of his staff are in the Ferry Building, while Admiral Tisdale's office is Mare Island.

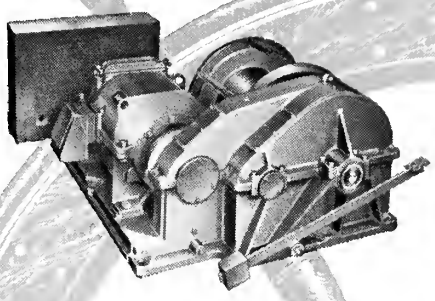
In command of the Mare Island yard is Rear Admiral Grover C. Klein, USN, commander of Naval Shipyard, Mare Island.

San Francisco Naval Base includes 24 Bay Area activities under the command of the district commandant, Rear Admiral Carleton H. Wright, USN.

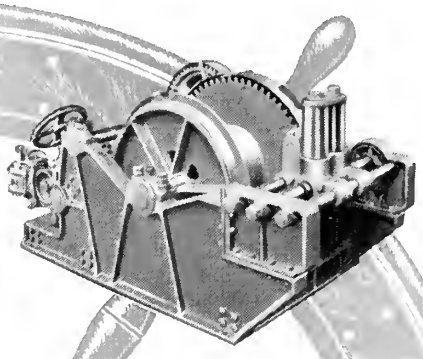
New Helmsman At Penn Maritime Academy

A popular Pacific Coast maritime skipper, Commander Bennett M. Dodson, USNR, has recently taken over the supervision of the Pennsylvania Maritime Academy. Prior to coming to PMA he was foreign supervisor for the U. S. Merchant Marine Cadet Corps in the Pacific Area.

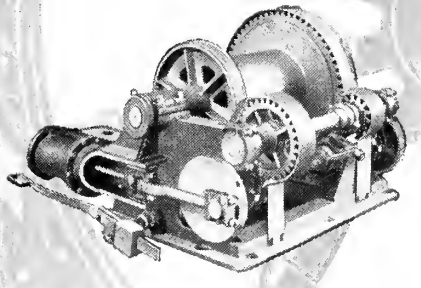
1946 Æ Winches now better than ever



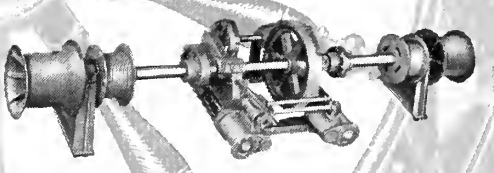
ELECTRIC CARGO WINCH—Single drum, compound geared, one or two mechanical speeds. Built right or left hand with one or two winch heads on close up or extended shafts. Gears totally enclosed.



ELECTRIC TOWING OR MOORING WINCH For towing barges or other vessels at a fixed distance. Single drum, single speed, non-automatic. Non-chafing rollers. Powerful brake bond. Two speeds also available.



STEAM CARGO WINCH—Single drum, compound geared. One or two mechanical speeds. Built right or left hand. One or two winch heads mounted close up or on supported shaft extensions.



STEAM WARPING WINCH—Single or compound geared. Large warping heads on extended shafts or close up . . . Grooved drums for auxiliary steering if desired. Center drum can be incorporated.

Ask about quiet, compact electric types for passenger and passenger-cargo service

Æ winches were always characterized by extreme care in design and manufacture. Now Æ winches are available of Meehanite construction, resulting in stronger, denser, more uniform parts. Consult us for full details of the improved Æ winches.

OAKLAND CONSTRUCTION OFFICE CONSOLIDATIONS

The Hull Technical Section of the Oakland construction office of the U. S. Maritime Commission supersedes the Hull Plan and Approval Section in respect that the Allowance List Section and Cost Review Section have been consolidated into the Hull Technical Section.

The same is true with the Engineering Technical Section. This section supersedes the Engineering Plan and Approval Sction, and consolidates the Machinery Plan and Approval Section and the Electrical Plan and Approval Section into the Engineering Technical Section.

Above: H. E. St. Clair, chief of the Hull Technical Section, Oakland Construction Office, U. S. Maritime Commission.
At right: E. L. Swain, chief of the Engineering Technical Section, Oakland Construction Office, U. S. Maritime Commission.

Heads Army Transportation

Major General Edmond Harrison Leavey, U.S.A., has been appointed Chief of Transportation, succeeding Major General C. P. Gross, retired. He assumed his new command on December 1.

General Leavey returns to the United States after nearly four years of continuous overseas service during which he displayed outstanding logistical skill in both the European and Pacific theaters.

General Leavey accepted the surrender of Japanese forces in the Philippines from General Tomoyuki Yamashita and Vice Admiral Denhici Okochi for General MacArthur, while he was Deputy Commander and Chief of Staff of U. S. Army Forces in the Western Pacific, with headquarters in Manila. He held this post from May, 1945, until November, when he received his new appointment as Chief of Transportation.

As the Chief of Transportation, General Leavey commands all the Army's ports of embarkation, transportation zones, holding & reconsignment points, depots and other fixed installations. The fleet of Army transports, plus others allocated to the War Department by the War Shipping Administration, come under his direction.

Major General Edmond Harrison Leavey, who on December 1, succeeded Maj. Gen. C. P. Gross (retired) as the Army's Chief of Transportation.

Marine Exchange Elects Officers

H. H. Pierson, Pacific Coast manager of the De la Rama Steamship Company, Inc., has been elected president of the Marine Exchange of the Port of San Francisco for the year 1946.

Other officers elected are John Parker, American Marine Paint Co., first vice president; A. E. Kihn, Standard Oil Co. of California, second vice president; Joseph A. Moore, Jr., Moore Drydock Co., third vice president; J. Harding Jensen, Matson Navigation Co., treasurer.

In the recent balloting to select members of the executive committee of the Exchange for the years 1946 and 1947, there were elected W. J. Bush, J. Harding Jensen, A. E. Kihn, L. A. Lunny, H. N. Middleton and J. A. Moore, Jr.

Members continuing to serve on the executive committee during 1946 are L. P. Bailey, W. F. Minehan, John Parker, H. H. Pierson and Roy C. Ward.

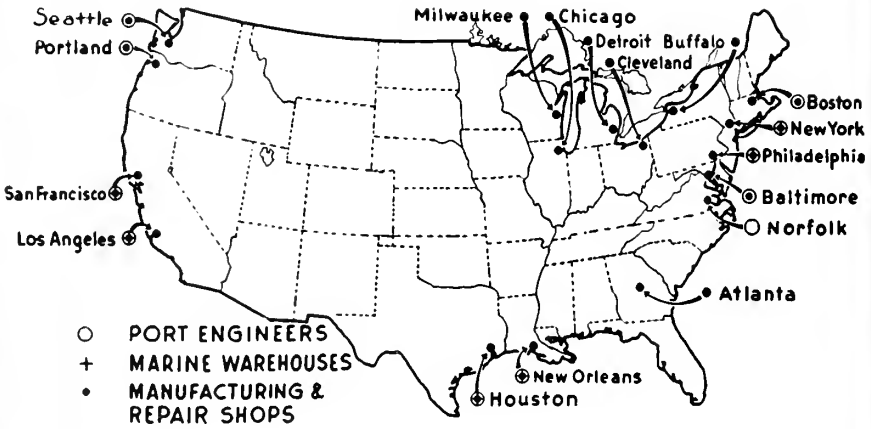
Westinghouse Merchant Marine Service Plan

With the expansion of world trade, the American Merchant Marine will need strategically located service stations at major ports, with engineers and warehouses stocked of spare parts.

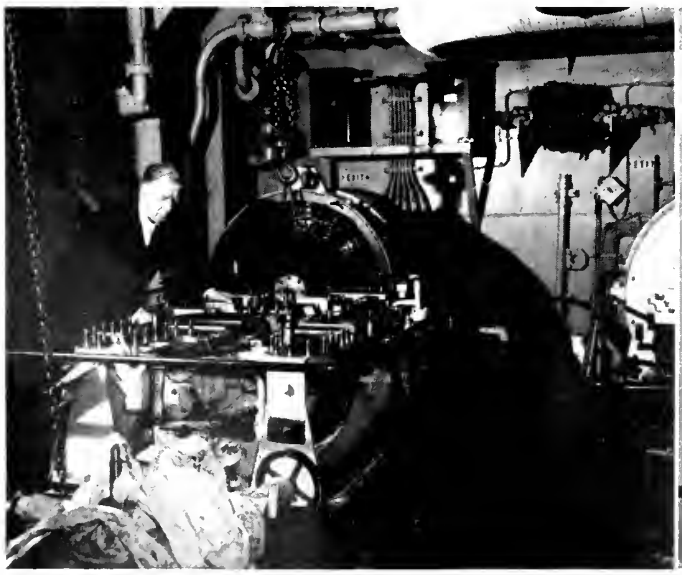
Westinghouse Electric Corporation has provided a plan with port engineers, warehouse stocks of replacement parts and equipment, competent service, repair engineering and shop personnel; and well-equipped repair shops, in each port as shown on the map.

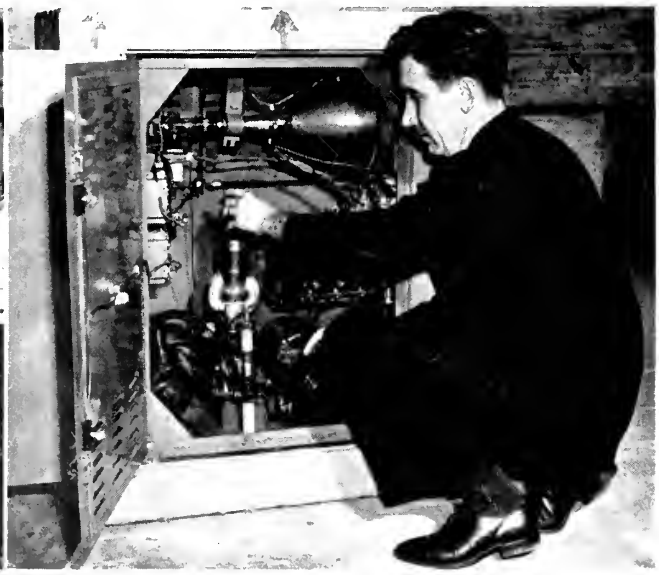
John Baer, part engineer at Las Angeles, is shown inspecting brushes on a 3300-hp main motor abaard an APA-type Navy transpart.

Above: C. D. Singer, part engineer at Seattle, Wash., is pictured inspecting the generator end of a 300-kw Westinghause turbine-generator abaard a Victary ship in Puget Saund.

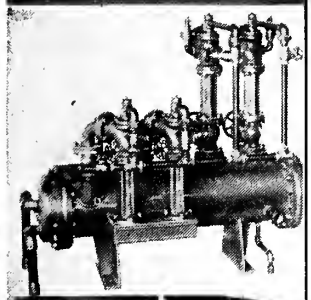


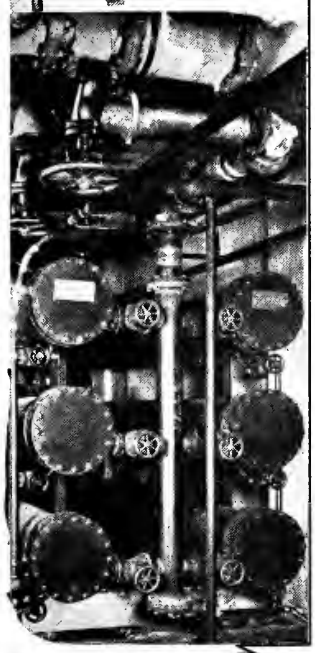
Westinghause Marine Service map showing lacation af Port Engineers, Marine Warehouses and District Manufacturing and Repair Shops canvenient for marine work.

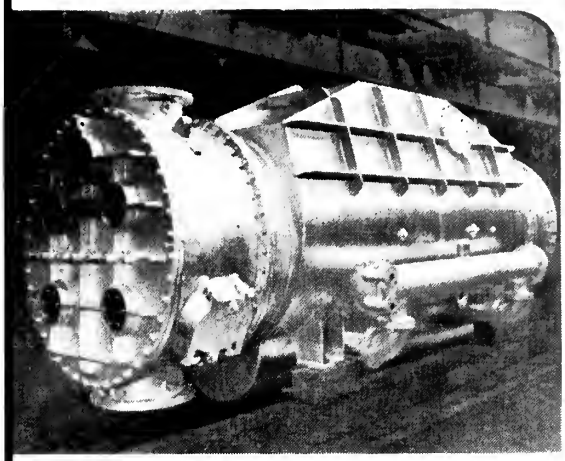


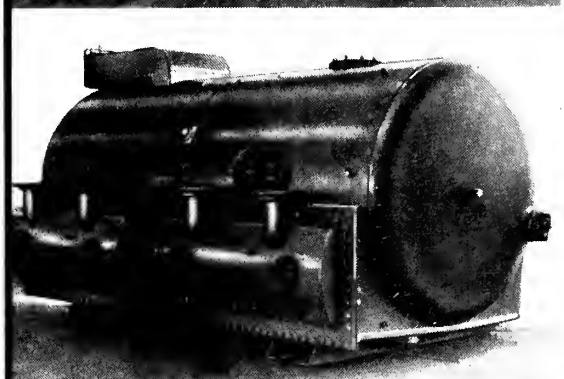


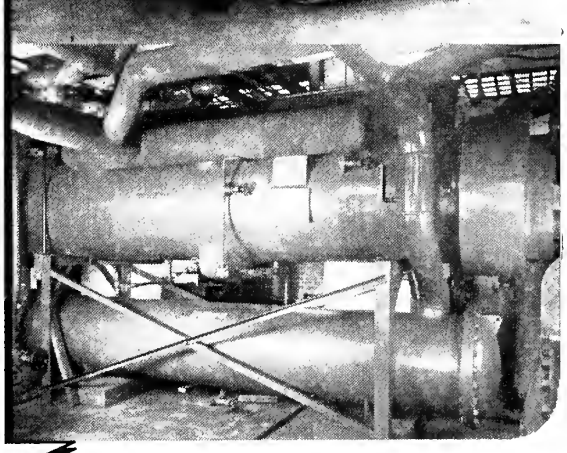
Henry Andrews, abave left, part engineer for the Marine Division at Portland, Oregan, is inspecting the internal canditian af a 300-kw turbo-generator on the SS Berry Victary. At right, William N. Harnberger, port engineer at San Francisco, is adjusting a surge tester used ta check coils an large marine electric matars.











CONSECO

MAINTENANCE SERVICE

Conseco maintains a highly-trained service organization equipped with special tools developed by us to save time, labor and material, ready for action any time of day or night. Condensers, lube oil coolers and other heat exchange equipment are retubed or repaired in the shortest possible time. Years of intensive specialization in retubing work assures best results at lowest cost. Tube sheets, tubes, ferrules, metallic, fibre or corset lace packing, and other necessary materials are always stocked, ready for instant shipment.

Conseco maintains the most modern facilities for calibrating and repairing instruments. Other services include lead coating to increase service life of copper main injection pipe and circulating pump housings, and metallizing to build up worn or broken parts.

The keynote of our service organization is dependable, accurate, *FAST* service performed by competent, properly equipped men working under qualified engineering supervision. Why wait for an emergency? Write for details of our service now .

DEPENDABLE ACCURATE *FAST*

A highly skilled, specially equipped service organization, ready for immediate action anywhere on the continent, backed by engineering and manufacturing facilities producing over 3,000,000 sq. ft. of heat exchangers annually.

Ex-Servicemen Back in Shipping

Al Gatove, former Major in the U. S. Army with the Transportation Corps, has joined the Allocations Division of the War Shipping Administration. Major Gatove was formerly operating manager at Los Angeles Harbor for the Interocean Steamship Corporation.

Another ex-service man returned to the shipping fold recently when Lieutenant-Commander James A. Sullivan, USNR, rejoined the Balfour, Guthrie & Co., Limited, in his former position as manager of the steamship department.

Sullivan was attached to the Port Director's staff at San Pedro, Bermuda and the Canal Zone during the three and a half years he was in the service.

Re-election of John M. Franklin as president has been announced by the United States Lines Co. Mr. Franklin, who held the rank of brigadier general, was recently discharged from the Army where he was in charge of the troop transport division of the Army Transportation Service. After serving as president of the line during the war, Basil Harris has been named chairman of the board.

Major General John M. Franklin, re-elected president, United States Lines Company.

NEWLY APPOINTED EXECUTIVE SECRETARY

Of the Pacific American Tank-Ship Association is Charles H. Robertson. After 25 years with Standard Oil of California, and four war years battling the oil complications in Washington, Mr. Robertson has taken on new problems in the tanker industry. The Association and the industry in general will be well served.

The American-Hawaiian welcomes back Joseph F. Blackett, who returns to his former position the first of January after serving as chief clerk in the operations department of the War Shipping Administration.

Appointment of Allen C. Brown, former Major in the Army Transport Service, as assistant freight traffic manager, has been announced by M. F. Cropley, Matson Navigation Company traffic manager. He succeeds Eugene H. Hurst, who recently retired due to ill health.

Brown, who is a native of Honolulu, worked closely with Matson during the war in coordinating cargo shipments between the Pacific Coast and Hawaii, serving as a liaison officer for the War Shipping Administration.

After four years of Army service, Colonel H. E. Nicholl has rejoined the American-Hawaiian Steamship Company as assistant in Intercoastal WSA service. He will assist A. E. Stow, operating manager.

Colonel Jack A. Fraser, who served served during the war in the Transportation Corps, has joined the marine claims staff of Fireman's Fund Insurance Company in San Francisco. Before entering the Army, Fraser was district manager of the American-Hawaiian Steamship Company at Baltimore, and he was general claim agent for the same line in San Francisco before moving to the East Coast.

After three and a half years of service as traffic manager, handling embarkations for the Army Transport Corps at Fort Mason, San Francisco, **R. G. Dinwoodie** returns to the civilian transportation field as district passenger agent for the American President Lines. He will represent the APL in Southern California, Arizona and New Mexico, reporting to Ronald M. De Long, general passenger agent, Los Angeles.

Another ex-service man to come back to the shipping fraternity is Lieutenant Colonel Leonard Formosa who, after four years of service, has returned to the American-Hawaiian Steamship Company as general freight agent.

Allen H. Jones has joined the Jones Stevedoring Company and Western Freight Handlers, Inc., as vice president following his discharge

from the Army Air Forces where he held the rank of major. Allen is the son of W. Ernest Jones, president of Jones Stevedoring and Western Freight, and the brother of Capt. Gordon Jones and Ernest Jones, Jr., vice presidents of the companies.

After completing special training in the Military Government School, George Latham, former general passenger agent for the Japanese Mail Line in Los Angeles and more lately an Army Captain, has shipped overseas to Japan for duty in the civil affairs division of the occupational forces.

Captain Latham served as Transportation Officer in both Denver and Omaha.

Book Review

Marine Electricians' Library

By J. M. Dodds

In three volumes with a total of 1316 pages 5¼ x 8¼, hundreds of illustrations, tables, and diagrams; bound in red buckram with black and gold stampings; published by McGraw-Hill Book Company, Inc., New York. Price, Volume I, $3.00; Volume II, $4.00; Volume III, $4.00.

This is a very fine piece of compilation by the author and of bookmaking by the publisher. Mr. Dodds is a field engineer of the Pacific District Engineering Division of the General Electric Company and has specialized in recent years on marine applications and installations. He has worked into this library of three volumes the answers to the questions that have been raised by his experience in the marine field, also by his experience as an instructor in the wartime courses given for training marine electricians and the operators of marine electrical power plants.

The result is a library that will, we are sure, prove indispensable not only to the marine electrician but also to any electrical engineer whose work in any way includes the marine field.

Volume I reviews mathematics, physics, mechanics, and electric theory as they apply to marine installations; treats the application and installation of shipboard cable; and discusses communication circuits and devices.

Volume II covers the general subject "Electric Power Sources in Marine Service." Its seven sections treat: the electric machine; the alternating current generator; the direct current generator; the storage battery; controlling and protective devices; switchboards and meters; and installation kinks.

Volume III treats the topic "Electric Power Uses in Marine Service." There are six sections covering: a.c. motors and control; d.c. motors and control; analysis of control circuits; light sources; electric propulsion of ships; and maintenance.

Godfrey Macdonald,
Passenger Traffic Manager,
Grace Line, Inc.

Grace Line Appoints New Passenger Head

Officials of Grace Line, Inc., recently announced the appointment of Godfrey Macdonald as passenger traffic manager. Mr. Macdonald received his promotion after eight years as assistant passenger traffic manager. He has been in the inter-American travel and trade with various Grace interests for a total of 23 years, after leaving Princeton in 1922. Since 1930, he has been associated with the Grace Line, and has been district manager of the company's Philadelphia office, and freight traffic manager of the intercoastal service, which was discontinued in 1938.

Elliott Names New Products Manager

The appointment of **Bingham H. Van Dyke** as manager of the New Products Department has been announced by the Elliott Company, Jeannette, Pa.

Previously assistant to the director of Research and Development, Van Dyke came to the Elliott Company from the War Production Board where he was deputy chief of the Heat Exchanger and Pressure Vessel Branch.

Educated at Cornell University and the University of Pennsylvania, he was graduated from the latter in 1933 in chemical engineering. After graduation he was with the Atlantic Refining Company and The Griscom-Russel Company.

U. S. MARITIME COMMISSION NEWS CORNER

Max Kimball, WSA representative, awarding medal to Martin F. Horeni, assistant to Port Captain at Pacific Tankers, Inc.

Merchant Marine Citation to Two Men Aboard SS Juan Cabrillo

A recent addition to Pacific Tankers, Ltd., as assistant to the Port Captain, is Martin Franklin Horeni, former radio operator aboard the SS Juan Cabrillo, who was awarded a citation and medal for bravery by Admiral Emory Land. The citation said in part: "His courageous acts and utter disregard of personal safety in the face of possible death will be a lasting inspiration to all seamen of the United States Merchant Marine."

Chief Mate Jack Wilson presented medal on SS Kansan: The Merchant Marine Meritorious Service Medal, second highest award of the U. S. Maritime Commission to merchant seamen, was presented at Pier 26, December 18, 1945.

Wilson won the medal while serving aboard the SS Juan Cabrillo in the South Pacific. The freighter was discharging ammunition when a nearby ammunition dump exploded showering fire and shrapnel over the Juan Cabrillo and other nearby vessels. Wilson immediately took charge supervising the fire fighting and clearing his vessel from the pier to a safe anchorage.

WSA ACTS TO STABILIZE TANKER OPERATIONS

As the result of the United Maritime Executive Board's decision to return to American owners 300 tankers of more than 3000 gross tons that were under requisition by the WSA, more than 200 tankers already have been restored to private operation. Prospective voyage charterers of WSA-owned or controlled tanker tonnage must furnish the WSA Tanker Division by the fifteenth of each month with detailed statements of requirements for the following month's operation which cannot be supplied in the open market.

This will include certification that the open market has been thoroughly canvassed and found unable to supply suitable U. S. flag tonnage.

The WSA states that allocations will be for single voyages only, every effort being made to prevent employment of WSA tankers in commercial trades to the detriment of private tanker owners.

USMC Offers Surplus Small Craft

Twenty-five small vessels ranging from sea sleds to subchasers and motor launches which have been declared surplus by the Navy and Coast Guard will be sold under competitive sealed bids by the U. S. Maritime Commission in Washington, D. C. Bids will be opened December 21.

The boats range in size from three subchasers, 110 feet long, to a 35-foot Chris Craft cruiser. Two PT boats and two PT trainers are also included, the first of this type of vessel to be declared surplus and offered for sale. Six of the boats, a cabin cruiser, two Navy launches, and three rescue launches, are located in Los Angeles. A sea sled and six Navy launches are in Seattle. All are being offered on an "as is, where is" basis.

Prospective bidders may obtain invitations by applying to Acting District Manager, 220 Bush Street, San Francisco; Acting Director, 1488 Dexter Horton Bldg., Seattle 4; or to other district offices of the U. S. Maritime Commission.

Steel Barges For Sale

Two hundred and sixty-nine new surplus knockdown steel barges, part located at Lathrop and Yermo, California, and Auburn, Washington, are to be sold by the U. S. Maritime Commission. The barges originally cost the War Department $9,119,000. They are prefabricated, crated and ready to assemble upon delivery. All parts have been marked, and complete blueprints for rapid and simplified assembly are included with each unit. All have been constructed of the best materials under rigid Army inspection and specifications.

Permission to inspect and complete information concerning equipment, specifications, and selling price may be obtained upon application to the Materials Disposal Section, U. S. Maritime Commission, Washington 25, D. C.

New Idustrial Relations Section at Socony-Vacuum

Establishment of an industrial relations section in the Marine Operating Division was announced by the Socony-Vacuum Oil Company, Inc.

Arthur M. Dodge, who is returning to Socony-Vacuum after serving throughout the war in the Coast Guard, will do liaison work with the inland fleet, and **Edward S. Bischoff,** who served for some time as a ship's officer, will act as contact man between the deep sea fleet and the industrial relations section.

J. H. Cox is the newly appointed Engineering Manager.

Westinghouse Engineering Manager at Emeryville Plant

J. H. Cox has been appointed engineering manager for the Westinghouse Electric Corporation's Pacific Coast Manufacturing and Repair Division, with headquarters at Emeryville, California. This announcement was made recently by P. L. Lenz, the division's district manager.

Mr. Cox joined the company in 1923 as a service engineer in New York, later being transferred to the General Engineering Department at the company's East Pittsburgh plant. There he was engaged primarily in lighting, and research investigation of transmission lines and transformers. From 1930 and until his recent transfer to Emeryville, he had been acting as manager of the mercury arc rectifier engineering section in the Transportation and Generator Division.

A native of Nebraska, Mr. Cox received his engineering training at the Massachusetts Institute of Technology, graduating in 1923. A Tau Beta Pi at M. I. T., he received an award in 1926 from the American Institute of Electrical Engineers for the best first paper.

D. E. M. A. Elects

E. J. Schwanhausser, vice president of Worthington Pump & Machinery Corporation, was elected president of Diesel Engine Manufacturers Association at the annual meeting, held December 11 in Chicago.

Gordon Lefebvre, president of Cooper - Bessemer Corporation, and J. E. Peterson, vice president of General Machinery Corporation, were elected vice presidents of D.E.M.A.

Reelected as Treasurer was Robert H. Morse, Jr., vice president and general manager of Fairbanks, Morse & Co.

Harvey T. Hill, executive director of the Association, was likewise reelected to serve through 1946.

New directors are: A. W. McKinney, vice president of National Supply Co., and G. F. Twist, vice president and general manager of Atlas Imperial Diesel Engine Co. Continuing on the Board are: George W. Codrington, vice president of General Motors; Charles E. Brinley, chairman of the Board, Baldwin Locomotive Works; Robert E. Friend, president of Nordberg Mfg. Co.; Norris H. Schwenk, president of Busch-Sulzer Bros. — Diesel Engine Co.; Mr. Schwanhausser, Mr. Morse and Mr. Lefebvre.

Knoll Joins McGee

George Knoll, who was recently released from the Navy, has become associated with the San Francisco office of Wm. H. McGee & Co. as an underwriter.

Mr. Knoll has a fine background for his new position. He started his insurance career nineteen years ago with the ocean marine office of Union Insurance Society of Canton, Ltd.

When the Pacific National opened their marine department in 1937, Mr. Knoll went with them in their Home Office as an underwriter, and remained there until he joined the Navy in 1942.

New Manager Bendix Eclipse Plant

Appointment of Maurice P. Whitney as acting general manager of the Eclipse Machine division of Bendix Aviation Corporation is announced by Malcolm P. Ferguson, vice president and group executive of the corporation. Mr. Whitney, who has been chief engineer of the division, succeeds T. W. Tinkham, recently resigned.

The ship-supply firm of West, Elliott & Gordon—which has been inactive since the start of the war—will resume operations under the ownership of John West, son of the late James West, and **Raymond Flood**, son of the late James Flood, who for many years operated the firm of Flood Bros. in San Francisco. Flood was a Lieutenant-Commander in charge of naval activities at Port Hueneme, California, during the war.

West Coast Engineer to Handle the Davey Line

A veteran West Coast engineer, **S. Herbert Lanyon** of San Francisco, has been selected to handle the Davey Compressor Company's line of air compressors in the northern half of California, according to an announcement by Paul H. Davey, president of the firm at Kent, Ohio.

Mr. Lanyon's organization will be direct factory agents for the Davey concern and will supervise dealer activities in the area north of San Luis Obispo, Kern, Mono and Inyo counties. C. B. Smith, who has had considerable experience in the compressor field, will assist Lanyon.

A mechanical engineer by profession, Lanyon is prominent in the design, manufacture and installation of refractory structures. He also is active as a sales engineer, handling steam power plant equipment, industrial gas burners, oil refinery apparatus, chemical equipment and supplies, and, now, Davey air compressors.

Mr. Lanyon is located at 58 Sutter Street.

H. Norman Miller,
newly appointed Portland, Oregon, manager
for the Westinghouse Electric Corp.

Portland Resident Named New Manager

H. Norman Miller, electrical engineering graduate of Oregon State College and a member of the industrial sales staff of the Westinghouse Electric Corporation for the past 19 years, has been named manager for the company in the Portland area. Announcement of Mr. Miller's appointment was made by Chas. A. Dostal of San Francisco, vice president in charge of the company's Pacific Coast District.

As Portland manager, he will succeed L. G. Fear, who will act as the company's special representative in both the Seattle and Portland areas to better coordinate the expanding scope of all Westinghouse activities throughout the entire Pacific Northwest and Alaska.

Mr. Miller will have charge of affairs of the company in Portland and will direct the numerous Westinghouse men who are being assigned to more adequately serve the increasing fields of specialization, the result of the war's research in the needs of customers, in this important area. These fields include electronics, induction and dielectric heating, welding, communications and others.

A native of Maine and a Naval veteran of World War I, Mr. Miller joined Westinghouse as a graduate student at East Pittsburgh, Pa., in 1925, two years after receiving his electrical engineering degree at Oregon State.

Robert Digges

Marinship Executive Changes

In order to fill the administrative post held by William E. Waste, who has taken over duties as President of Bechtel-McCone Company, construction and engineering firm in San Francisco, Robert Digges, former administrative manager of Marinship Corporation for the past 3½ years, has been named General Manager. Suceeding Mr. Digges as administrative manager is William R. Ayers, who has been administrative engineer. K. K. Bechtel will continue as president of the corporation and Mr. Waste will remain a vice president and director.

Paul W. Eberhardt

Paul W. Eberhardt

The Board of Directors of Walter Kidde & Company, Inc., announced that Paul W. Eberhardt has been elected to the office of a vice president. His principal duties will include management of domestic sales of the company's fire-fighting equipment in aviation and general industry, together with general supervision of field selling activities.

Mr. Eberhardt joined the company in 1926 as manager of the Public Utility Department to assist in the development and sale of fire protection equipment for this field. In 1928, in recognition for the development of valuable markets, and wide customer goodwill, he was made manager of the Industrial Department (the Public Utilities Department being merged therein) and in the early part of 1944, Mr. Eberhardt was given in addition full responsibility for the activities of the field sales force. This latter field now covers all industrial and utility sales in the United States for Walter Kidde & Company.

Todd Delivers 1000th Vessel

The mark of 1000 ships completed during the wartime period by Todd Shipyards Corporation was reached November 28 with the delivery of the Raccoon Bend, a T-1 tanker of 4200 tons, to the Maritime Commission by Todd Houston Shipbuilding Corporation. The tonnage of these ships totals 6,183,600 deadweight.

The delivery of the Raccoon Bend brought to more than 115,000,000 deadweight tons, representing nearly 22,000 ships sent to sea by Todd Shipyards Corporation from December 7, 1941, to V-J Day.

Todd shipyards during the wartime period repaired and constructed virtually every type of vessel. Besides repair work, the corporation constructed destroyers, aircraft carriers, liberty ships and submarine and destroyer tenders.

J. Fraser Rea, head of Plastics Division, Western Fiberglas.

Personnel News at Western Fiberglas

Gayle R. Dutton, president, announced that **J. Fraser Rae,** former plastics instructor and consultant for the University of California, has joined the firm as chief of its Plastics Division. Besides his work for the University of California, Rae, who is a graduate of Scotland's famed Aberdeen University, has been special consultant on plastics for various technical schools, and for the U. S. Navy. He is a member of the Society of the Plastics Industry, and the author of numerous articles on plastics and their post-war applications.

E. O. Rapier, Western Fiberglas Supply Co.

Gayle R. Dutton announced further expansion of company personnel, with **Edmond O. Rapier** joining the firm in the capacity of Low Temperature Sales and Construction engineer. For the past 15 years Rapier has been engaged as sales and construction engineer of cold storage plants.

Sides to Head Todd Brooklyn Division

Andrew B. Sides, president of the Todd-affiliated New England Shipbuilding Corporation, has been appointed general manager of the Brooklyn division of Todd Shipyards Corporation, succeeding J. William Jamin.

Walter L. Green, vice president and general manager of the New England yard at South Portland, Me., will become operating manager of the Brooklyn plant, succeeding Henry F. Gelhaus. Mr. Jamin and Mr. Gelhaus assumed new duties effective January 1 in the corporation's peacetime plan of operations.

Dean P. Hunter, president, Port of Portland, Propeller Club.

Assistant Chief at Caterpillar

R. R. Robinson has been named assistant chief engineer in charge of engine design at Caterpillar Tractor Co., it is announced by G. E. Burks, chief engineer of the company.

Mr. Robinson joined Caterpillar in 1934 as an engineering apprentice of the college graduate training course after his graduation from the University of Nebraska.

Upon completion of his training in 1936 he joined the engineering department. He became supervisor of engine design and after serving in various positions throughout the department, was appointed general supervisor of the engine design division.

R. R. Rabinson, assistant chief engineer, in charge of Engine Design.

Portland Port Meeting

Frank Gillard of Portland, Oregon, speaking on behalf of the Portland Port, extended an invitation to hold the 1946 National Propeller Club meeting in that city. The invitation was supported by letters from the Governor of the State of Oregon, the Mayor of Portland, and the President of the Chamber of Commerce.

The Portland invitation was endorsed by delegates from Seattle, Tacoma, Los Angeles-Long Beach, San Francisco and Boston. President Gehan expressed the appreciation of the national organization for this warm invitation, and suggested that the matter be referred to the National Board of Governors or the Advisory Committee, with a decision to be made, depending on travel and other conditions, by March, 1946.

SAVERITE'S DISTRICT REPRESENTATIVE

A. K. Granrud, left, recently appointed district representative of Saverite Engineering Company, made a tour of the plant in Las Angeles. While on tour he greeted Fred M. Smith (right) of Lee Smith & Don, distributor for Saverite products in Eureka, California.

Rose Queen Sponsored Consolidated Steel Ship

The SS National Eagle, the fourth of a fleet of ten huge C-2 cargo vessels, was launched from Consolidated Steel's Wilmington shipyard December 21. The sponsor was Miss Patricia Auman, Queen of the 1946 Tournament of Roses. Master of ceremonies was Everett H. Seaver, assistant to the vice president of Consolidated Steel Corporation.

The SS National Eagle, together with her nine sister ships, are the largest vessels to be built at Consolidated's Wilmington yard.

These C-2's are 460 feet long, have a beam of 63 feet, and a molded depth of 40′ 6″.

NECROLOGY

The De Laval Separator Company announces with deep regret the death of Dr. Alan Estes Flowers, 69, on December 3. Dr. Flowers, for more than 20 years head of the Research and Development Department for the company, was highly regarded in engineering circles, and a member of several societies.

He was associated for many years with the leading electrical companies and was well known as a teacher. He served for five years as professor of electrical engineering at Ohio State University. He was an inventor, author and authority on many subjects, and his best-known writing is the chapter on centrifuges in the Chemical Engineers Handbook.

Dr. Alan Estes Flowers

C. Harold Wheeler, Jr., 63, vice president and general manager of the C. H. Wheeler Manufacturing Co., Philadelphia, passed away on November 24. Mr. Wheeler succeeded his father, who founded the firm, as general manager in 1923. He had pioneered many developments in the steam condenser industry.

He was a director of the National Bank of Germantown and Trust Co., a member of the Pennsylvania Advisory Board of American Mutual Liability Insurance Co., the American Society of Mechanical Engineers, the Union League and the Whitemarsh Valley County Club, where he was one-time golf champion.

WESTINGHOUSE BRANCH AT TACOMA

Top: General view of offices and display floor at the new Westinghouse branch at Tacoma, located at 1930 Pacific Avenue.

Below: Group of guests and officials at the open house held an November 19.

WELL-KNOWN WATERFRONT PAINT SALESMEN

Left: Tom J. Surface, and (right) Frank D. Requa, Southern California salesmen for General Paint Corp.

T. J. Surface and Frank D. Requa, two Southern California marine salesmen for General Paint Corporation, are doing a fine paint-selling job along the waterfront in Wilmington.

Tom Surface came to the company in 1940, after completing a four-year hitch in the Navy. It was during his enlistment that he made up his mind to sell paint to the marine trade, stating that he would rather sell paint to the Navy than apply paint to the Navy's ships.

He worked his way up from the bottom to manager of the Wilmington branch, where he in cooperation with Frank Requa, have covered the waterfront, building trade and industrial accounts.

Frank D. Requa started in 1926 with the Bradley Wise Company, which was later absorbed by the General Paint Corporation in 1929. When he first came to the firm he was employed as chemist, later promoted to salesman, then branch manager, where he had charge of the Huntington Park branch for many years.

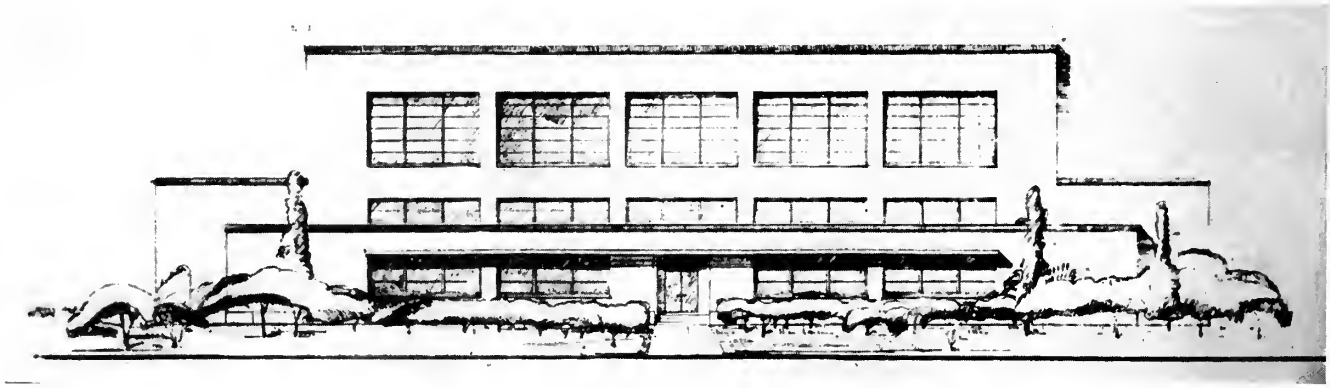
During the war, he was drafted back to the Lacquer Plant to keep this plant in operation, after the loss of so many key men to the Army. Now he is back on the waterfront in Wilmington, offering expert advice on paint problems.

Enters Chemical Engineering Firm

G. S. Myers, of the chemical engineering staff of Eshelman & Potter.

To the staff of Eshelman & Potter, combustion and chemical engineers, of Birmingham and Charlotte, N. C., comes G. S. Myers. As a member of the chemical engineering staff, Myers' work will involve both Hagan combustion control and Hall Laboratories water conditioning in Southern Areas, including the marine field. Myers is a graduate of Georgia Institute of Technology.

G. E. Plans Expansion at Anaheim



General Electric Company glyptal plant at Anaheim, California.

The General Electric Company plans to build an additional factory on the 12 acres of land they purchased some months ago in Anaheim, California. The new project, now in the designing stage, will be given over to the manufacture of Glyptal alkyd resins for paint base, and will operate as part of the G. E. Chemical Department's Resins and Insulation Materials Division.

Although at the same location, the new plant is in addition to the factory being designed for the plastics division of G. E. Chemical Department.

Both projects are part of the expansion that General Electric plans in anticipation of the vast increase in the industrial growth of the Pacific Coast region.

Admiral Bowen Honored

Honorary membership in the American Society of Mechanical Engineers was conferred upon Rear Admiral Harold Gardiner Bowen, USN, Chief of the Navy's Office of Research and Inventions. The highest award of the Society was granted specifically to the Admiral's daring and radical innovations in the application of high pressure, high temperature steam which resulted in decidedly changed construction of U. S. ships and naval power plants. New boiler designs which embodied super heat control, economizers, air casings and a capacity for 40 per cent overload were adopted.

Hot off the Press

Coolant Filter Bulletin

Cuno Engineering Corporation of Meriden, Conn., has just published a bulletin on its new Coolant-Klean filter, designed to remove abrasive and metallic particles from grinder coolant. It is a compact, replaceable-element type filter applicable to unit machines or centralized system. It may be applied to any type of grinder or any machine using a coolant or cutting oil.

Average cost of operation is reported to be a few cents a week. Installation is accomplished in about 15 minutes, because no alteration of the grinder is required and in most cases only two hose connections are needed. The filter does not require extra pumps, electrical work, plumbing, valves, by-passes, or filter aid.

De Laval Steam Turbine Co. have published a booklet entitled "Useful Shaft Data," which should be a great time saver for any one whose work involves determination of required shaft sizes. It includes tables, curves and formulas for computing torque, deflection angle of thrust, bending moment, and other factors in solid, hollow, keywayed and stepped shafts.

Bulletin W-204-B10 has been released by Worthington Pump and Machinery Corporation and covers their low level jet condensers mounted on horizontal single wet vacuum pumps, for steam engine, small turbine or process applications.

J. A. Zurn Mfg. Co. has published a 68-page illustrated catalog of its marine products. This book should serve as an authoritative reference text for marine designers and engineers, purchasing officials, shipbuilders and operating and maintenance mechanics.

"Schloemann Extrusion Presses" is the title of a folder from Schloemann Engineering Corporation. It illustrates the presses and shows samples of sections extruded by them.

"How to Get More Elevator in Less Space" is the title of a new Roto Drive bulletin announced by Sedgwick Machine Works. This bulletin explains how the Roto Drive operates and gives its advantages. Text and illustrations show why the elevators cannot overtravel and how they can be installed entirely within the trunkway without run-by zones penetrating valuable deck space.

Selby, Battersby & Co. have available a folder on their product, "Komul," a cold-applied, anti-corrosive coating, which locks moisture out, resists acids, alkalies, gasoline, oils and greases, and seals concrete tanks.

Catalog M-6, covering "Varec" approved marine equipment, is a 64-page recent release of The Vapor Recovery Systems Company. The book is indexed alphabetically and numerically; contains diagrams of installations; sizes and dimensions; price lists; and approximate net and shipping weights.

"Bestco Tackle Blocks," catalog #45, published by the Bestco Mfg. Corp., contains the latest list prices and descriptions of the various sizes of tackle blocks manufactured by that firm, one of the best equipped block manufacturing plants in the West. During the war period production was 100 per cent for the Maritime Commission, War Shipping Administration, and the U. S. Army and Navy. Now the plant is ready for service to industry.

Catalog 452, a new bulletin describing industrial machinery, castings, mining machinery, marine winches, and specialized industrial products, has just been issued by Lake Shore Engineering Company. It shows the wide range of the company's products from tourist camp stoves to 15-ton castings, and also the company's facilities for manufacturing products on contract or building special equipment.

Wilber & Son have released a new 1945 catalog of Wilco life preservers and sleeping bags. Some of the items may not be immediately available, due to the heavy demands made by the war, but all of them should be within a reasonable length of time. The catalog contains a list of life-saving devices for pleasure craft and commercial vessels and gives the Government requirements.

Hot Off the Press

Ideal Commutator Dresser Co. has available a 36-page booklet featuring motor-generators maintenance and repair equipment for reconditioning war-weary machinery. It has sections devoted to commutator care, troubles and remedies; resurfacers; precision grinders; mica undercutters; commutator saws and milling cutters; coil winder drives and heads; and many other phases. The specifications are comprehensive and the booklet is fully indexed.

American Flexible Coupling Co. has published a folder on its couplings covering engineering data, construction features, lead factors, and dimensions and maximum bores.

Victor Equipment Company has published a 34-page booklet, in full color, covering its cutting torches and cutting attachments. It carries full specifications and price lists and is a very convenient and informative reference booklet. Also available is Form No. 1, entitled "Setting Up a Victor Welding or Cutting Unit." This is a 46-page, fully illustrated publication describing in simple language how to assemble a welding or cutting unit. The company has also published Bulletin W-2, which contains 32 pages of text and illustrations describing the Ampco-Trode Welding Technique.

Reliance Electric & Engineering Company recently published an instruction sheet (#3042) covering the grease lubrication of anti-friction bearings. The 4-page bulletin details construction, maintenance and lubrication recommendations for double-shielded ball, open ball and spherical roller bearing types.

"The Dillon Dynamometer" is the title of a folder from W. C. Dillon & Co., descriptive of their Model "AN," which speedily and accurately measures tensions or applied stresses.

Clipper Manufacturing Co. has prepared a practical index to cutting information for the operators of all Clipper masonry saws. The book is well illustrated and fully indexed and contains many helpful suggestions for masonry construction.

A 24-page illustrated booklet describing the many applications of the chemical melamine in the plastics, textile, paper, leather, chemical, paint and allied industries has been published by the American Cyanamid Company.

Rogers Machine Works, Inc., has recently released a catalog descriptive of the "Perfect 36" vertical turret mills. It contains the inside story, shows boring, turning, drilling and thread cutting set-ups, and illustrates the mills in operation.

A new 16-page illustrated catalog, No. 45, has been published by Shook Bronze Corporation, and covers ready-to-use bushings and machined bronze bars made of a special phosphorized bearing bronze. It lists over 800 stock sizes of machined bushings of this new bronze.

Hendy Series "50" is a 16-page booklet released by Joshua Hendy Iron Works, descriptive of their 350- to 675-hp marine diesels. The publication is generously illustrated, including a dimensional drawing as well as general specifications and chart of power rating curves.

"Remote Control Equipment" is a 40-page booklet published by Piezo Manufacturing Corp., which lists 108 different remote control gears, joints and accessories. It includes engineering drawings showing dimensions of equipment and technical data, also photographs of remote control units and accessories, and tabular data on sizes and specifications. It is a useful book to anyone interested in remote controls of valves, machinery or equipment in industrial and chemical plants, power stations or ships.

The De Laval Steam Turbine Company has available a new catalog, No. 1181, describing its complete line of steam turbines, helical gears, centrifugal pumps, centrifugal compressors, worm gear speed reducers, and IMO oil pumps.

"Marine Mufflers" is a four-page bulletin available from The Fluor Corporation, Ltd. It illustrates and describes the Fluor air-cooled muffler and its application on main propulsion engines and individual power units for such auxiliaries as driving pumps and generators; also its use to ventilate and heat engine rooms, other compartments, and pilot house.

Seven manuals to help foremen, supervisors and department heads solve employee relation problems during reconversion and post-war production are described in a catalog available from Elliott Service Company, Department M-28, 219 East 44th St., New York 17. A sample set of the booklets will be sent without charge to executives who are in charge of 15 or more supervisors, or their training, upon written request on their company letterhead.

Hot Off the Press

The Darcoid Company has published a folder on its Edgetallic gaskets. It contains lists of sizes, types, and prices, and covers the complete line of gaskets, which provide perfect seal against high pressures, high temperatures, steam, oil, gases and liquids.

A new 12-page booklet, entitled "Faster, Better Finishing of Metal, Plastic and Glass," describes the 3-M Wetordry Method of precision grinding and finishing at high speed. This booklet from Minnesota Mining and Manufacturing Company is generously illustrated, shows actual industrial applications, and explains how this method keeps operating heat at a minimum; eliminates distortion, discoloration and plastic flow; greatly increases the life of abrasive belts; and eliminates the hazard created by dust.

The effects of vibration on plants, equipment and personnel, and methods of controlling it, are explained in a new 12-page bulletin, "Vibration in Industry," published by The Korfund Company, Inc.

General Electric has available a folder covering its new semi-interference-type mechanical interlocks, a-c magnetic reversing starting, for full-voltage starting of squirrel cage induction motors.

YOURS FOR THE ASKING!

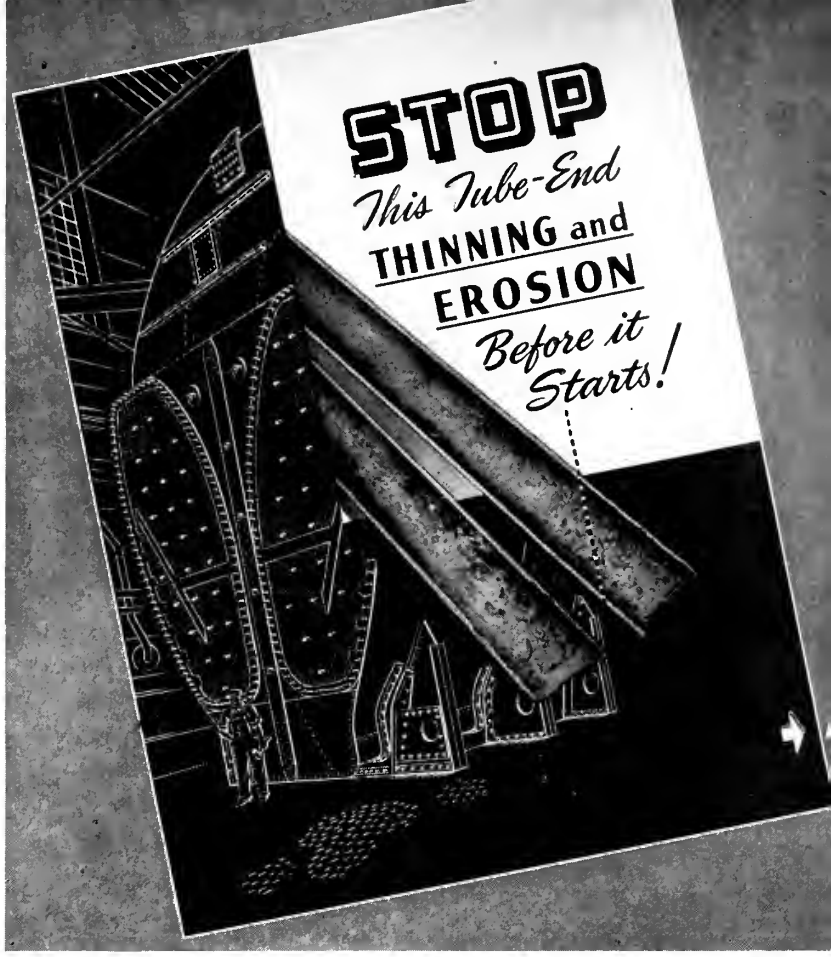
CONDENSER TUBE PROTECTORS: A new bulletin which completely describes the John Crane condenser tube protector has just been issued by Crane Packing Company, 1824 Cuyler Ave., Chicago 13. These protectors were developed after recognition of the fact that most tube failures due to thinning and erosion occur at the inlet ends of the tubes, as illustrated in the cut. The tube protector is made of a special plastic material, is highly resistant to abrasion, and armors the mouth and entrance section of the tube itself.

This bulletin is fully illustrated with typical installations and sectional views. Copies are available from the manufacturer on request.



EDCO ELECTRODES: An attractive new folder on Edco welding rods, with suggestions for their use on copper and bronze as well as on cast-iron and steel, or on combinations of these, has just been issued by Eccles & Davies Machinery Co., Inc., Los Angeles. Industrial consumers, and the welders themselves, will find useful tips in the folder's 16 pages.

Write to Eccles & Davies Machinery Co., Inc., 1910 Santa Fe Avenue, Los Angeles.

Hot Off the Press

The Deming Company recently published a 20-page illustrated booklet entitled "Facts You Should Know About Centrifugal Pumps and Impellers," applicable to all makes of centrifugal pumps. This publication might well be considered a textbook, and should be helpful to those who are directly involved in the application and selection of centrifugal pumps of all standard types.

B. F. Goodrich Company has available a broadside on its new Pressure-Sealing Zipper. It will be used on pressure ducts, dark room tents, sporting goods, footwear, luggage, weather seals and doorways. The seal will not let gases or liquids through, even under high pressures. This product has been going exclusively to the military, but it will probably be available for civilian use soon.

Also available is a new edition of the catalog on the properties of Ameripol D, an oil and heat resistant synthetic rubber. Properties of Ameripol are outlined in detail, and there is a page table giving the property relation of natural and various types of synthetic rubber, as well as a guide to determine where the use of Ameripol D is practical.

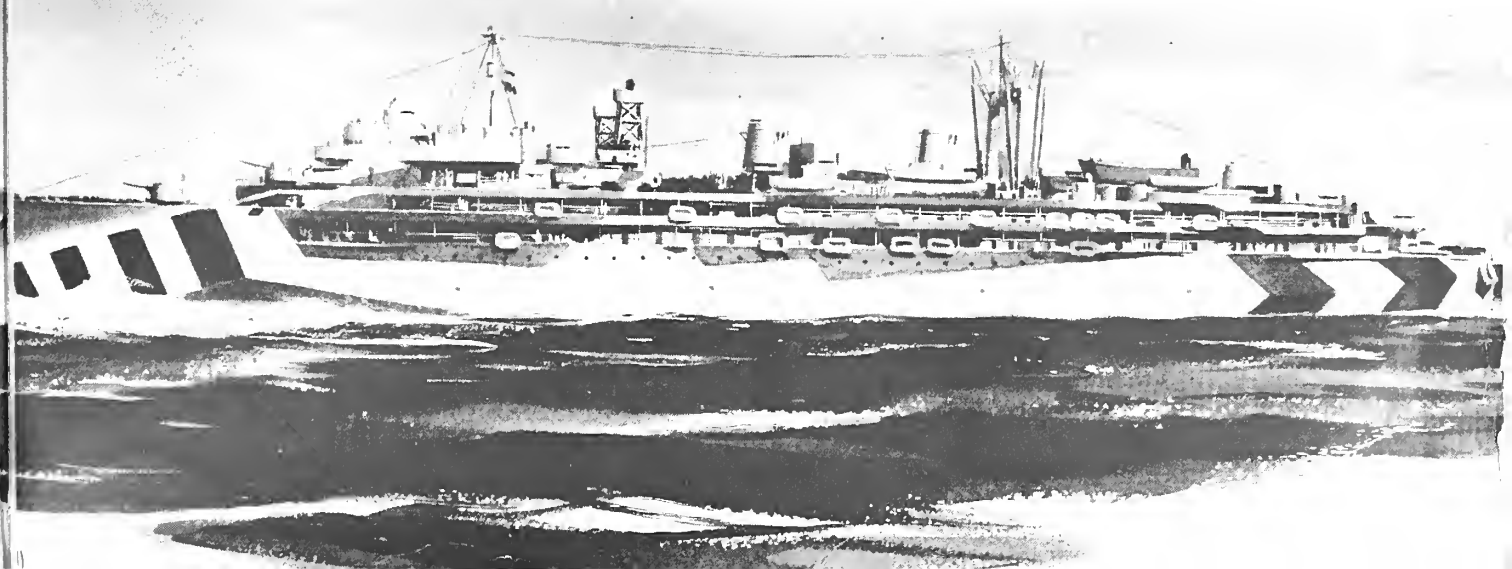
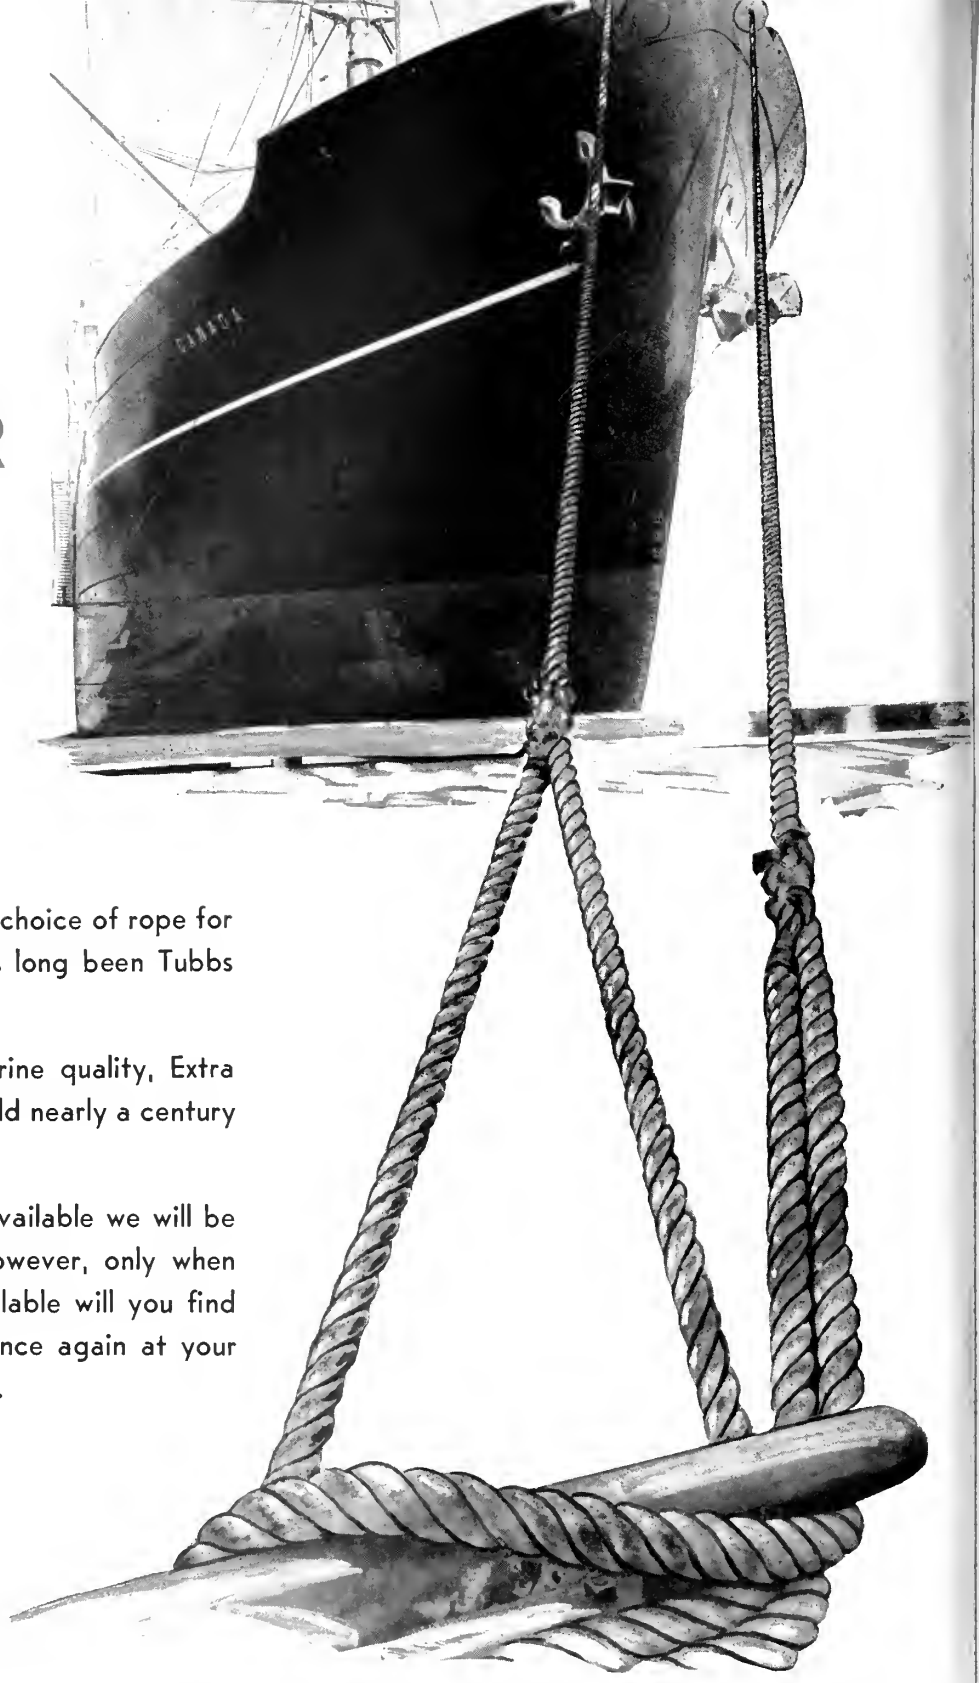
The Howard W. Gilmore, one of the latest additions to the Navy's fleet of submarine tenders. She's named for "Take 'er down" Gilmore, the noted submarine hero.

As with the other tenders of the fleet, the Gilmore carries 12,000 Diesel-Electric horsepower—power provided by engines built by the Cleveland Diesel Engine Division of General Motors.



WHEREVER THEY TIE UP



In every port of the Pacific, the definite choice of rope for dependability and ease of handling has long been Tubbs Extra Superior Manila.

Made to the highest standards of Marine quality, Extra Superior Manila brings to the Marine field nearly a century of "know how" in rope making.

As soon as Manila fiber is once more available we will be able to supply Manila rope again. However, only when the highest quality Manila fiber is available will you find the Extra Superior Manila trademark once again at your suppliers. It will pay you to watch for it.

BEFORE the War, our own organization in the Philippines selected the pick of the crop of manila fibre. They bought, graded, and packed the fibre which was made into the famous COLUMBIAN TAPE-MARKED PURE MANILA ROPE. Naturally, the war destroyed that organization and its facilities as a working unit.

Today, we are busily rebuilding that organization and its facilities under the most extreme difficulties and Pure Manila fibre under the Columbian label will be among the early ship cargos of fibre from the Islands. We cannot now tell you just when this will occur nor how soon Columbian Tape-Marked Pure Manila Rope will again be available. We do want to assure our customers that we are bending every effort to hasten the day when it will be plentiful enough to supply the great need for a high-quality, completely dependable rope. We believe that that day is not far off!

New Passenger Ships—
Are Our Ports Keeping Pace?

Pacific MARINE REVIEW

In a current compilation by the National Federation of American Shipping, which represents about 95 per cent of all American steamship owners, 11 of the nation's largest steamship companies plan to obtain 89 new passenger and passenger-cargo combination ships of about 1,200,000 gross tons, estimated to cost between 400 and 500 million dollars.

Port passenger facilities will need much overhauling to match these new ships.

The 89 new vessels will have a total carrying capacity of 14,000 to 15,000 passengers, and speeds of from 16 to 30 knots against a pre-war range of 12 to 22 knots.

These vessels are in addition to 52 ships of nearly 500,000 gross tons and more than 12,500 passenger capacity which the same companies operated prior to the war and which are expected to be returned to service Nor do they include the ships of such companies as Matson whose pre-war vessels will be restored to them, but whose announcements of new acquisitions include cargo types only. The 11 lines whose programs have been announced are:

Grace Line, 9 vessels for South American routes
Moore McCormack, 5 vessels for South American and Scandinavian routes
United Fruit, 20 vessels for West Indies, South and Central American routes
Alcoa, 5 vessels for West Indies and South American routes
Agwi Lines, 5 vessels for West Indies routes
American Export Lines, 3 vessels for Mediterranean, Near East and North African routes
American President Lines, 19 vessels for Orient and round-the-world routes
Mississippi Shipping Co., 3 vessels for South American routes
American-South African Line, 8 vessels for South and East African routes
United States Lines, 6 vessels for Western Europe routes
American Mail Lines, 6 vessels for Orient routes

Passenger accommodations will be superlative in all classes, featuring innovations in design of furniture, lighting, and arrangement of interiors; air conditioning; telephones; glassed-in promenades; swimming pools, and all the results of years of careful planning. Improvements will be found in all passenger classes.

But there will be competition for the passenger trade. Airlines and railroads are also planning the best. And they are making their terminal facilities match their travel facilities. Every possible convenience is planned for the traveling public so the beginning and ending of a journey may not be unpleasant.

Seagoing passengers will not be so fortunate. They will find the same traffic-congested, hard-to-reach pier sheds, with cold, (or hot), drafty, comfortless waiting rooms. No pleasant surroundings, no ornamentation, no ordinary conveniences, often no telephones, no information services and sometimes no chairs. Recently a leading shipping executive estimated the cost of modernizing New York port in millions. The same could be said of San Francisco and many other ports. All ports require some improving.

There are extenuating circumstances, of course. The shipping industry has gone all-out for the war effort. In San Francisco, for instance, the pier facilities are owned by the State and rented out on 30 day leases. Other ports have other self-justification.

But the public must be pleased.

An airline company can announce prospective expansion in a city, and the city will go berserk to issue bonds to move main highways and build airports and appoint officials to divert traffic to the airline. **What do they do for the steamship line, which makes their city what it is?**

This is a challenge to an industry that has solved many problems. **It must solve this one too.**

Engineering Service to Customers

By George Barr

Marine Superintendent, General Electric Company, San Francisco

George Barr

George Barr, marine superintendent of the General Electric Company, has been very well known in the San Francisco Bay area for many years. A product of the River Clyde, he joined the company's Turbine Department in 1909 and has taken a prominent part in building, operating and repairing turbines ever since. He was transferred from Schenectady, N. Y., to San Francisco in 1918 to supervise installation of main propulsion machinery in 46 destroyers which were built at the Union Iron Works. His whole life's work has been in troining for the prodigious task he so aptly describes.

DURING THE RECENT shipbuilding campaign the amazing production of warships and merchant ships wrote a new chapter in the nation's history. This marvelous engineering feat was made possible by a number of factors which need not be enumerated, but behind it all was the dire necessity of self-preservation.

During the first world war the Government realized that the Allied nations would be defeated unless ships could be produced faster than they could be sunk, so they inaugurated a system of mass production, something that had never been attempted in the history of the trade. The design was frozen, contracts for machinery were distributed amongst the largest manufacturers in the country and the system worked to perfection.

The program laid out to meet the demand of World War II followed the old pattern, but on a much more comprehensive scale, as it was possible to take advantage of the improved technique in hull and machiery production which was developed in the years between.

The total output during the last four years was so enormous that there is nothing to compare it with, but the part played by some of the shipyards in the San Francisco Bay area may be used to gage the activities of other large shipbuilding centers, and now that the ships have been built and have fulfilled their most important mission, the story can be told without reservations and with a great deal of satisfaction.

In the San Francisco Bay area the General Electric Company furnished main propulsion machinery for 320 ships with an aggregate of 2,603,500 hp. They also furnished, for these ships, auxiliary turbine generators with a combined capacity of 134,350 kw. The auxiliaries alone could furnish enough power and light for a city of 70,000 inhabitants. The company also furnished experienced personnel to assist in the installation and testing of all this equipment.

After the first hundred ships were delivered the work became more or less routine, but from first to last the highest quality of workmanship was required and at no stage was the quality reduced to step up production. As evidence of this it may be interesting to note that one well-known shipyard in Oakland delivered 85 ships in a row the day after the sea trial and every ship made its official trial on schedule and without a single hitch.

As the war progressed San Francisco became headquarters of a vast fleet of ships, and wherever ships harbor, repairs must be made; so it was in this field where the most difficult and most essential part of General Electric's marine effort was expended.

The growth of our repair work is plainly illustrated in the following table:

1942	4 vessels
1943	13 vessels
1944	221 vessels
1945	377 vessels

The largest list was in June, 1945, with 51 ships under repair.

This list included ships of all classes, from the largest airplane carrier to the most humble freighter, and the jobs varied all the way from a few days to a few months. The longest jobs were on battle-damaged ships, where in many cases the entire engine room was gutted.

Regardless of the huge output of new ships, the demand for bottoms was so great that at no time, before V.J. Day, were there enough to fill the demand, with the result that many an obsolete vessel was dragged from the graveyard and given new life. Some of these vessels were famous old passenger liners that circumnavigated the globe for 20 years without missing a beat. Necessity made it essential that these ships be salvaged, and so it was. They were not patched up as a temporary expedient, they were really overhauled from truck to keelson and from stem to stern, and after completion they equaled the speed and efficiency which they made on their acceptance trials 25 years ago. Furthermore, they carried thousands of troops to the far-flung battle line, and better still, they are bringing them home today and making the same fast turn-

around for which they were always famous.

The story of one of these ships illustrates what is meant by the term, "Major engine repairs." This ship, originally christened after one of our most illustrious Presidents, but now rechristened and quite unrecognizable, came home to San Francisco to join the big parade of troopers, but her old turbines were not equal to the occasion; so, on account of the extreme importance of her mission, it was necessary to rebuild them. The job was secured by the General Engineering and Dry Dock Company, and the General Electric Company furnished an experienced turbine man to assist, although it so happened that the turbines were not of General Electric manufacture.

A list of the worn-out parts would make monotonous reading, but it is quite simple to list the parts that were usable — turbine casings, diaphragms and rotors. Everything else had to be replaced and no spares or renewal parts were in existence; they had to be made on the spot and from samples of the worn-out parts. The turbine castings had lost all traces of the original machined surfaces and natually their joints leaked enough steam to make the engine room unbearable, and the internal condition was so run-down that the turbines ate up steam and gave nothing in return; in other words, they were highly inefficient. The accompanying photographs show some of the detail parts in course of manufacture, but no picture or description can show the perseverance and the skill behind such an undertaking. The job consumed well over two months "working round the clock" and "round the calendar" as well, but the payoff was a set of engines that developed their normal rating at the original efficiency and turned up the same speed as they made on their acceptance trials 27 years before.

Complete set of flexible pin couplings manufactured for old turbines.

In the past the biggest bottleneck

Reassembly of low pressure rotor after correction, U.S.S. Pinkney.

in this job was the lack of renewal parts, and this has always been the limiting feature in ship repair work. To do its part in rectifying this situation, General Electric has greatly expanded its marine warehouse and servicing facilities. As announced on September 1, 1945, over a million dollars was used for this purpose in New York and San Francisco alone. The expansion includes enlarged parts stocks, streamlined shop repair facilities and expert shipboard repair service.

No port in the United States has had a better opportunity to build up marine repair facilities and especially marine repair technique than San Francisco, and, as soon as the decks are cleared for action, there must be busy days ahead.

General Electric in the New American and Brazilian Merchant Marine

Rapidly approaching full-scale peacetime production, marine-turbine and gear factories of the General Electric Company are now furnishing propulsion equipment for 42 ships of America's post-war merchant fleet and for 20 Brazilian ships, it was announced by the G-E Federal and Marine Divisions.

In contrast to the wartime policy of building merchant ships to uniform design, the new vessels will have many innovations wanted by the owners to meet varied operating conditions, R. S. Neblett, G-E Federal and Marine manager, explained. He also revealed that during the war the company's marine-turbine factories produced more than 40 per cent of the merchant ship propulsion equipment.

Turbines and gears are being supplied for 22 ships which represent part of an extensive reconstruction program by Lykes Brothers Steamship Co. Seventeen of these 22 ships are C-2 6000-horsepower vessels of 9600 deadweight tons, from the yard of the North Carolina Shipbuilding Co., Wilmington, N. C. The last of these are nearing completion. During the war years this yard produced 117 C-2 vessels with G-E propulsion equipment.

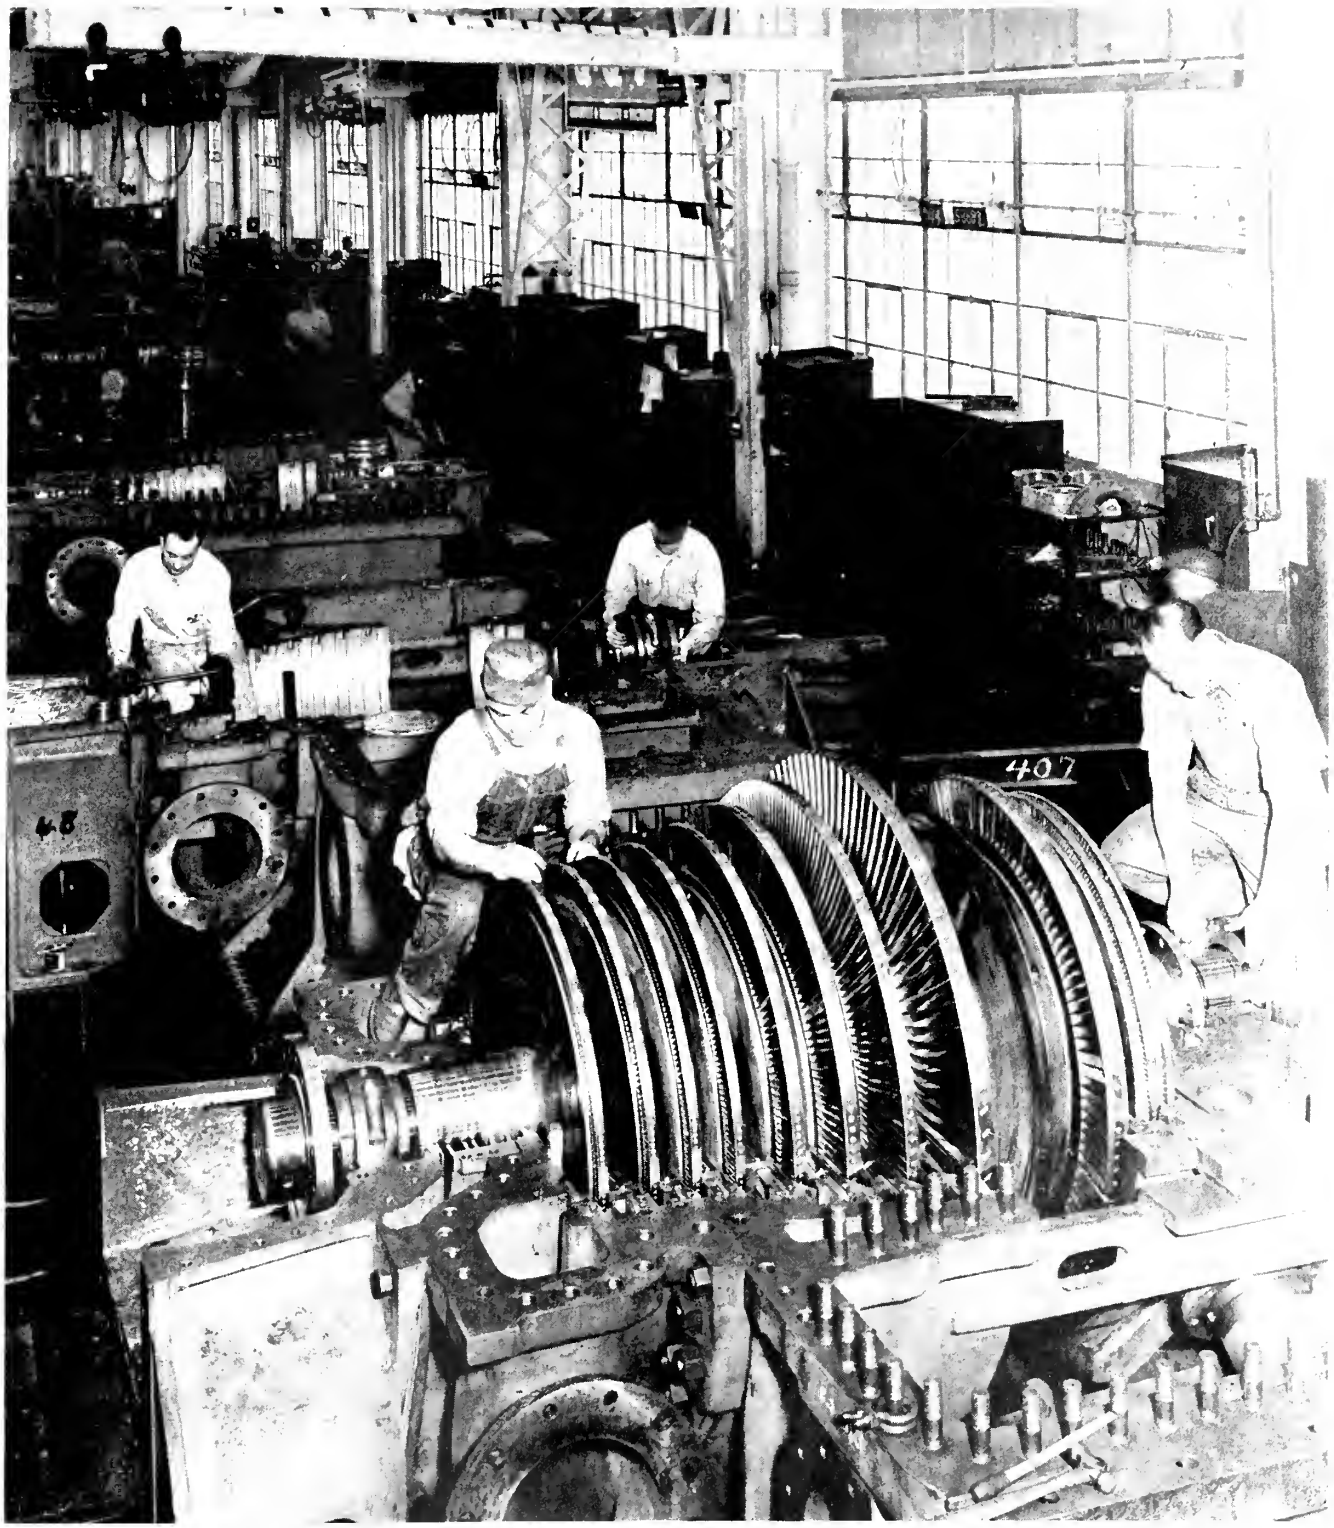
Designed for Lykes Brothers' Far Eastern service, five C-3 ships of 12,800 deadweight tons, with 8500 horsepower turbines and gears, are being designed and built by Federal Shipbuilding and Drydock Co., Kearny, N. J. The first of the group, the Tillie Lykes, recently completed trial runs. The remaining four will be delivered within the next few months. "They have many characteristics that should make them the finest and fastest cargo vessels in the Pacific," J. T. Lykes, president, said in announcing the line's post-war plans.

Six more C-3 vessels, wth 8500-horsepower turbine-gear propulsion, are being completed at the Federal Shipbuilding yards for the American South African Line for service between the Americas and Capetown.

Further additions to the post-war merchant marine are nine C-2 ships for the South American service of the Grace Lines. Six of them are nearing completion at the North Carolina Shipbuilding yards and three at the Federal Shipbuilding yards. Three new-type passenger-cargo ships of the C-3 class are being constructed at the Ingalls Shipbuilding Corp., Pascagoula, Miss., for the Caribbean service of the Mississippi Shipping Co. George G. Sharp is the naval architect.

Two high-speed single-screw tankers, to have 5000-horsepower turbine-gear propulsion, are being designed and built at the Sun Shipbuilding and Drydock Co., Chester, Pa., for the large fleet of Standard Oil Co. of California.

Brazil's Lloyd Brasileiro has contracted for 20 ships with 6000-horsepower turbine-gear propulsion of General Electric design. Fourteen of these vessels are being built at the Ingalls yards and six at Canadian Vickers, Ltd., Montreal. George G. Sharp is the naval architect.



Rapidly approaching full-scale peacetime production, marine-turbine and gear factories of the General Electric Co. are now furnishing propulsion equipment for 42 ships of America's postwar merchant fleet and 20 for Brazilian ships, it was announced by the G-E Federal and Marine Divisions. In the photo, workers in a company turbine factory are assembling a marine turbine. Steam at high pressure hits the turbine wheels, turning the turbine shaft. Through gears, the propeller shaft is rotated.

Puget Sound Navy Yard

By Robert N. Ward

Rear Admiral Ralph W. Christie, U.S.N., commandant, United States Naval Base, Bremerton, Washington. (Official U. S. Navy Photograph).

THIS IS A SORT OF Horatio Alger story—the career of a Navy Yard that started during the nineties of last century as a tidal marsh full of swamp grass and gradually became an important link in the repair units taking care of the Pacific fleets of the U. S. Navy. Then suddenly in World War II it grew up to break record after record as one of the Navy's outstanding repair bases.

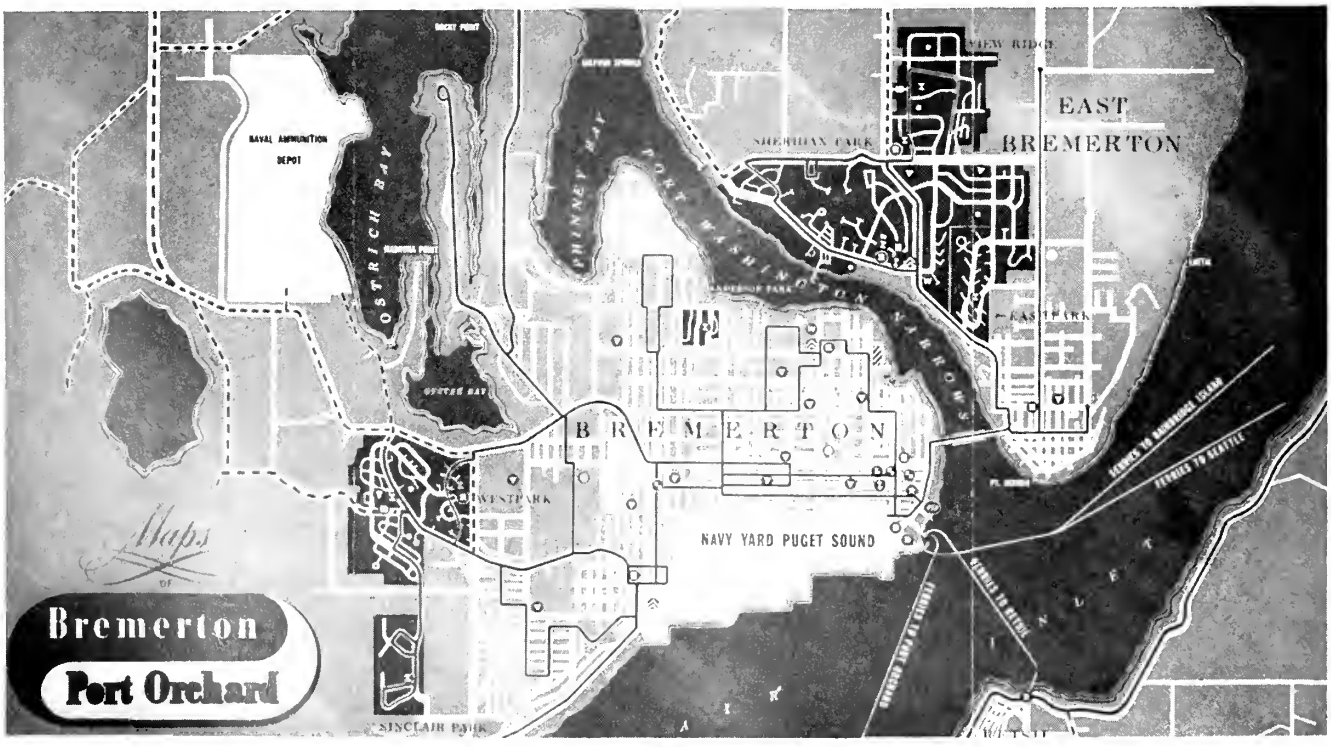
When the war began Puget Sound Navy Yard at Bremerton, Washington, was one of the smallest such bases maintained by the Navy. And even its wartime expansion did not match that of the Navy's already larger bases farther south on the Pacific Coast.

Instead, the Puget Sound yard turned to specialization in repair—the mending of battle-damaged fighting ships. And before the war ended PSNY had established a fleet-wide reputation as one of the "hottest" yards in the nation.

Easing of naval censorship now allows the enviable war record of the Puget Sound Navy Yard to be told.

During the war 344 fighting ships of all types, including five of the battlewagons blasted at Pearl Harbor, were repaired, overhauled or modernized there. This was in addition to 45 ships built—destroyers and smaller craft—and five escort carriers fitted out.

The yard also instilled its "know-how" in the many men it trained for the Navy's Ship Repair Units. In the combat zones SRU men worked un-



U. S. Naval Base at Bremerton, Washington. Taken from 3500 feet above Sinclair inlet, looking north, view shows four of large graving docks busy. Note floating drydock in graving dock No. 1, at right. Main section of Bremerton, center and right, is separated from East Bremerton, right background, by Port Washington Narrows. Supply and quarters section of base is left and center foreground. (Official U. S. Navy Photograph)

der fire many times to fix the Navy's "cripples."

It got to be almost routine for PSNY officials to set what appeared to naval chiefs in Washington to be impossibly fast schedules for repairing major fleet units—and then beat the schedules.

The huge aircraft carrier Saratoga, one of the most heavily-damaged ships of the war, was repaired at PSNY in record time. The job won for the yard a commendation from Vice Admiral E. L. Cochrane, chief of the Navy Bureau of Ships.

When the cruiser Pittsburgh lost 104 feet of her bow in a Pacific theater typhoon, PSNY officers looked over damage reports and offered to fix her in 42 days. Next shortest time estimate was 110 days. The Pittsburgh came to Puget Sound.

Four admirals commanded the yard during the wartime years, when it reached its high peak of repair efficiency. When the war began Vice Admiral C. S. Freeman was commandant. He was succeeded by Rear Admiral S. A. Taffinder, who was followed by Rear Admiral R. M. Griffin.

Present chief is Rear Admiral Ralph W. Christie, Navy submarine expert. Admiral Christie was yard commandant when the end of the war brought organizational changes. He now commands the Bremerton Navy Base, new name for the yard combined with other Navy activities in the area.

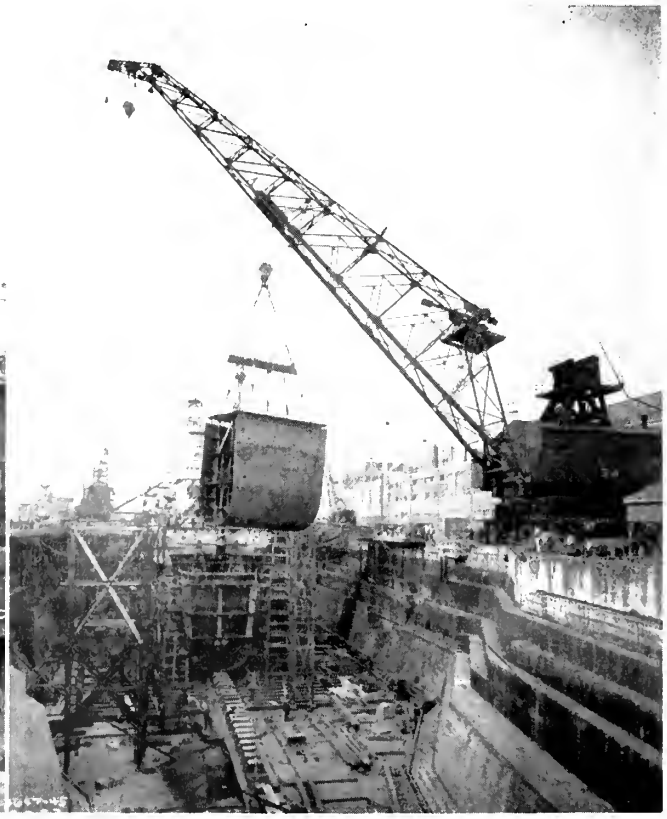
The yard portion of the base, now called the Puget Sound Naval Shipyard, is commanded by Commodore W. M. Thompson, former production officer at the Norfolk Navy Yard. Captain Paul B. Nibecker is yard production officer.

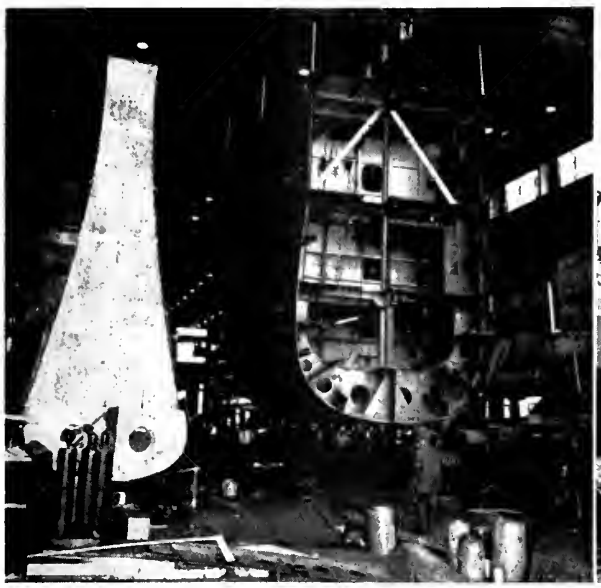
Under the press of war, commanders and engineering personnel of PSNY invented and developed special rush repair methods.

Some of them were pretty drastic. Many a skipper during the war watched, perplexed, as repair crews

Slung from a traveling crane, one of the Pittsburgh's huge bow sections moves to the drydock. (Official U. S. Navy Photograph).

The second new keel section for the Pittsburgh is swung into the drydock. Machinists, pipefitters and electricians already are working inside the first one. (Official U. S. Navy Photograph).





New bow sections for the battered Pittsburgh go together rapidly in one of Puget Sound's prefabrication shops. Most of this work was done while the cruiser still was at sea. (Official U. S. Navy Photograph).

Final keel section goes into place on the Pittsburgh. Communications, piping and wiring are already installed in the previously-fitted portions. (Official U. S. Navy Photograph).

attacked his ship with the seeming intention of dismantling it completely.

In fixing a destroyer that had been twisted out of line, engineers ordered the craft cut almost in two. Burners slashed from the keel upward to, but not through, the deck. The two sections were then straightened separately and welded back together.

One of red-headed, energetic Captain Nibecker's tricks is to cut great sections from the outer shell of a ship to get at difficult places or move heavy machinery in or out of a ship's vitals.

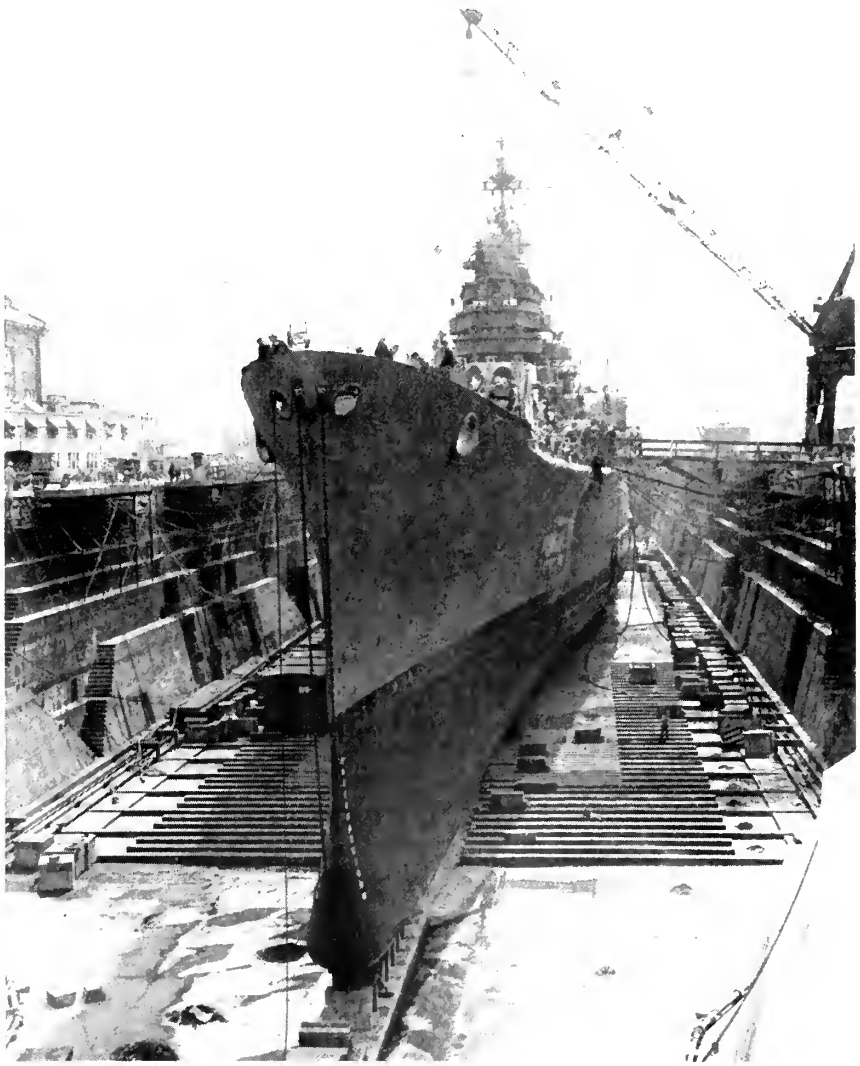
"Captain Nibecker," says Admiral Christie somewhat wonderingly, "will cut a hole anywhere he needs it!"

By doing this, the yard saved five days in repairing the destroyer Lamson, "kamikazed" during the fight for the Philippines. Large holes were cut up through the bottom plates of the craft. Through these, work crews removed debris and heavy equipment that otherwise would have had to be hoisted, a bit at a time, through small deck openings.

New methods helped set the record the yard made in repairing the Saratoga. Her balsawood docking cradle was designed to confine oil to a small area. This saved 100-man-days dock cleaning.

Yard workers cut three huge holes in the Sara's sides. They erected a stairway from the dock floor to her flight deck. An information center, installed in the hangar deck, kept

Complete! Here's the Pittsburgh's sleek new nose. The last section was welded on just three weeks after the first one, ahead of a record repair schedule. (Official U. S. Navy Photograph).



Seconds after a big carrier finishes docking, crane swings portable telephone exchange to flight deck for crew to call homes. Four telephone operators are inside—and are they welcome aboard ship! (Official U. S. Navy Photograph).

workmen from getting lost—literally—in the Sara's complicated compartments.

Vast areas of the Sara below-decks had been blackened by flame and smoke. Yard workers used sandblasters to clean up. But to sandblast they added a spray of water. This process, perfected in the yard paint shop, eliminated flying dust dangers.

These short-cuts saved more than 3000 man-days of labor and thousands of dollars on that one job alone.

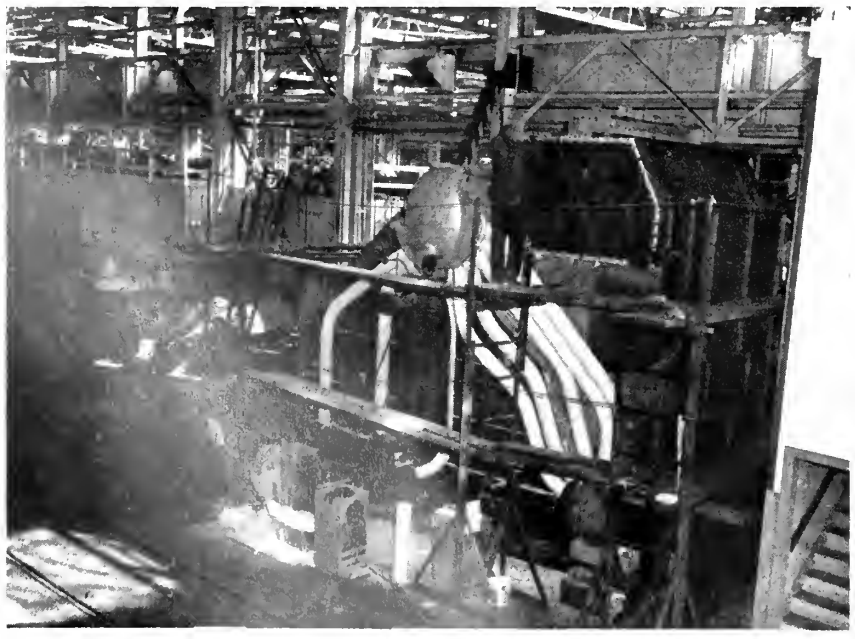
Repairing done on the Pittsburgh is a good example of the prefabrication technique which helped Puget Sound set records. When the job was awarded, engineers began immediately gathering more than 500 plans of the ship from other shipyards on both coasts.

From a preliminary radio report of the damage, engineers laid the groundwork for constructing new bow sections. An officer of the ship was flown from the Pacific to PSNY with more details and photographs.

The crippled Pittsburgh, with a blunt, thin steel jury bow welded on, started her 5000-mile trip home.

Meanwhile, the yard did all the preliminary work. In the shipfitting shop, 300 tons of steel were prefabricated. The new bow was built in eight sections and moved by traveling crane to dockside. All material and shipping tags were marked with red. The Pittsburgh was "hot."

A 10,000-horsepower boiler is overhauled in the boiler shop. One of four is the U.S.S. Charles J. Badger, a destroyer; boiler had casings collapsed as a result of a crash of the Jap suicide boat off Okinawa. (Official U. S. Navy Photograph).



The job of assembling numerous items, from all parts of the country, went ahead. Along with her bow, the cruiser had lost anchor gear, mooring equipment, capstans, water pumps, anti-aircraft guns, ammunition magazines, staterooms and storerooms containing 80 per cent of the ship's spare parts and supplies.

At Port Angeles, 80 miles down-Sound from the yard, engineers met and boarded the cruiser. It meant saving six vital hours. So, while the Pittsburgh churned along at 12 knots, PSNY experts checked their preliminary work against actual damage.

At the yard, the cruiser was rushed into a graving dock. As the chamber was pumped out burners cut off the jury bow, working bare inches above the receding water.

The preliminary work had been so thorough that the first new bow section was swung into place a few days after drydocking. As each section was welded on, pipefitters, machinists, painters and sheetmetal men swarmed through it. Three weeks later the final bow section was welded in place.

The war ended suddenly, while

the Pittsburgh was in dock. And the pressure eased off. But up to that time the work was ahead of schedule—the fastest schedule offered by any yard.

By methods like these the yard fabricated and installed 73,116 tons of steel in fighting ships during the war. Total tonnage of ships handled, in all types of work, was 3,467,677.

The yard labor force was 3189 one year before Pearl Harbor. At its wartime peak in August, 1945, it stood at 33,141.

All this was a far cry from the yard's beginning little more than 50 years ago. The Navy acquired a site on Sinclair Inlet in 1891 to establish a naval repair station there.

First commandant was Lieut. A. B. Wyckoff, who arrived in a small gunboat and found his new command to be a swamp full of willows and marsh reeds.

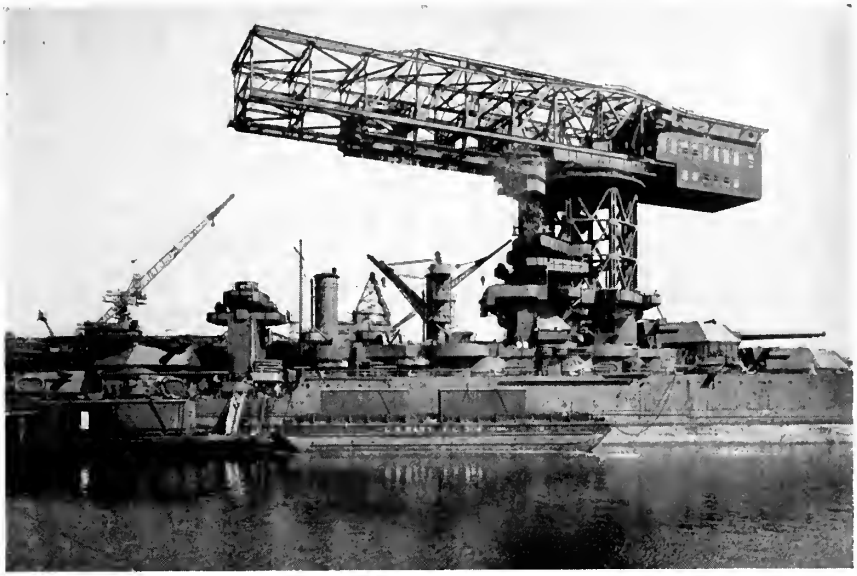
Next year work was begun on a drydock built of piling with stone sill and gateposts. Completed nearly four years later, the dock was 650 feet long, 130 wide at the top, 67 feet across the bottom and 39 feet deep—largest naval drydock in the country at the time.

First ship to be docked there was the USS Monterey. Later the early-day Iowa, of "Teddy" Roosevelt's Great White Fleet, was blocked up for overhaul. The famed Oregon was in this dock for overhaul in 1900 and came in for modernizing and was recommissioned in 1915.

There still is a drydock on the site—a modern concrete structure. But now there are four more, larger ones whose dimensions the Navy classes as restricted, plus a couple of floating drydocks. Bremerton can dock the largest ships in the Navy.

Much of the yard's equipment is outstanding or unique.

On one of the six giant piers is one of the world's largest roller circle, turntable type, revolving hammerhead cranes. Its capacity is 250 tons and it can operate to capacity in a 40-mile wind. The monster is 175 feet high, but is operated by one man.



Largest of its type in the world, this roller-circle, turntable type crane can lift 250 tons in a 40-mile wind. It's on the yard's Pier 6. (Official U. S. Navy Photograph).

The yard's inside machine shop, measuring 1080 by 310 feet, is claimed to be the largest west of the Mississippi. Biggest tool in the shop is a 60-inch lathe, 195 feet long, on which may be finished propeller shafts for our largest fighting ships.

Another feature of the base is one of the world's largest single air raid shelters. It is a four-entrance tunnel, with 2200 feet of passageways, dug into the hill behind the yard. Capacity is 10,000 persons. Equipment was stored there late in the war.

One special service is deeply appreciated by crews of incoming ships. Minutes after a vessel docks for repair, a large portable telephone exchange is swung aboard by crane. Inside are booths and four operators who command direct lines to the East, Midwest and South. Sailors call home from their own deck.

To the yard goes sole credit for increasing the population of Bremerton fivefold in the past five years. A one-industry town, Bremerton had a population of 15,134 in 1940. Now it is estimated at between 72,000 and 80,000.

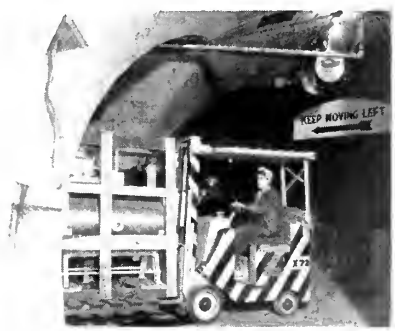
Bremerton had no railroad until last year, when the Navy decided that rail connections were vital to the yard. So the Navy built a standard gage line to a Northern Pacific track 36 miles south. It was a rush job, and expensive, averaging about $200,000 per mile.

The boom in Bremerton began in 1940, when America's defense program began to increase in tempo. In a year employment at the yard increased 500 per cent. Shipbuilding was the yard's job that year, and destroyers and escort ships went down the ways in increasing numbers.

Then one day in September, 1941, a great, gray capital ship nosed its way through morning mists and into Sinclair Inlet. Shoreside observers, familiar with the silhouettes of American battleships, were baffled.

Months later the secret came out. The newcomer was the British battleship Warspite, which had taken a beating from dive-bombers in the

When danger of air raids passed, in late stages of war, goods were stored in the giant air raid shelter, buried in hill behind base. The tunnel is designed to hold 10,000 persons. (Official U. S. Navy Photograph).



battle of Crete. She had limped three-quarters of the way around the world, from Suez east to Bremerton, for repair.

The Warspite had taken a bad bomb hit in the crew's quarters forward, with many casualties and extensive damage. At PSNY she got repairs, more armor, and boiler and communications alteration.

That was the Puget Sound Navy Yard's first big naval repair job, and the start of a new type of work for the base. For after the Warspite came the first of five grim, fire-blackened battlewagons from Pearl Harbor.

The Tennessee and the Maryland nosed into graving docks at Bremerton the last of December, 1941. They joined the fleet 53 days later. And PSNY moved into the big time.

Next in was the Nevada. She took seven months and 700,000 man-days to put her back in shape. But her new guns were ripping up the Normandy beaches one fateful day two years later.

Finally came the California and the West Virginia, most heavily damaged Pearl Harbor ships to return to the mainland. It had taken 18 months to raise them and get them home.

But before then the future of PSNY already was decided. The "old ladies" of the fleet came to Bremerton in bad shape. From the first, the yard did an outstanding job. And when the first of the battlewagons left they were more modern, better protected and had vastly-increased fire-power.

The job done on the "old ladies" impressed the Navy's braid. A few months later the Puget Sound Navy Yard was ordered to concentrate on ship repair.

Pictures taken at Puget Sound Naval Station in 1900. Reading down, they show ship carpenters, the Station, officers' quarters, and office employees.

The Fighting Diesel

THE OMINOUS offshore roar which warned both Hitler and Hirohito that their hour of doom was at hand came not only from airplanes but also from the mighty throb of tens of thousands of diesel engines.

Our final victory was the terrible climax toward which, for over four years, an ever-increasing torrent of power had been flowing from three great General Motors plants—the Cleveland Diesel Engine Division, the Detroit Diesel Engine Division, and the Electro-Motive Division.

For where the war went, diesel was there first. To conquer islands or continents, we must have landing craft, thousands upon thousands of them—little ones, big ones, to put our troops on the beaches and keep them there. And diesel did that, and more, in World War II.

But far beyond the beachheads went diesel engines. They powered submarines and submarine mother ships; SC subchasers, 131 and 171-foot PC subchasers; DE destroyer escorts, minesweepers, rescue vessels; tankers; diving tenders; landing boats and barges; tank and cargo lighters; dredges, tank and tank destroyers; tractors and bulldozers; shovels; standby and portable generator sets; dock compressors; lighthouse service; buses and trucks. So enormous was the output that by October, 1943, total diesel power passed the total steam power used by the U. S. Navy.

Before the war, General Motors was building a series of two-cycle engines with from two to six cylinders. Into these standard packages of power had been built unique features of engineering design which were destined to play an important role for the armed forces: The low weight factor of a two-cycle diesel was ideal for many military uses.

Then came war. Mass production of diesel power plants in the most efficient manner already was in existence. Stepping it up to meet the incredible needs of total war was a matter of shrewd management in increasing production facilities.

First the cry was for tanks. They were supplied, and fought gallantly during the critical days of the war in Egypt. Then the furious attempt of the Axis army to reach the Nile was repulsed. Our diesel tanks stood up at Alamein, finally smashing through the Axis defenses and joining the Allied forces from Algiers in the final drive on Tunis.

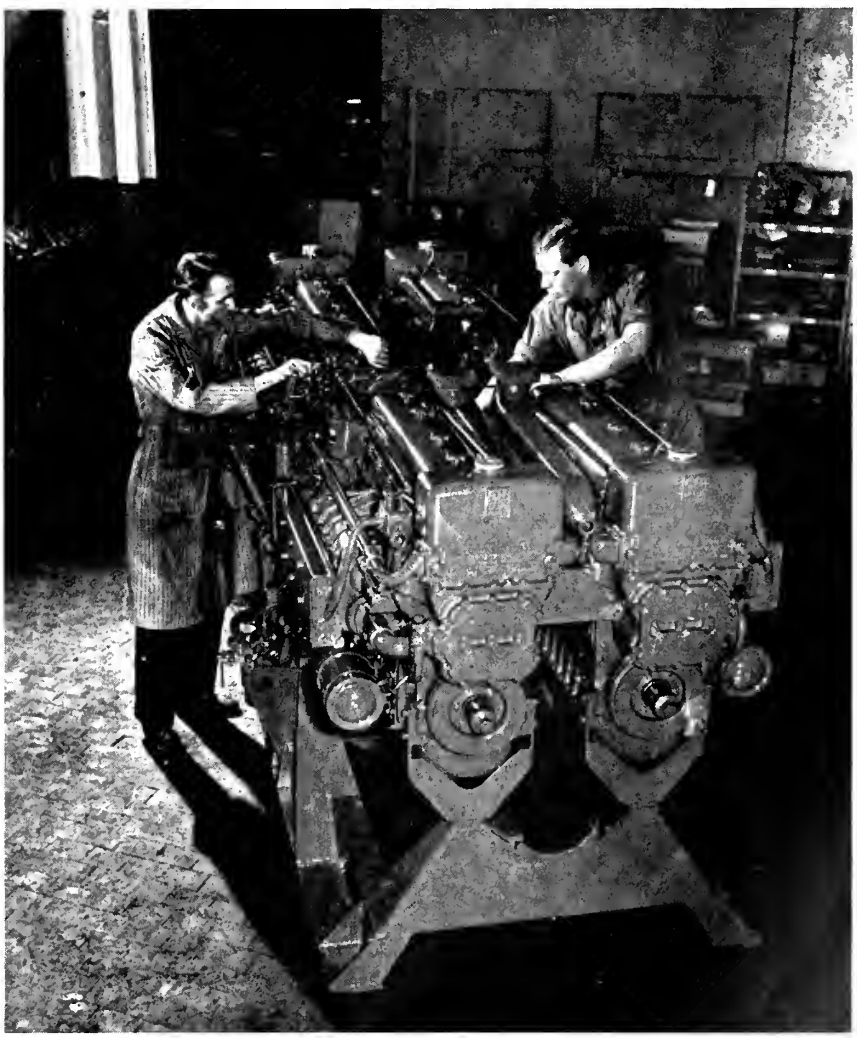
Diesels were used in small landing craft during those dark days—the LCVP (Landing Craft Vehicle Personnel) powered by one six-cylinder engine, and in the LCM (Landing Craft, Mechanized) powered by two six-cylinder units, and the LCT (Landing Craft, Tank) by three units. Each unit had its own propeller shaft, and the units could be operated individually or together.

The ability of this type of craft to extricate itself easily from the beach by a miniature erosion with its wash, together with a winch on the stern, was extremely valuable in mass transportation of troops.

These boats had pre-war engines of 165 horsepower but were stepped up to 225 horsepower. But this was only the beginning. Diesel engines were destined to play an ever increasing role in World War II.

Busy engineers at the Cleveland Diesel Engine Division and the Detroit Diesel Engine Division of General Motors hit upon a basic design of two to six cylinder engines. Most of their parts were interchangeable, engine for engine, cylinder for cylinder. Reciprocating parts such as pistons, connecting rods and valves, were interchangeable. And vastly im-

The Quad, new diesel power plant for various U. S. Navy landing barges, developed by Detroit Diesel Engine Division of General Motors.



A General Motors diesel engine being installed in an M-4 tank in a Fisher Body plant which produces America's newest type of land fighter.

GM diesel motive power for the famed M-4 and M-10 tanks being installed by Army mechanics.

portant was a symmetrical cylinder block permitting right-or-left-hand rotation with accessories on either side. This feature permitted the coupling of two basic engines by means of a transfer case to deliver the double power to a single driveshaft for the "Twin" Series 71 engine.

Consisting of a pair of 6-cylinder engines placed side by side, this unit joined exhaust manifolds, essential accessories, including blowers, fuel pump, water pumps, oil coolers, air cleaners, secondary fuel oil filters and governors—all on the exterior. A heavy junction plate joined the engines at the front end and a double clutch housing and gear unit at the flywheel end. Each engine had its own fuel, lubrication and water cooling systems.

Thus did diesel horsepower move into space originally designed for radial air-cooled gasoline engines in the General Grant (M3) tank the General Sherman (M4) tank, and the M10 Tank Destroyer.

Still more feverishly did General Motors engineers work, finally surpassing the "Twin" diesel in the now famous "Quad." This combined four six-cylinder diesels with two "Quads" powering each LCI. Each "Quad" developed 900 horsepower and had its own gear box, propeller shaft and propeller with variable pitch control. The weight was only about 12.5 pounds per horsepower developed.

The peacetime uses of both the "Twin" and the "Quad" are numerous. For example, in the fishing industry, the 20-foot boat to the 150-foot tuna clipper could utilize unit engines, singly or in multiple combination. If one engine failed, it could be immediately "cut out," the others permitting the ship to finish its catch and return. Already this multiple type engine is being installed commercially.

And these multiple high speed engines are far from short-lived. They have crossed both the Atlantic and the Pacific, giving thousands of tough hours with negligible service requirements. Every landing craft must be capable of hitting a beach hard, dumping its cargo and quickly pulling away, even with breakers running high.

That diesels achieve these punishing requirements admirably is exemplified in the following message typical of many to the workers of the Detroit Diesel Engine Division from Rear Admiral E. L. Cochrane, Chief of the Bureau of Ships, USN. Re-

ferring to the two-cycle 71-series GM diesel Admiral Cochrane wired:

"You will be gratified to know that a large majority of the invasion vessels which participated in the Sicilian campaign were powered by your diesels. That this largest invasion operation in history was executed with a maximum of precision and a minimum of casualties was in no small measure due to the reliable power plants supplied by you for our assault craft. All of you are to be warmly commended for your contribution to the victory."

And Vice Admiral R. R. Waesche, Commandant, U. S. Coast Guard, in an expression to the workers of the Cleveland Diesel Engine Division, wired:

"It will be a source of great pride to you that your Winton Marine Diesel Engines, Model-158, were in operation on the U. S. Coast Guard Cutter Icarus when she sank a German submarine and captured 33 members of her crew."

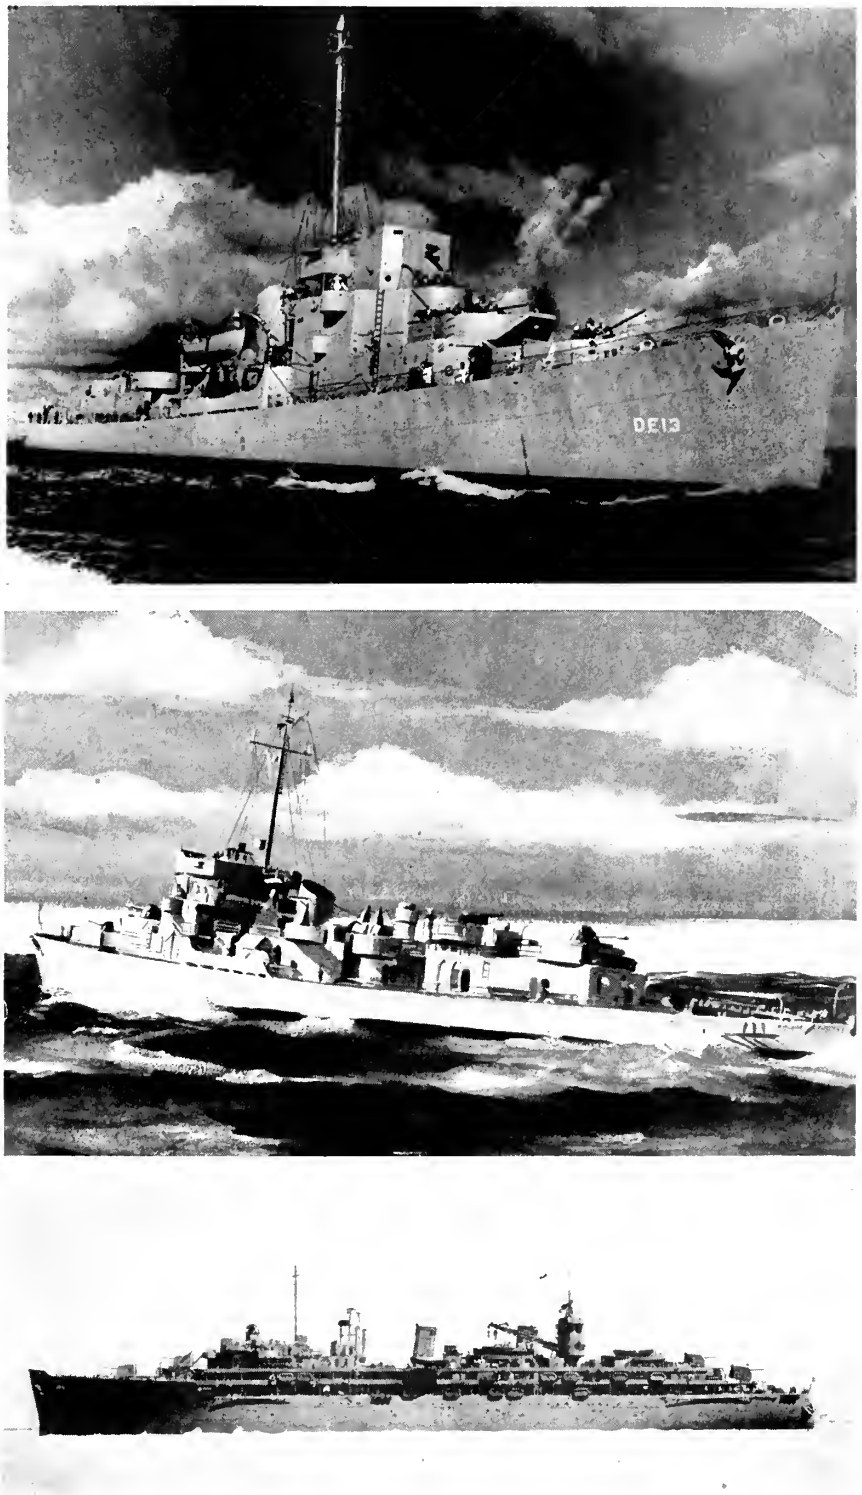
In quoting a communique from the Icarus' skipper concerning the ship's performance in combat, Admiral Waesche wired:

"Our engines worked perfectly throughout the action. They responded immediately to every demand. All our attacks were carried out at full speed, and our fourth pattern of charges blew the sub to the surface. We closed in with all guns firing. In four minutes she went down."

From another East Coast operating base, Admiral Waesche reported this comment:

"In spite of the fact that we ordinarily feel that an engine should be overhauled after 3000 hours' operation, our Winton diesels frequently have operated for over 4500 hours without the slightest trouble. To you who are producing these reliable engines, the Coast Guard extends commendations and thanks. We need more of them."

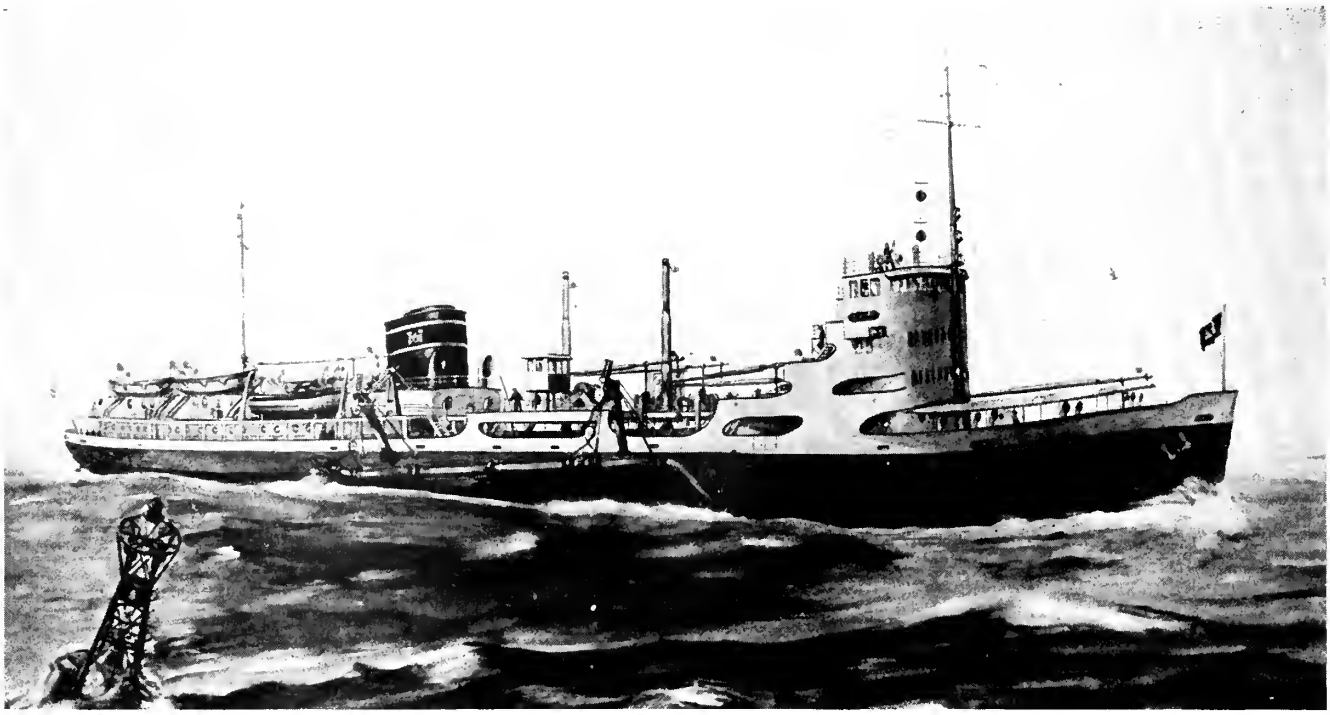
Matching the speed, the skill and ingenuity of manufacturing at the Cleveland Diesel and Detroit Diesel Divisions of General Motors were the extraordinary accomplishments of service representatives of the diesel industry. In Army and Navy camps, bases, arsenals, shipyards and installations in the U. S., and from the Aleutians to Australia in the Pacific, and Iceland to Africa and Europe in the Atlantic; on fighting fronts on land and sea the world around, these service men stayed on the job, assisting and teaching Army and Navy mechanics to "keep 'em running."



Top: One of Uncle Sam's Destroyer Escorts, powered by G-M diesels, knifes through the water in a trial run. (Official U. S. Navy Photograph). Center: A Destroyer Escort vessel powered by General Motors diesels. Bottom: Submarine Tender U.S.S. Sperry, powered by Cleveland diesel engine.

Today the fighting is over. Diesel did a job. GM diesels were selected by the armed forces for landing craft and other essential power operations because without any required changes they met the high standards of the military.

But diesel engineers are not relaxed. They still dream and figure and experiment on greater achievements to come. New adventures lie ahead. Today people everywhere are discovering that there occurred during World II an amazing revolution in the world of mechanical power.

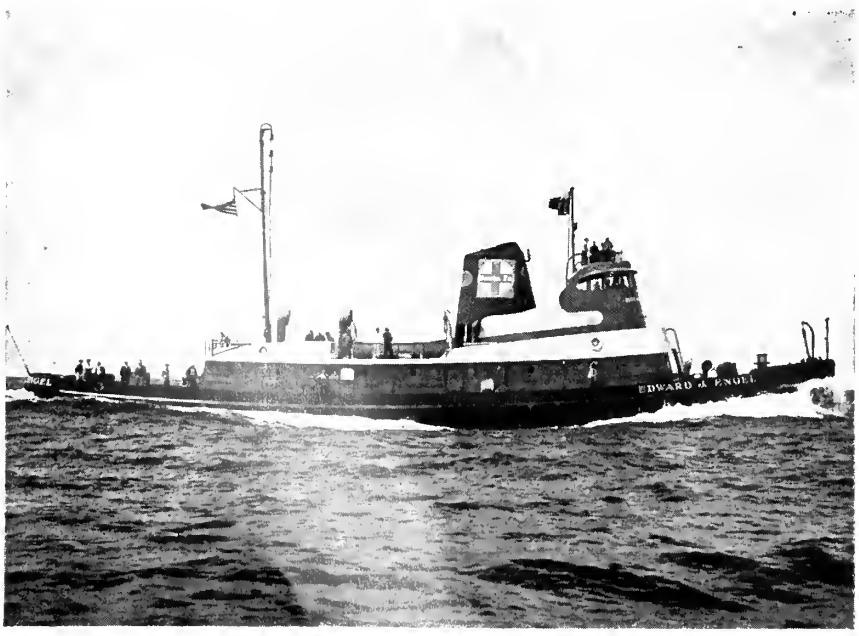


352-foot seagoing hopper dredge.

Coast Design Firm's Wartime Record

Joslyn & Ryan Planned Many Ships

142-foot tugboat for Santa Fe Railroad.



The emergency resulting from the prosecution of war by the United States against our enemies in the European and Pacific areas has come and gone, but the complete story of what happened during these years to bring about the tremendous production of arms, war plants, ships, products and equipment of every conceivable nature still remains to be told, to a great degree. It is true, the people of the nation were informed continually of the urgent necessity of mobilizing every resource of man power and materials, and were spurred on to greater activity by the release of censored information from time to time regarding the vast developments of shipyards and other industrial achievements.

Much interesting information could not be told for security reasons, and as each super activity superseded another a great deal of the story

concerning the stupendous effort exerted by industry and labor alike remained untold, in order that our goal be not endangered.

The Pacific Coast was called upon to furnish a large portion of the war materials required, particularly ships for the Pacific area. Firms of long standing were compelled to increase their facilities and output many fold. New firms came into being overnight and added their contribution to the total effort. Many of these have ceased to exist, now that the emergency is past.

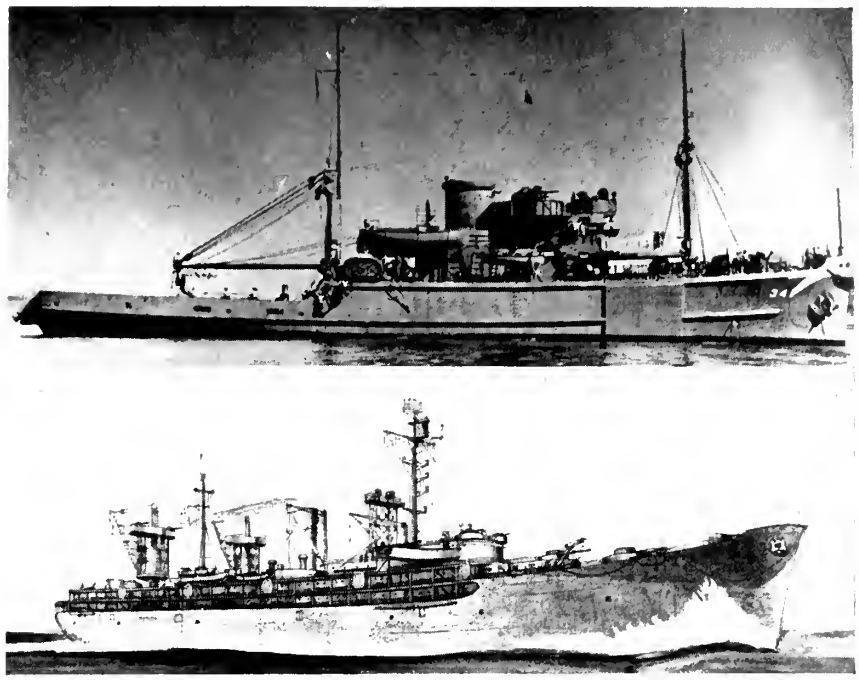
One of the concerns, established before the war, and of particular interest to shipping men up and down the Pacific Coast, and one that is destined to grow in importance, is the firm of Joslyn and Ryan, Marine Engineers and Naval Architects, 149 New Montgomery Street, San Francisco, who turned out thousands of plans for a great variety of ships built for our maritime and naval operations.

Ship designs were furnished by this firm for vessels built by shipyards from one end of the Pacific Coast to the other, as well as in Atlantic and Gulf ports. Joslyn & Ryan expanded its force of draftsmen and clerical personnel to a total of over 550 employees, which represented an increase of ten times their pre-war size. They are the largest organization of this nature on the Pacific Coast, as well as being one of the outstanding designing firms in the nation.

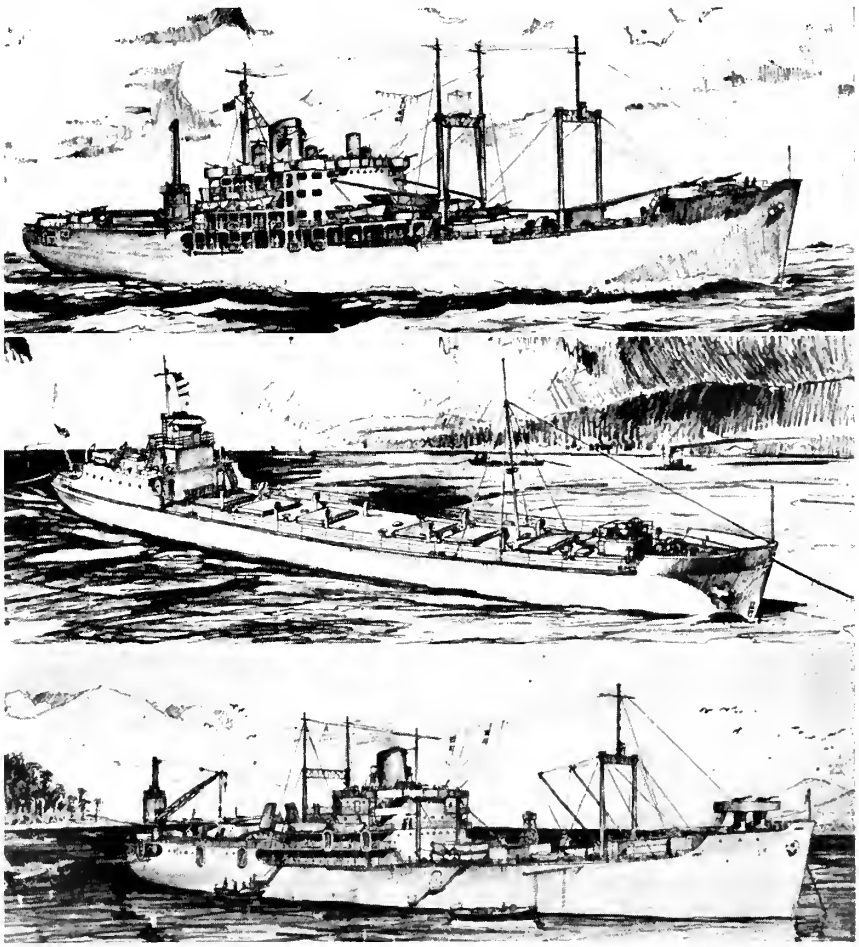
The firm is headed by Paul L. Joslyn and Michael J. Ryan, both of whom have been identified with shipping and shipbuilding interests in this area for many years.

Paul L. Joslyn is well known in the marine engineering field on the Pacific Coast, and for many years has been engaged in the design of ships and their power plants, both steam and diesel. He pioneered the first marine turbine installations on the Coast, both for cargo and tank vessels, in 1913-14, while serving as chief engineer at the Bethlehem Steel Company (Union Iron Works Plant) in San Francisco, and later at the Moore Dry Dock Company in Oakland.

Some time prior to the Pearl Harbor attack Joslyn founded the present firm when he accepted the contract from the Williamette Iron and Steel Corporation to handle the conversion of the former transatlantic liners City of Baltimore and the City of Norfolk into naval transports.



Top to bottom: Salvage vessel; AD-16 destroyer tender; AV 14-17 seaplane tender; concrete barge; AV 10 seaplane tender Chandeleur.



Michael J. Ryan majored in Naval Architecture and Marine Engineering at Massachusetts Institute of Technology. His early training was obtained at the Union Iron Works, and during the first world war he was assistant Naval Architect at the Moore Dry Dock Company in Oak-

Paul L. Joslyn

land. Between 1930 and 1932 he was Technical Surveyor for the American Bureau of Shipping in the Plan Approval Section. He specialized in tonnage measurement requirements for the Panama and Suez Canals, and acted as consultant with regard to these requirements on vessels of many foreign and domestic shipping companies, including the United States Lines, Dollar Steamship Line, and Luckenbach Line.

Ryan became associated with Joslyn in the present undertaking on the contract for the design work on the U. S. Navy fuel oil tanks built by the Basalt Rock Company of Napa, California, and the Lake Superior Shipbuilding Company of Superior, Wisconsin.

The company's staff is composed of experienced marine engineers and shipbuilders, and other engineering personnel, all capably supervised by: E. Mitchell Breingan, chief naval architect; J. H. Laidman, assistant naval architect and estimator; J. C. Hare, in charge of hull materials; S. A. Lindsay, in charge of ventilation; James B. Bouick, Jr., chief marine engineer; and D. D. Howell, planning engineer.

Michael J. Ryan

First Luxury Liner—The Del Norte

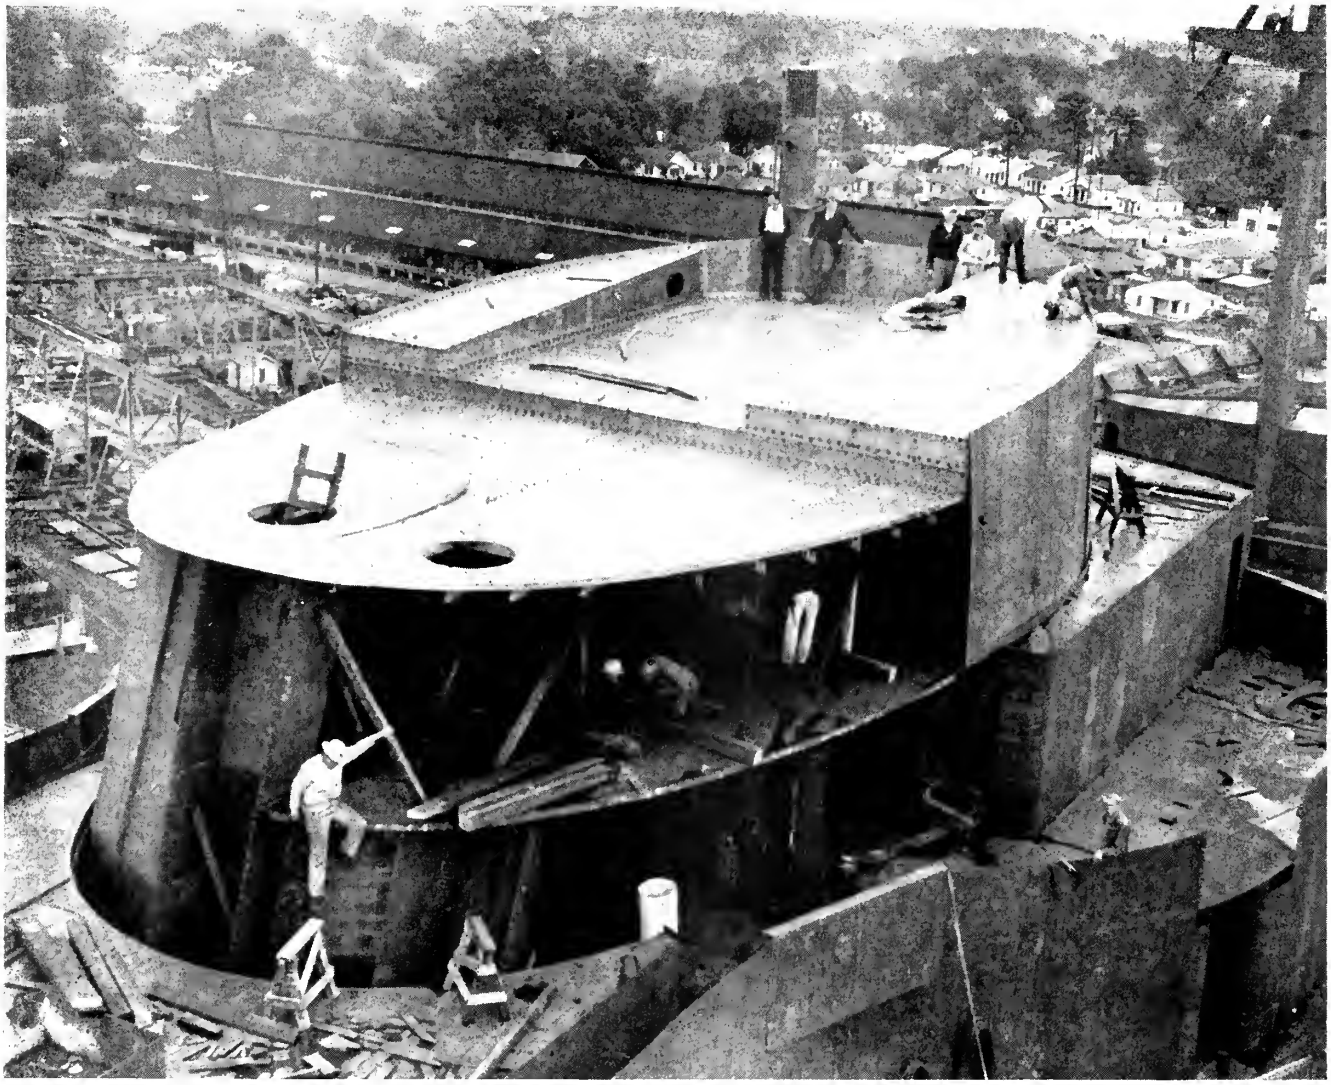
Aluminum Stackhouse, Lifeboats, Davits and Gear

THE NATION'S FIRST luxury liner to be built since the war was launched on January 11 at the Pascagoula, Miss., yard of the Ingalls Shipbuilding Corporation.

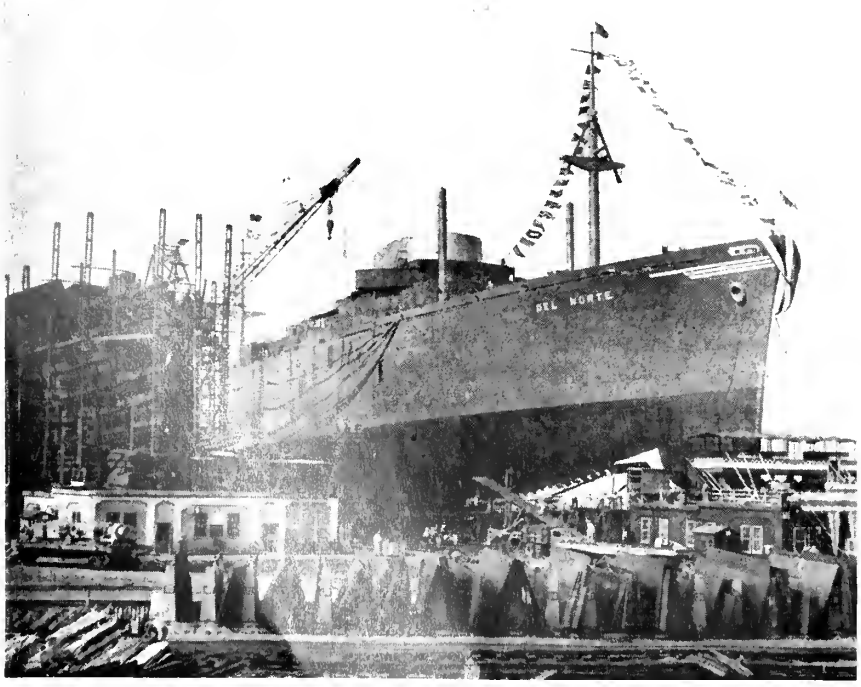
Featuring an aluminum stackhouse and the latest war-developed navigational aids, the 17,000-ton Del Norte is scheduled to make her maiden voyage on the South American run this spring for the Mississippi Shipping Company's Delta Line. She is one of three identical ships now being constructed at Ingalls for Delta.

In addition to aluminum plate and

The sprawling Ingalls shipyard at Pascagoula, Miss., was busy an ships in all stages of construction when this aerial view was taken recently. The yard, with $100,000,000 in peacetime ship orders, is looking for new employees.



Above: The Ingalls-built Del Norte's aluminum stockhouse is used as a deckhouse, inside of which are emergency generators, batteries for the same, chart room and wheel house. The upper level will be used for living rooms for radio operators and the radio office. Close to 75,000 pounds of aluminum alloy and cast aluminum are in the Delta Line ship, representing a saving of one pound in displacement for each pound of aluminum used.



With scaffolds removed and bunting flying, the 17,000-ton Del Norte stands poised on the ways for launching. Complete, she will represent an expenditure of about $6,000,000. Her gleaming aluminum superstructure may be plainly seen.

structural members in the stackhouse, aluminum is used in the vessel's lifeboats, davits and gear. In all, close to 75,000 pounds of aluminum alloy and castings go into the ship, representing a total saving of approximately the same weight in displacement.

The elliptical-shaped stackhouse is false, and is used instead to house emergency generators, batteries for the same, chart room and wheel house. On the upper level are living rooms for radio operators and the radio office. Exhaust gases from the boilers escape through separate smoke pipes aft of the stackhouse.

Aluminum alloys are also used extensively in extruded moldings for

grills, stair balusters, rails and other decorative applications.

Designed by George G. Sharp, naval architect of New York, the all-welded Del Norte is a modification of the C-3P in design. She is 489 feet in length, 69½ feet in breadth, with a depth of 45½ feet. She is the first and finest of her type.

The ships are designed to provide passenger accommodations exceeding those of pre-war luxury liners, and they are equipped with the most modern cargo-carrying facilities.

The three ships, which will be built at a total cost of more than $16,000,000, will be air-conditioned throughout, being the first passenger-cargo vessels to have this feature for all aboard, including the crew.

For the convenience of the 120 passengers, the Del Norte features a glass-enclosed promenade, outdoor swimming pool and sundeck, cafe and bar, grand salon and library, midship passenger elevator and a modern shopping center. A unique arrangement of bedrooms with strategically placed windows provides a clear view of the sea from every one. The bedrooms and apartments have fresh water showers, extra length beds with innerspring mattresses, ample wardrobe locker space and modern furnishings.

Lounges and clubrooms are separated by partitions of glass which provide satisfactory sound-proofing, yet create the visibility and air of spaciousness which is so all-important to travelers aboard ship.

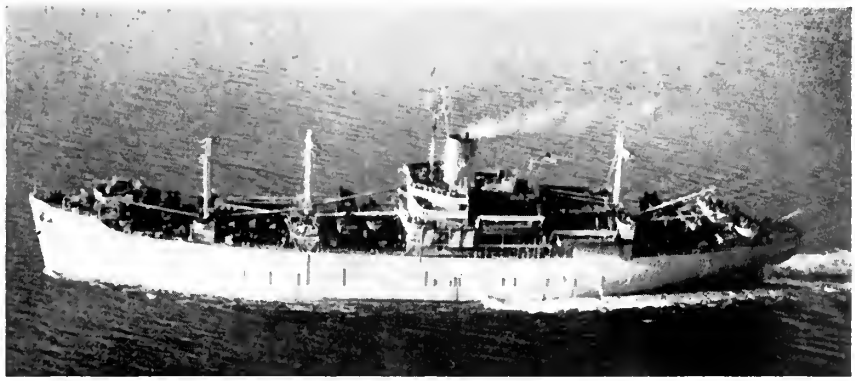
A new method of disposing of smoke and gases high above the deck also is featured on the new ship. The huge teardrop stack, built of aluminum, is false and provides two decks for officers' quarters, emergency generator and radio room, and the real "stack" is a hollow mast which discharges smoke and gases high above the deck, making it cleaner and more comfortable for passengers.

Murals and paintings depicting old New Orleans are combined with the greater use of glass and modern, soft-colored fabrics to give the vessel the pleasing tone of a well-appointed private club.

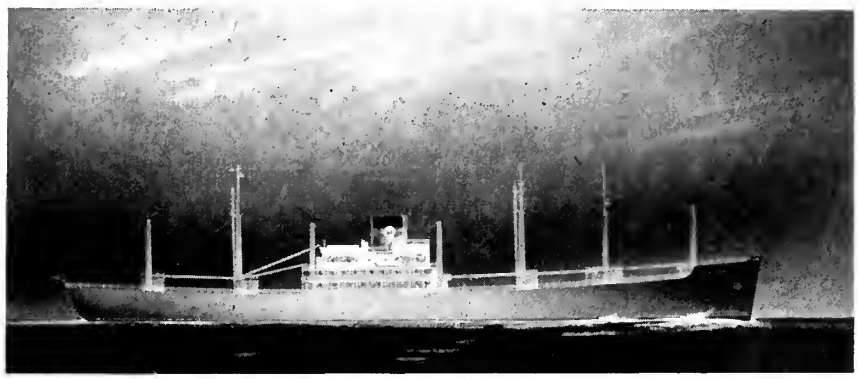
The Del Norte is just as up to date in arrangements for carrying cargo. The vessel has seven cargo holds, and approximately 70,000 cubic feet also is refrigerated and so arranged that it can be used for carrying additional cargo.

All holds except those provided with refrigeration are equipped with "Cargocaire"—a system to control humidity and prevent sweating and consequent damage to cargoes.

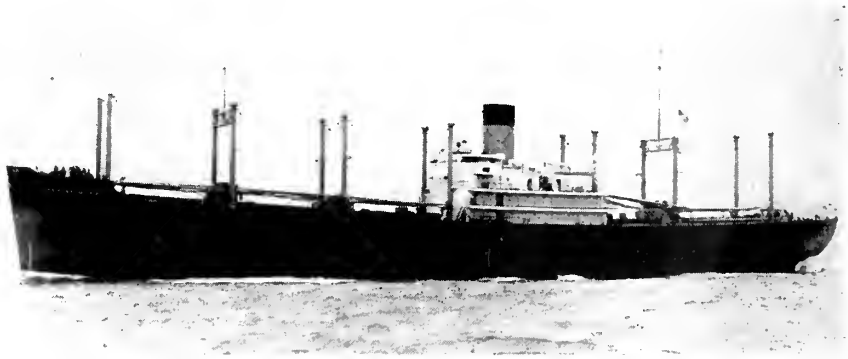
The three ships—the Del Norte, Del Sud and Del Mar, finest ever to make the South American run—will make the trip from New Orleans to Rio de Janeiro in 14 days and to Buenos Aires in 20 days, stopping en route at Santos and Montevideo. Delta Line plans to use the ships on a 47-day luxury cruise from New Orleans to Buenos Aires and return, allowing a week in the Argentine, three days in Rio and sight-seeing trips in Santos and Montevideo.



The USS Griggs, one of the attack transports which the Ingalls Shipbuilding Corporation sent to war from its Pascagoula, Miss., yard, is busy transporting troops from overseas for the Navy. These ships, armed to fight their way close to beachheads to land troops, will be employed as troop transports for five or six months, according to Navy officers, and their ultimate employment has not been decided.



The Ingalls Shipbuilding Corporation is building seven cargo-passenger vessels for the American Scantic Line of Moore-McCormack Lines, Inc., at its big Pascagoula, Miss., yard. This artist's conception shows how the 492-foot, 18,000-ton ships will look when they are completed. The third of these ships was launched recently.



The SS Sea Skimmer, all welded ship of the C3-SA-2 type, recently sailed for New Zealand and Australia under the Matson agency. One of the first peacetime vessels to go into service since the war, the ship, which was built at the Ingalls Shipbuilding Corporation yards in Pascagoula, Miss., was decked out in peacetime paint and featured the new corrugated superstructure which was developed by Ingalls. The Sea Skimmer will carry general cargo and some cargo which requires refrigeration. She also has staterooms for several passengers. She will be used between the West Coast and Down Under on a regular schedule.

ADMIRAL LAND

Vice Admiral Emory S. Land, Administrator, W.S.A.

One of the hardest jobs Admiral Jerry Land ever tackled was that of getting his resignation accepted. On January 4, with most of the major jobs practically "finished" or well in hand, his resignation from the Maritime Commission and the War Shipping Admistration was finally accepted by President Truman.

Typical of Admiral Land was his letter to the President stating that he had "done his bit." His bit was one of the biggest jobs in history. The answer he received was more than a mere formal acceptance and is in itself an eloquent tribute to a great man. It is quoted in full:

THE WHITE HOUSE
WASHINGTON

January 4, 1946

Dear Admiral:

The time has come when it is incumbent upon me to acquiesce with the utmost reluctance in the wish to retire which you have so often expressed during the past few months. It is nevertheless with sincere regret that I accept your resignation as a Commissioner, United States Maritime Commission; Chairman, United States Maritime Commission; and Administrator, War Shipping Administration, effective at the close of business on January 15, 1946, in accordance with the terms of your letter of January second.

I can appreciate that after thirty-nine years in the Navy and nearly nine years on the United States Maritime Commission, all but one as Chairman, you are "war-weary", to quote your own phrase. That the job you undertook was a "headache" none will deny. But your lasting satisfaction will be the realization of your superb accomplishments.

The job which you faced was colossal: the provision of shipping space adequate to support military operations all over the face of the earth. That involved the construction under your leadership of more than fifty million deadweight tons of merchant shipping—an achievement without a parallel in maritime history. There were also collateral problems involving administration, personnel, conversion and a hundred other things, all of which went into the job of creating and maintaining the

(Continued on page 114)

ADMIRAL VICKERY

Vice Admiral Howard L. Vickery.

When Howard L. Vickery left the Bethlehem Shipbuilding Company's Union Plant at San Francisco to become New Construction Superintendent at the Boston Navy Yard he was starting upward toward one of the outstanding accomplishments of history.

Graduating from Annapolis in 1915, Vickery served through World War I on the cruiser Charleston. He took a master's degree in naval architecture at Massachusetts Institute of Technology in 1921 and began the climb. He was loaned to the Haitian Government as Treaty Engineer from 1925 to 1928, and after a year in Washington in the Bureau of Construction and Repair he served for four years as Technical Advisor on Shipping to the Governor General of the Philippines. In 1933-34 he attended the Army Industrial College at Washington and served the next three years as head of the War Plan Section, Design Branch, Navy Department Bureau of Construction and Repair, and drafted the Senate Technical Committee's passenger regulations on Safety of Life at Sea.

As Assistant to the Chairman of the U. S. Maritime Commission from 1937 to 1940, Vickery had supervision over all shipbuilding, design and construction work in connection with the Commission's program to rehabilitate the Merchant Marine.

In September, 1940, appointed by the President as a Member of the United States Maritime Commission through special legislation, necessary because of his status as a commissioned officer on the active list of the United States Navy. As a Member of the Maritime Commission, he continued, in addition to others, the duties in connection with the construction program which he assumed in 1937. This building program, due to war needs, was expanded, and from the year 1939 through 1945, totaled 56,291,678 deadweight tons.

In February, 1942, named Vice Chairman of the United States Mari-

(Continued on page 114)

ADMIRAL LAND

(Continued from page 112)

largest merchant fleet ever built by one nation.

You have indeed done your bit and I am glad to accord to you the thanks of the nation which you have served with such fidelity and efficiency. You are entitled to a rest and after that I want to see you again active in a field which will give scope to your superb talents. With every good wish.

Very sincerely yours,

(Sgd.) HARRY TRUMAN

Vice Admiral Emory S. Land,
War Shipping Administration,
Washington, D. C.

Emory S. Land was appointed to the U. S. Naval Academy in September, 1898. He graduated with honor in 1902, going to the Asiatic Station on the U.S.S. Oregon for two years. At Annapolis he was presented with the Sword of General Excellence in Athletics and was Cadet Commander of the battalion in his graduating year, and received the Bachelor of Science degree.

Commissioned an Ensign, U. S. Navy, he completed a post-graduate course in Naval Architecture at the Massachusetts Institute of Technology, receiving an M. S. degree in 1907.

"Jerry" Land was appointed: Assistant Naval Constructor (1908) with the rank of Lieutenant (Junior Grade); Naval Constructor with the rank of Lieutenant (1912); Lieutenant Commander, Construction Corps, (1916); Commander (1921); Captain (1923); Rear Admiral (1932); and by special Act of Congress Vice Admiral on July 1, 1944.

On the staff of Admiral Sims in London in 1918, he was awarded the Navy Cross with the citation:

"For distinguished service in the line of his profession in connection with the design and construction of submarines and for work in the War Zone."

Admiral Land in October, 1932, was assigned to duty as Chief Constructor of the Navy and Chief of the Bureau of Construction and Repair, and permanent appointment to those positions was made on March 15, 1933. He was placed on the retired list of naval officers, with the rank of Rear Admiral, on his own application April 1, 1937, after 39 years of service. On April 16, 1937, he was appointed a member of the U. S. Maritime Commission for a six-year term, and was assigned immediately to supervise the Maritime Commission's construction program. Admiral Land was named Chairman of the Maritime Commission by the President on February 18, 1938.

Other appointments include: Director of Shipbuilding under the Advisory Commission to the Council of National Defense; Chairman of the Strategic Shipping Board; Administrator, War Shipping Administration; and American Member of the Combined Shipping Adjustment Board.

Decorations include: Spanish Campaign Badge; Victory Medal, World War (Submarines); Navy Cross; Honorary Commander, Military Order British Empire; The Army of Occupation of Germany Medal; Arthur Williams Memorial award; and Gold Medal of Bolivar-San Martin of the Pan American Society.

From 1940-1942 he served as President of the Society of Naval Architects and Marine Engineers.

Contrary to his statement, Admiral Land's job was not finished when he wrote to the President. Just as America will never be finished, so the splendid merchant marine that Admiral Land brought to fruition was not finished with war's end. Its task will be renewed from here on and it will take as wise a head and as strong a hand as his to guide it.

The industry is the better for Admiral Land's service to the country and to it, and is sorry to see him go.

ADMIRAL VICKERY

(Continued from page 113)

time Commission, in which capacity he served until his retirement on December 31, 1945.

In June, 1942, appointed Deputy Administrator, War Shipping Administration, which office he also held until his retirement.

During the war period, Vice Admiral Vickery was a Member of the Production Executive Committee, of the War Production Board; Member, War Manpower Commission; Member, Joint Canadian-United States Defense Board; Chairman, Post-War Planning Committee of the United States Maritime Commission.

He is a member of the Council of the Society of Naval Architects and Marine Engineers; Member, Naval Architecture Committee, as well as Classification Committee, of the American Bureau of Shipping; Member, American Legion; and Chairman of the Board of Trustees of the Cleveland Law School, Cleveland, Ohio.

Decorations: Distinguished Service Medal (Army); Distinguished Service Certificate, American Legion; Morehead Medal for 1945 awarded by the International Acetylene Association; Knight Commander, Military Division of the Order of the British Empire; Victory Medal, World War I; Officer, Grand Dragon of Anam, French Indo-China.

Admiral Vickery is married and has two children: Lt. Comdr. Hugh Blanchard Vickery, USN., and Miss Barbara Willis Vickery.

No man could have had better training for the big job he had to do, and no job could have been more in need of his splendid talents.

We will miss you, Admiral. And we say from the heart to your twelve million fellow Americans in the Armed Services, WELL DONE.

Irene Long

Serving as secretary to an Admiral could be a nice easy way for learning the ways and the lore of the Navy and the sea.

But being secretary to Admiral Howard L. Vickery through all the strenuous years of his Maritime Commission service is a task rather than an opportunity.

Irene Fontella Long, as Admiral Vickery's secretary, helped to keep the ship on its course, and, if such could be possible, made his task lighter and certainly brighter. In doing just that, Miss Long contributed at least her share to the success that Admiral Vickery achieved.

Coast COMMERCIAL CRAFT

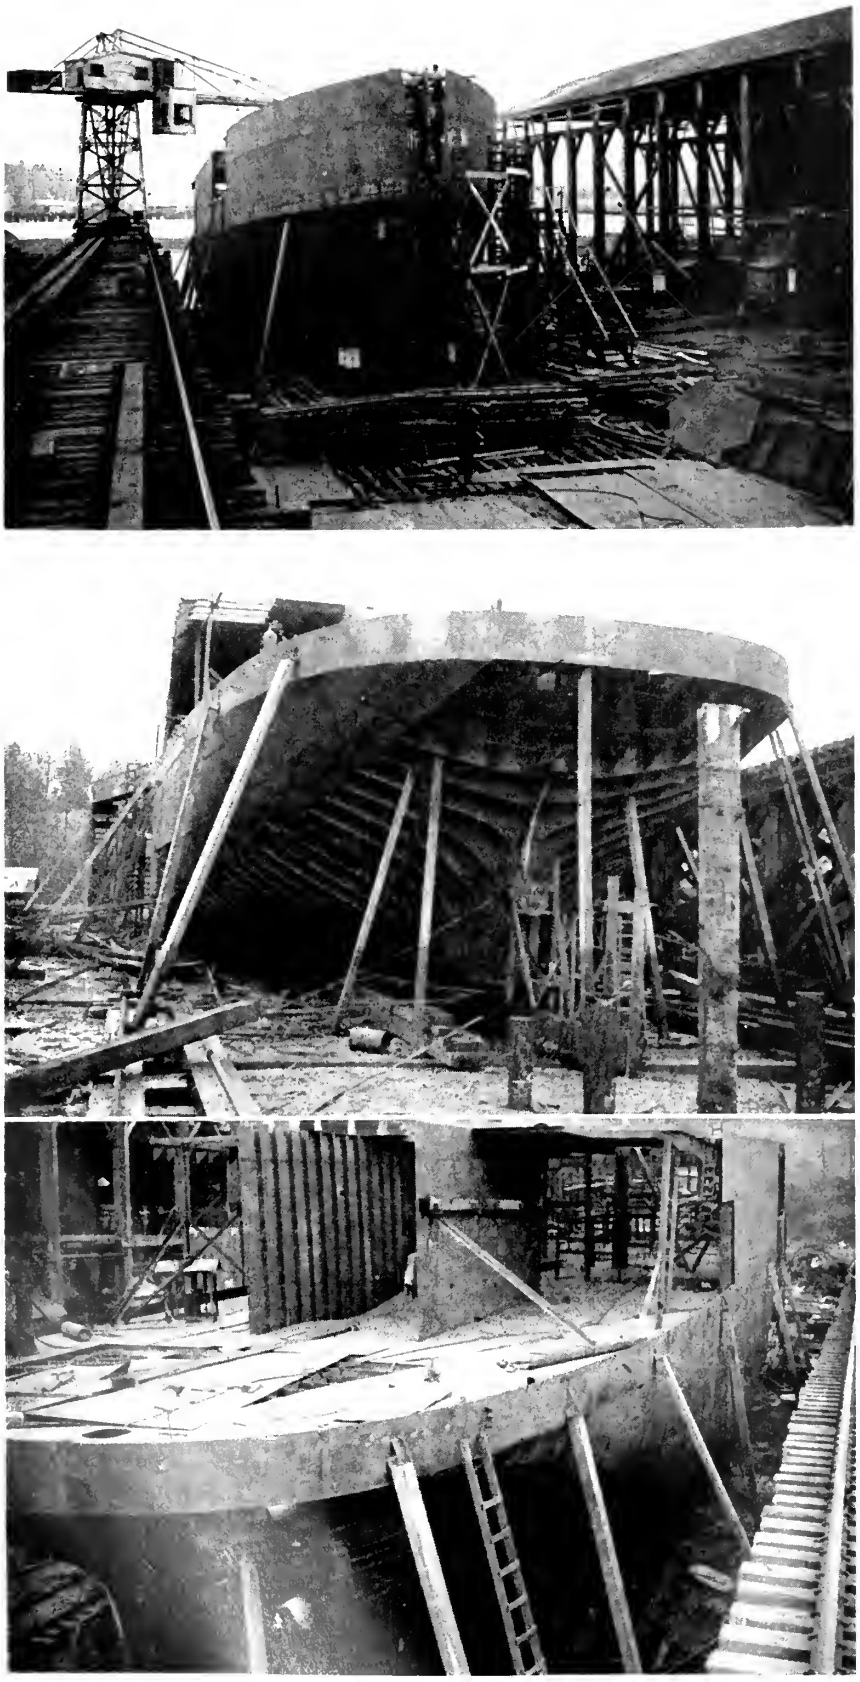
Diesel Freighter for Puget Sound Freight Lines

Construction of the 178-foot welded steel, diesel motor freighter for the Puget Sound Freight Lines is more than half completed at the Reliable Welding Works, Olympia, Washington, and delivery is expected sometime in April. The Puget Sound Freight Lines began preliminary work on the plans for this interesting vessel a year ago after a survey indicated that no vessels had been built during the war or previously that could be satisfactorily remodeled to suit their rapidly expanding trade on the inland waterways of Puget Sound and British Columbia. The modern design of this vessel, which is to be classed by the American Bureau of Shipping for limited coastwise service, has been capably worked out by Carl J. Nordstrom, Seattle Naval Architect.

The new craft has an over-all length of 178′ 4″. She has very pleasing lines, with a moderate beam of 36′ 0″ and a molded depth of 15′ 0″ displacing 1500 tons loaded. When fully laden, she is expected to make better than 11 knots.

The lower hold and main freight

Keel is laid for new Puget Sound diesel freighter. Foreground, left to right: Alfred Solibakke, marine superintendent; Clarence H. Carlander, president; Mrs. F. E. Lovejoy, secretary and treasurer, and widow of founder of the company; Mrs. Howard E. Lovejoy, wife of acting operating manager; George W. Foss, vice president; Carl J. Nordstrom, naval architect; A. W. Lewis, partner, Reliable Welding Works, Olympia, Washington; Don C. Harmon, Olympia district manager. With the exception of Mrs. Howard Lovejoy and Mr. Lewis, all are officers of the Puget Sound Freight Lines.



Three views of the vessel taken on the same date.

deck have over 10 feet of vertical clearance throughout for general cargo. The upper deck is exposed to the weather and may be utilized for deck loads. The carrying capacity is 800 tons of cargo loaded on conventional cargo boards or skips. Deck cargos of pipe, steel, or lumber will be loaded and unloaded by the vessel's own overhead gear. Gasoline-powered lift trucks will load and unload all other cargo. This method of handling and stowing cargo was pioneered by the Puget Sound Freight Lines 20 years ago on pulp movements and was quickly developed for other cargos. Such a revolutionary changeover from the old days of hand trucks has meant specialized equipment throughout and the vessel now being built is the culmination of 20 years of specialized development.

The revolutionizing feature of the design of all of the Puget Sound Freight Lines' vessels is the cargo elevator, which has been incorporated in the design of this new craft, providing access to the cargo decks and compensating for the varying heights of the tide.

The loading operation is accomplished with three-ton-capacity gasoline-powered lift trucks which pick up the loaded lift boards at a point of rest on a pier and carry them over a transfer plank onto the ship's elevator. The elevator is then adjusted to the deck level and the lift truck stows the loaded boards in place. Reversing the process unloads the vessel. The lift trucks easily lift the loads to a height of 8′ 8″, if necessary, so that loads can be set one on top of the other to utilize fully the headroom in the cargo spaces.

The ship is fitted with double bottom tanks forward of the machinery space, providing a large fuel capacity. The peak tanks and the deep ballast tank may be filled with salt water ballast to suit operating conditions.

The engine room is located well aft to provide a large hold for cargo and is confined between watertight bulkheads. Propulsion power will be provided by a 6-cylinder, 16 by 20, 300-rpm, 1200-hp Fairbanks-Morse direct reversible, 2-cycle diesel engine with oil cooled pistons. This engine weighs over 60 tons. It arrived at the shipyard dismantled in two carloads in the middle of January and assembly in the ship started on February 1.

Fairbanks, Morse and Company are providing the fire, bilge and bal-

last pumps, all of the service pumps as well as the two 110 volt DC generators. One generator of 10kw will drive from the main engine flywheel to provide power and lighting when the ship is under way. The other generator, of 25kw, will be driven by the auxiliary power plant, providing power for all of the ship's lights when handling cargo. An Exide storage battery set, consisting of 56 cells, MVA marine assembly, carries the lighting load when the generators are down.

The auxiliary power, furnished by a 4-cylinder, 9 by 10½, 514-rpm, 135-hp Atlas-Imperial diesel engine, will drive a 2-stage 408-cfm Sullivan air compressor having a fresh water cooled intercooler.

Separate fresh water cooling systems are provided for the main and auxiliary diesel engines. Low oil pressure and high temperature alarms are being provided to safeguard both engines.

The elevator winch will be a double reduction air operated unit built by the Washington Iron Works at Seattle. The owners have air operated elevators in five of their vessels, and have found them very successful. The anchor windlass, capstan, and two cargo winches on the upper deck will all be operated by air. The deck winches, in connection with two 8-ton booms stepped on kingposts located just ahead of the navigating bridge, are to be used for handling lumber, pipe, steel, and other cargo not suitable for handling on cargo boards or skips.

The Isaacson Iron Works of Seattle has forged the stern frame and tail shaft. The Nelson Iron Works forged the rudder stock, which is built in three sections. Doran Company of Seattle furnished the solid bronze propeller, which has a diameter of 94 inches and a pitch of 54 inches.

The steering gear, a Sperry No. 2 electric steering engine, is easily changed from power to manual steering in the pilot house. The steering engine will be located inside of the engine casing just under the upper deck.

A radio-telephone for ship-to-ship and ship-to-shore communication, and a radio direction finder, are included in the navigating equipment. The magnetic compass will be installed by the Northwest Instrument Company of Seattle.

The living quarters are to consist of a steel upper deck house, insulated and attractively finished inside with plywood, and a texas. The pilot house and texas will be built of wood. The doors and sash and all joiner work will be of wood. The crew's quarters are large, with two men to a room in the deck department, while the engine room and deck officers and cook each have quarters of their own. Basins and lockers are provided in all rooms. There are five showers and five heads. A day room is provided on the starboard side of the upper deck house for the crew's recreation. Heating will be by hot-water system with oil burner in the engine room and convector radiators in each heated space.

Setting shell around starboard bow above main deck.

The galley and messroom, located in the after end of the upper deck house, will be light and cheerful. Equipment in the galley includes a Lange oil-burning galley range, a large household type refrigerator and stainless steel sinks and drainboards. A large storeroom adjacent to the galley includes a walk-in refrigerator.

Cold drinking water may be had at any time at a drinking fountain that has coils inside the walk-in refrigerator.

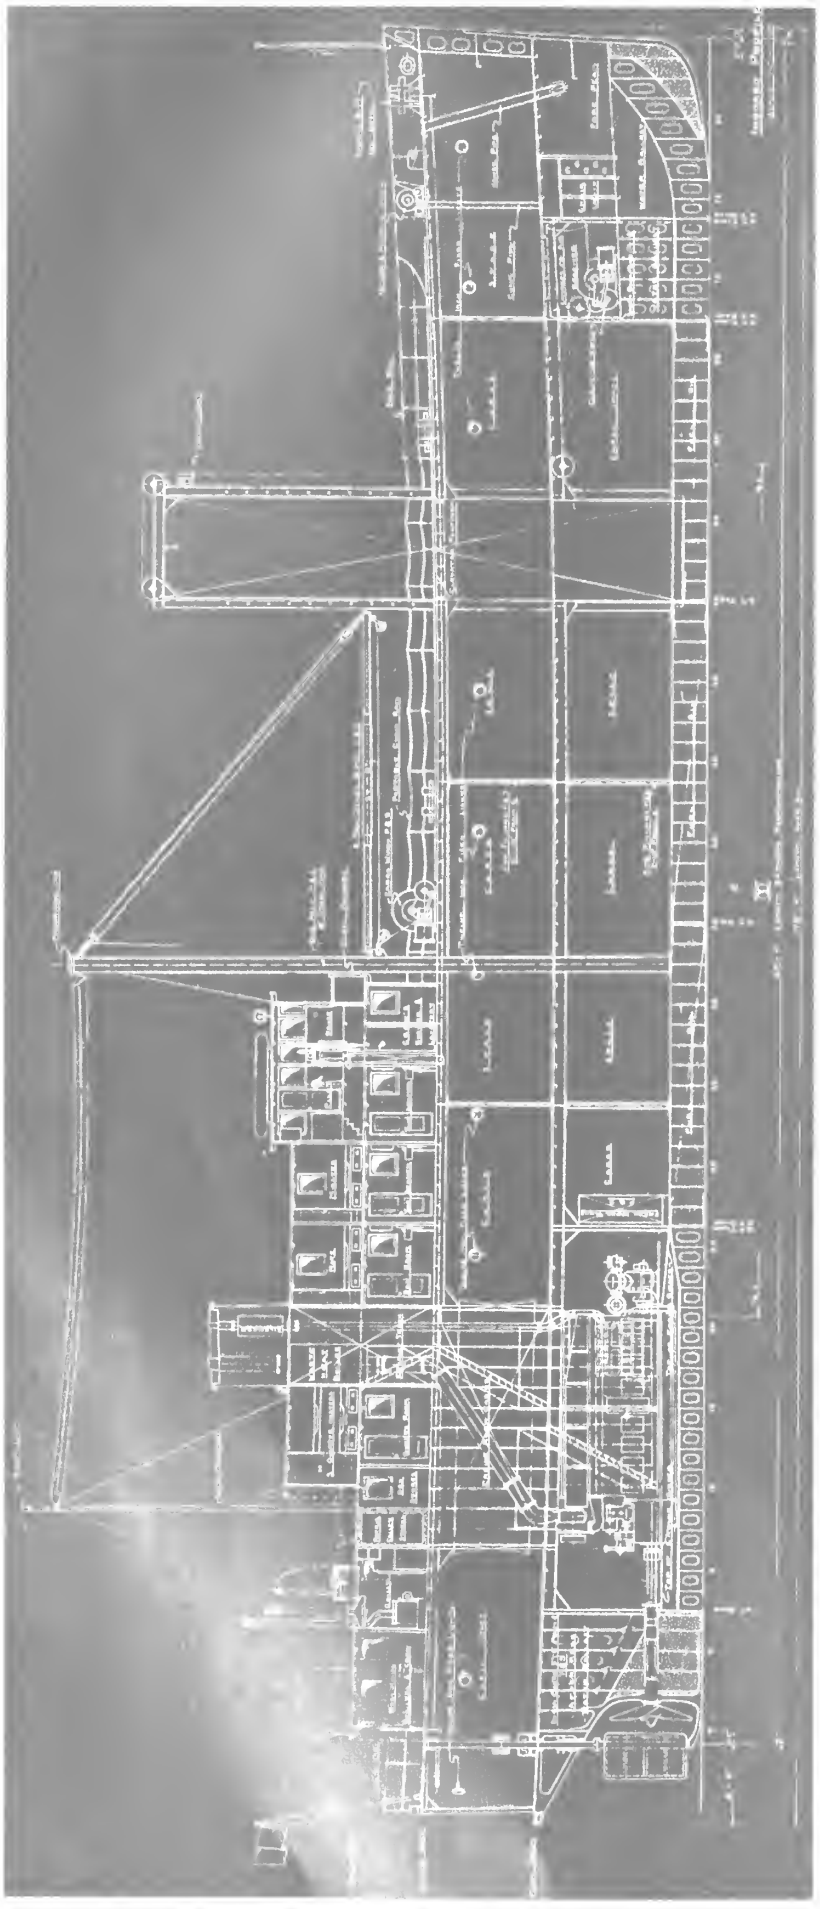
Carl J. Nordstrom designed this vessel upon returning to civilian life after more than four years as a Navy commander. He had charge of all design and construction in connection with the remodeling of many former well-known transpacific liners into military transports and later with the overhaul and repair of naval vessels in the Seattle area. He has opened offices in the 905 Second Avenue Building, Seattle.

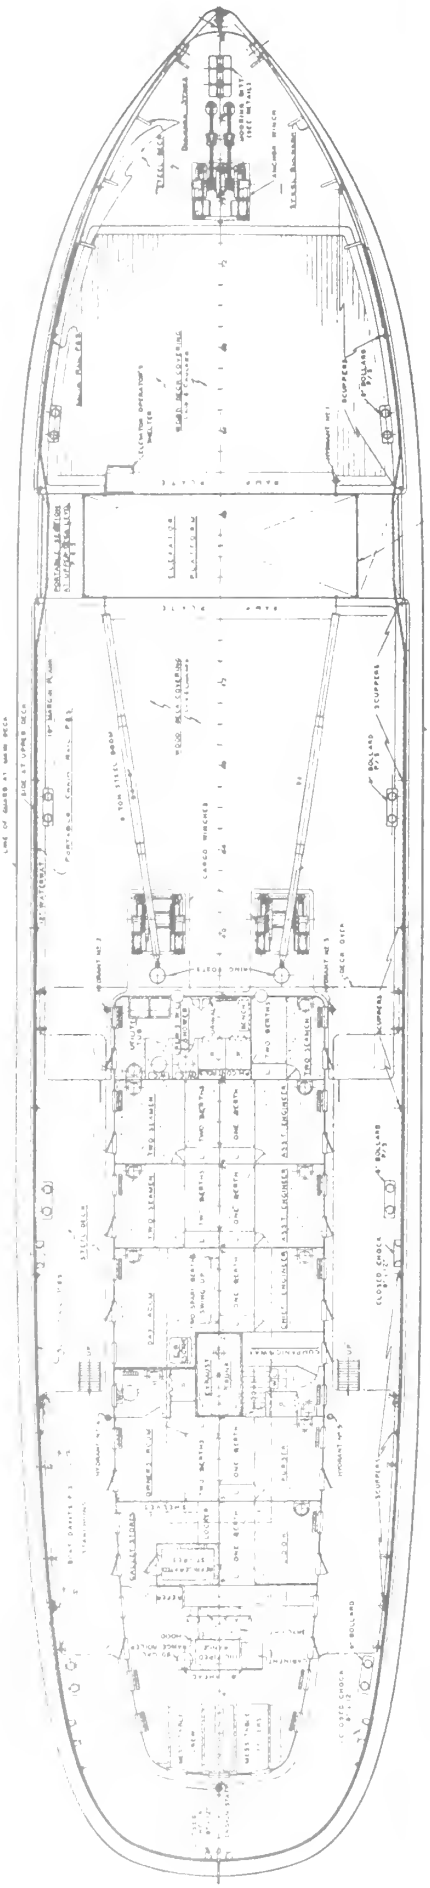
The Reliable Welding Works have been building commercial and Government vessels for the past ten years. During the war they built 22 tugs for the Army and a number of barges and commercial boats, including a 130-foot tuna hull. Their yard is specialized in the building of all welded steel vessels up to 200 feet in length. A. W. Lewis, owner, began his shipbuilding career as an apprentice shipbuilder in the Bremerton Navy Yard in 1915.

The Puget Sound Freight Lines was established in 1919 by Captain F. E. Lovejoy, and is today one of the largest operators in the inland water freight transportation business on the Coast, owning the following fleet of vessels: Warrior, 156 feet long, twin 200-hp Atlas diesels; Indian, 165 feet, 500-hp Atlas diesel; Seatac, 120 feet, 300-hp Fairbanks-Morse diesel; Skookum Chief, 125 feet, twin 180-hp Washington diesels; Belana, 105 feet, 240-hp Fairbanks-Morse diesel; F. H. Marvin, 125 feet, two 100-hp Fairbanks-Morse "CO" diesels.

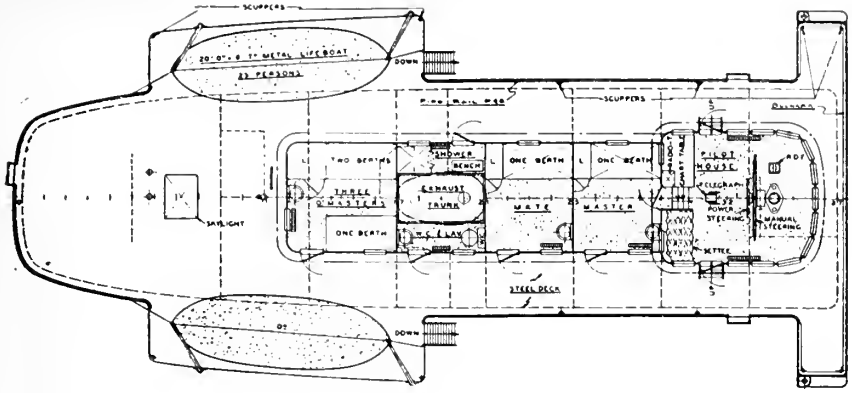
The company's business has steadily grown and expanded from the first, due to its methods of handling freight and to complete transportation service given its patrons in the Puget Sound, British Columbia and Grays Harbor area.

In addition to its fleet of vessels, the company owns its own docks in Bellingham and Olympia, nine 7-ton trucks, and five 16-ton tractors and semi-trailers, which are used in carrying freight between Aberdeen and Olympia as a feeder service to freight





Outboard profile and arrangement plan of Puget Sound freighter.



vessels plying between Olympia, Seattle and Tacoma, and other Sound ports, and for pick-up and delivery of freight in Bellingham, Olympia and Shelton. Terminal equipment includes 46 cargo power lift trucks, four automatic transporters, and considerable cargo handling equipment, including 4800 wooden cargo skips and 4000 cargo lift boards.

Present officers of the company are: Clarence H. Carlander, president; George W. Foss, vice president; and Edith R. Lovejoy, secretary and treasurer. Mr. Carlander, the present head of the company, has been associated with the organization ever since it was first founded, and became president of it when Captain Lovejoy died on October 4, 1940. Howard Lovejoy, the latter's son, is resident construction supervisor at Olympia while the new freighter is being built.

Other operating officials are as follows: David B. Fairley, assistant secretary-treasurer and auditor; Alfred Solibakke, marine superintendent; J. Knox Woodruff, operating manager; George B. Cooper, purchasing and claim agent; Alfred E. Bourke, Seattle agent and dock manager.

James Wright is general freight agent; Louis Coupez, chief, billing department; Albert W. Brazas, Bellingham district manager; Don C. Harmon, Olympia district manager; and Fred Erickson, Aberdeen district manager.

Hull Corrosion Licked

On drydocking the Case-American Construction Company electric dredge San Diego on July 27, 1945, a graphic picture was revealed of the protective properties of a plastic coating which it is said may revolutionize the conventional methods of protecting hulls against the corrosive action of sea water. It was found that a large test area on the bottom and side of the dredge which had been coated in June, 1941, with an American Pipe & Construction Co. product, Amercoat No. 23, appeared to be in practically the same condition as when first applied four years before, while the remainder of the hull, which had been coated twice in the four-year interval with conventional means, presented a completely etched, corroded surface, pitted in some areas to a depth of 1/16th of an inch.

Because of the extremely successful record of the Amercoated test section of the hull, the entire hull of the San Diego was Amercoated in July, 1945, before the dredge was placed back in service.

Applications to date of the Amercoat coating have not only proved its practicability in the marine field, but have excited the interest of engineers everywhere where corrision is a problem.

Applying plastic coating to electric dredge San Diego.

Grace Line Acquires Two Tugs from Maritime Commission

With the arrival of the Grace II and the Grace III in New York on January 10 from Jacksonville, Florida, Grace Line put into operation two tugs recently purchased from the U. S. Maritime Commission. Both tugs will be used in conjunction with the Grace I for lighterage work and ship docking at Grace Line's Hudson River terminals.

The Grace II was built by Ira S. Bushey & Son and the Grace III by Consolidated Shipbuilding Corp., both of Jacksonville, Florida.

Each tug has a length of 85 feet, a beam of 24 feet, and a draft of 9 feet 8 inches. Propulsion is by 700-horsepower General Motors diesel engines.

Atop the wheel house of S.S. Catalina, troop-carrying steamer of the San Francisco Port of Embarkation's Harbor Fleet, Major General Homer M. Groninger, Port Commander, inspects the ship's new radar installation. He is accompanied by Captain Howard J. King, master of the ship, and H. V. Cashdollar, radar engineer of the Port of Embarkation. Bruce Lawrence, ninth service command radar engineer now working at the Port, and Joseph F. Poplosky, radar expert from Raytheon Manufacturing Company, makers of the instruments, are shown colibrating the antenna at top of picture. The antenna is protected from rain and the winds which would retard its circular movement by the large plastic haad, the upper part af which lies on the deck (center). The transmitter-receiver box (under Capt. King's hand) automatically switches on and off 400 times a second. Radio impulses travel up the inside skin of the wave guide (the square vertical pipe) and bombard the antenna; travel thence until they hit a target and are reflected back to the antenna and back down the wave guide to the receiver. 60,000 watts af pawer are used. Instrument is Raytheon Manufacturing Company's SO-8 model. *(U. S. Army Signal Corps Photo.)*

Radar on Harbor Craft

Disclosure that the troop-loaded ferry Hayward, which ran aground in the tricky river channels of upper San Francisco Bay in a recent pea soup fog, was located by the Army's newest floating radar installation, lifted the lid on San Francisco Port of Embarkation's plans to battle the area tule fog.

The Hayward was picked up on the radar "scope" of the Army's steamer Catalina, first harbor vessel to get the special electronic equipment, as the latter ship neared Camp Stoneman with her just-returned veterans.

The run to Stoneman, first leg on the final homeward trip after Pacific warriors are debarked at San Francisco Port of Embarkation, is often more difficult than deep sea operation, due to narrow channels and frequent fogs. Without radar, these channels are run only by visual reference to buoys and markers which trace the winding paths.

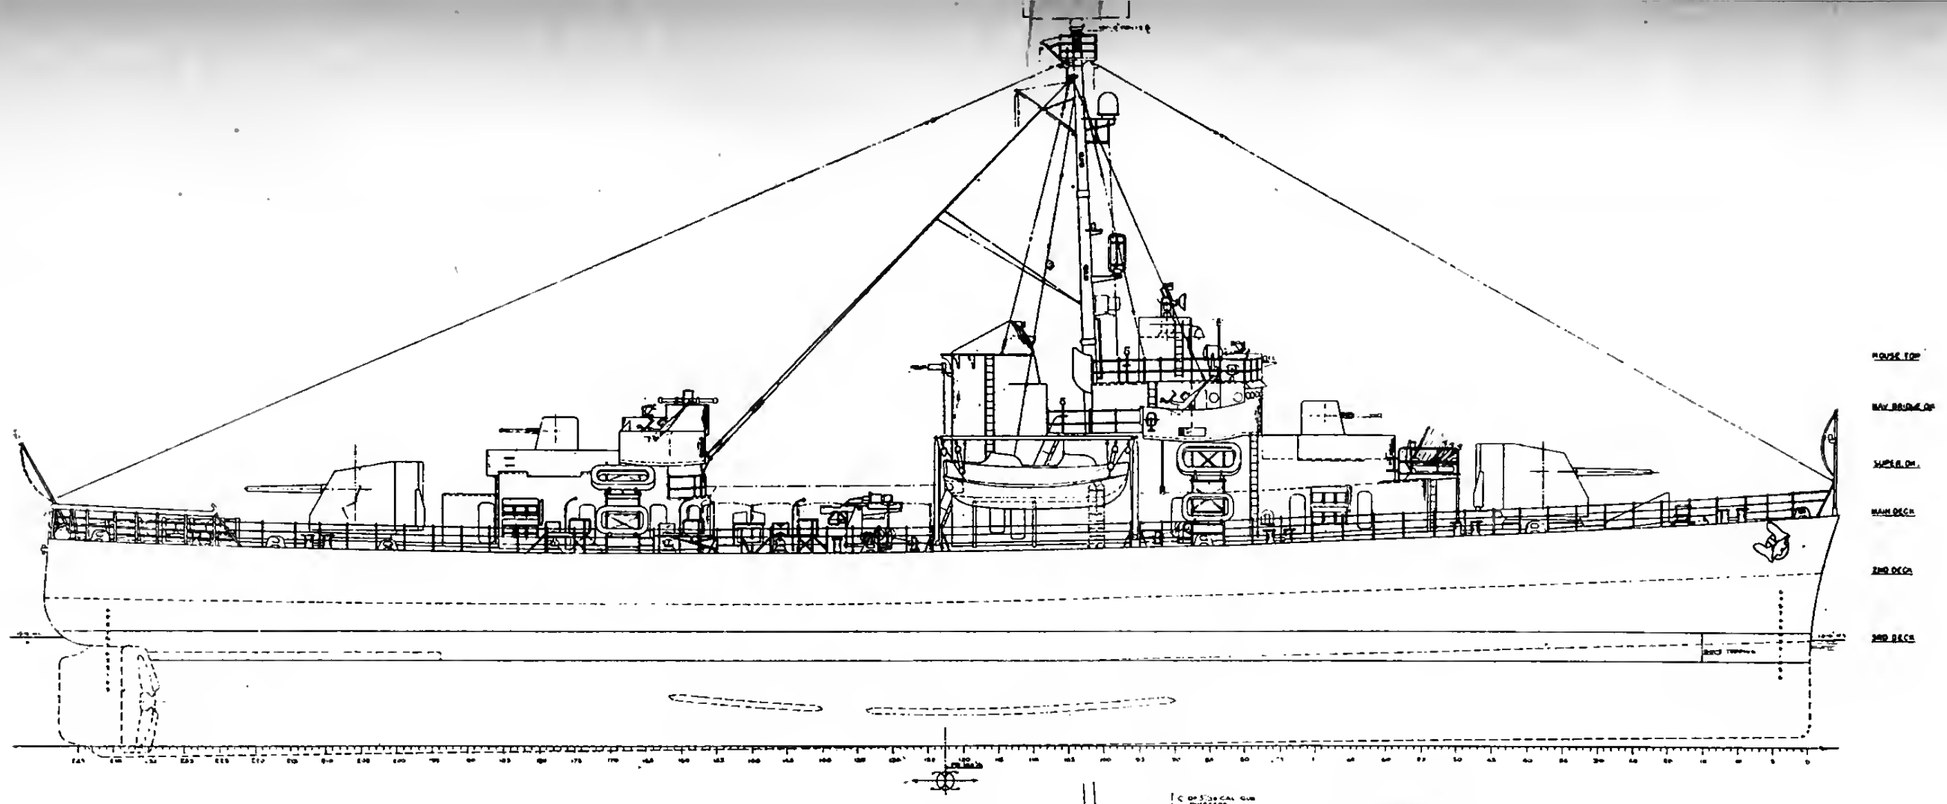
"The motive behind all Port operations is to speed the return home of the veterans coming in from the Pacific," Major General Homer M. Groninger said in setting the keynote of the radar operations. "With the special radar which we have installed on Army troop ships and which we are now placing on the harborcraft, the ships and ferries can make maximum speed in all weather and can enter the Golden Gate and narrower channels regardless of the degree of visability."

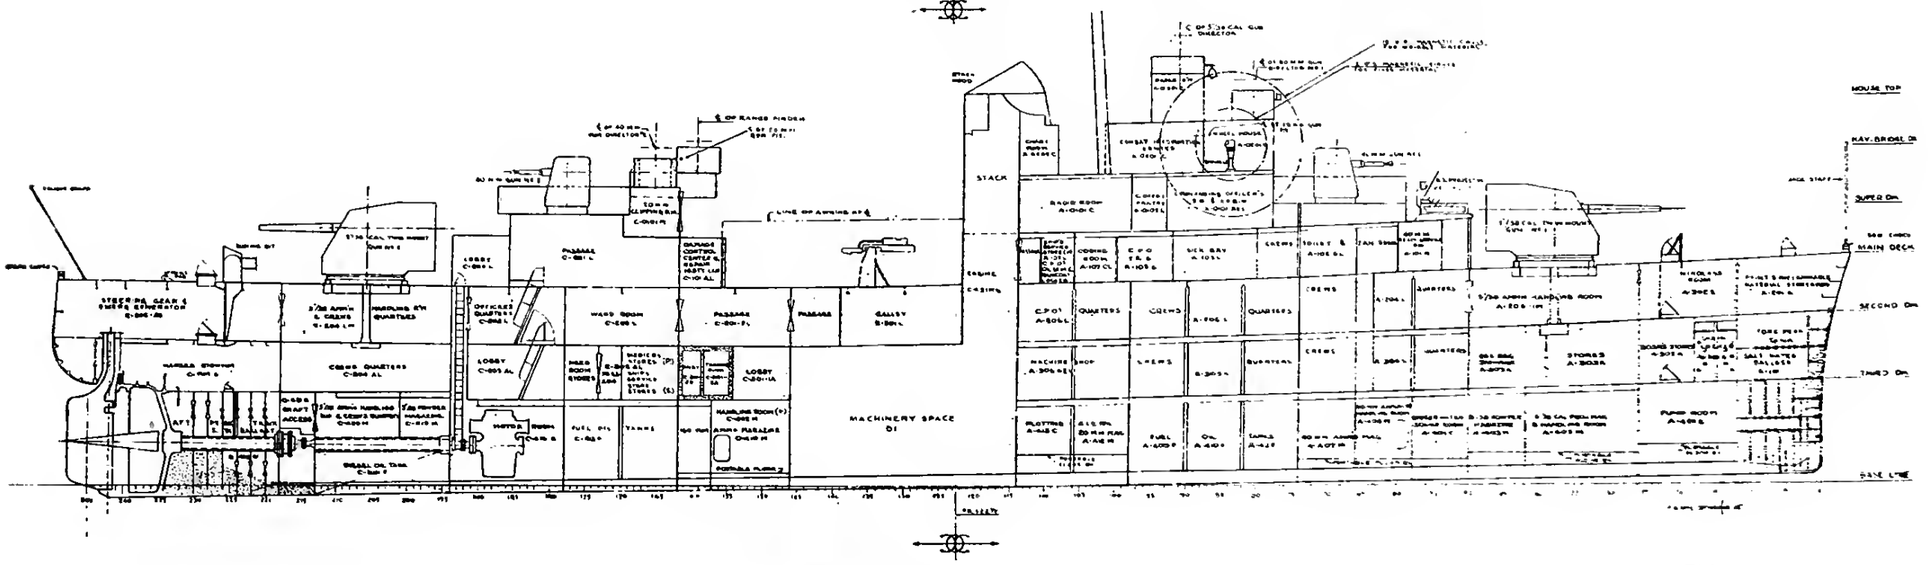
The trip on which the temporarily grounded Hayward was located was the first regular trip on which radar was used for river navigation. When the War Department initiated installation of radar equipment on Army deep sea ships some months ago, port signal officers secured an obsolete set for experimental river use on the Catalina, peacetime link between Los Angeles and Catalina Island off the Southern California coast. The main problem was to so adjust the instrument as to enable detection of close-in objects. Radio waves which strike targets within three hundred yards are reflected back to the ship too quickly to be pictured on the radar scope, and as the distance between many turn-locating channel markers is often but a scant hundred yards, any mechanism used had to have a super-fine adjustment.

When experiment with the obsolete equipment aboard the Catalina proved the feasability of using radar for channel work, a special type of the most modern equipment was installed. By fine adjustment of the instrument after each use, Port signal officers declared that results are far better than are normally expected. It is operated by a soldier technician, but Captain Howard J. King, master of the vessel, interprets the outlines and "pips" in the radar scope, when handling his vessel in the fog and at night. King has, as a result of his use of radar in San Francisco Bay, become an enthusiast who "wouldn't be without it."

While Captain King had his initial instruction aboard the vessel, Army operators who are put aboard transports as they are radar-equipped by San Francisco Port of Embarkation, are graduates of the Port's Special Electronics School. Set up under General Groninger's direction by Captain Frank L. Treadway, head of the Port's radar installation and one of the early graduates of the Army Radar School in 1942, the post-graduate electronics course features two complete radar systems of the type which soldier-operators will use and maintain aboard ship. The three weeks course, conducted at Fort Mason by Lt. Stanley Owens, draws its students from men who have previously completed basic radar instruction at the Fort Monmouth, N. J., Signal Corps School.

Installation of radar equipment takes eight to ten days on transports and four to five on harbor craft. The installations are supervised by H. V.



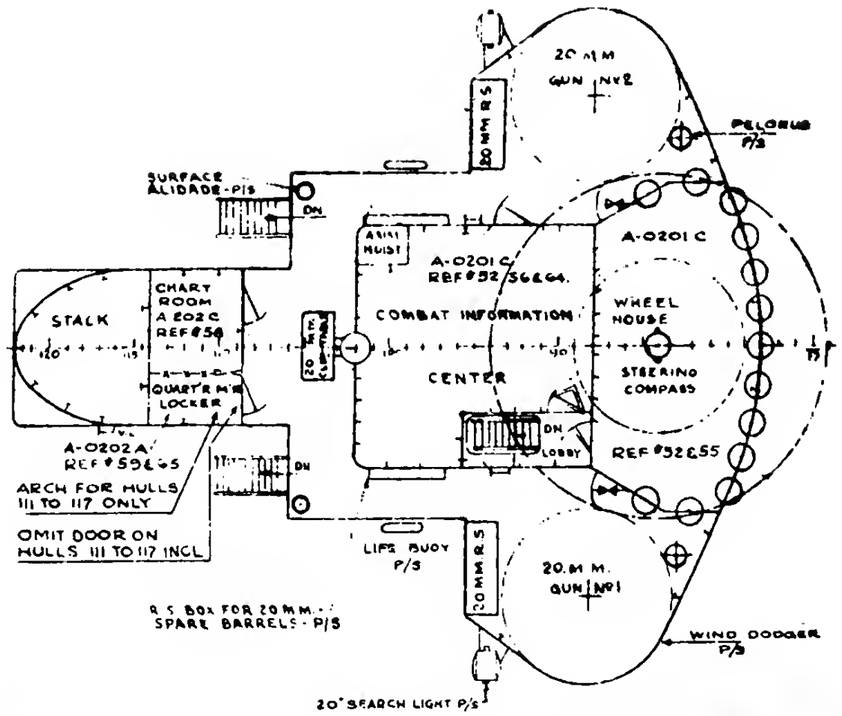


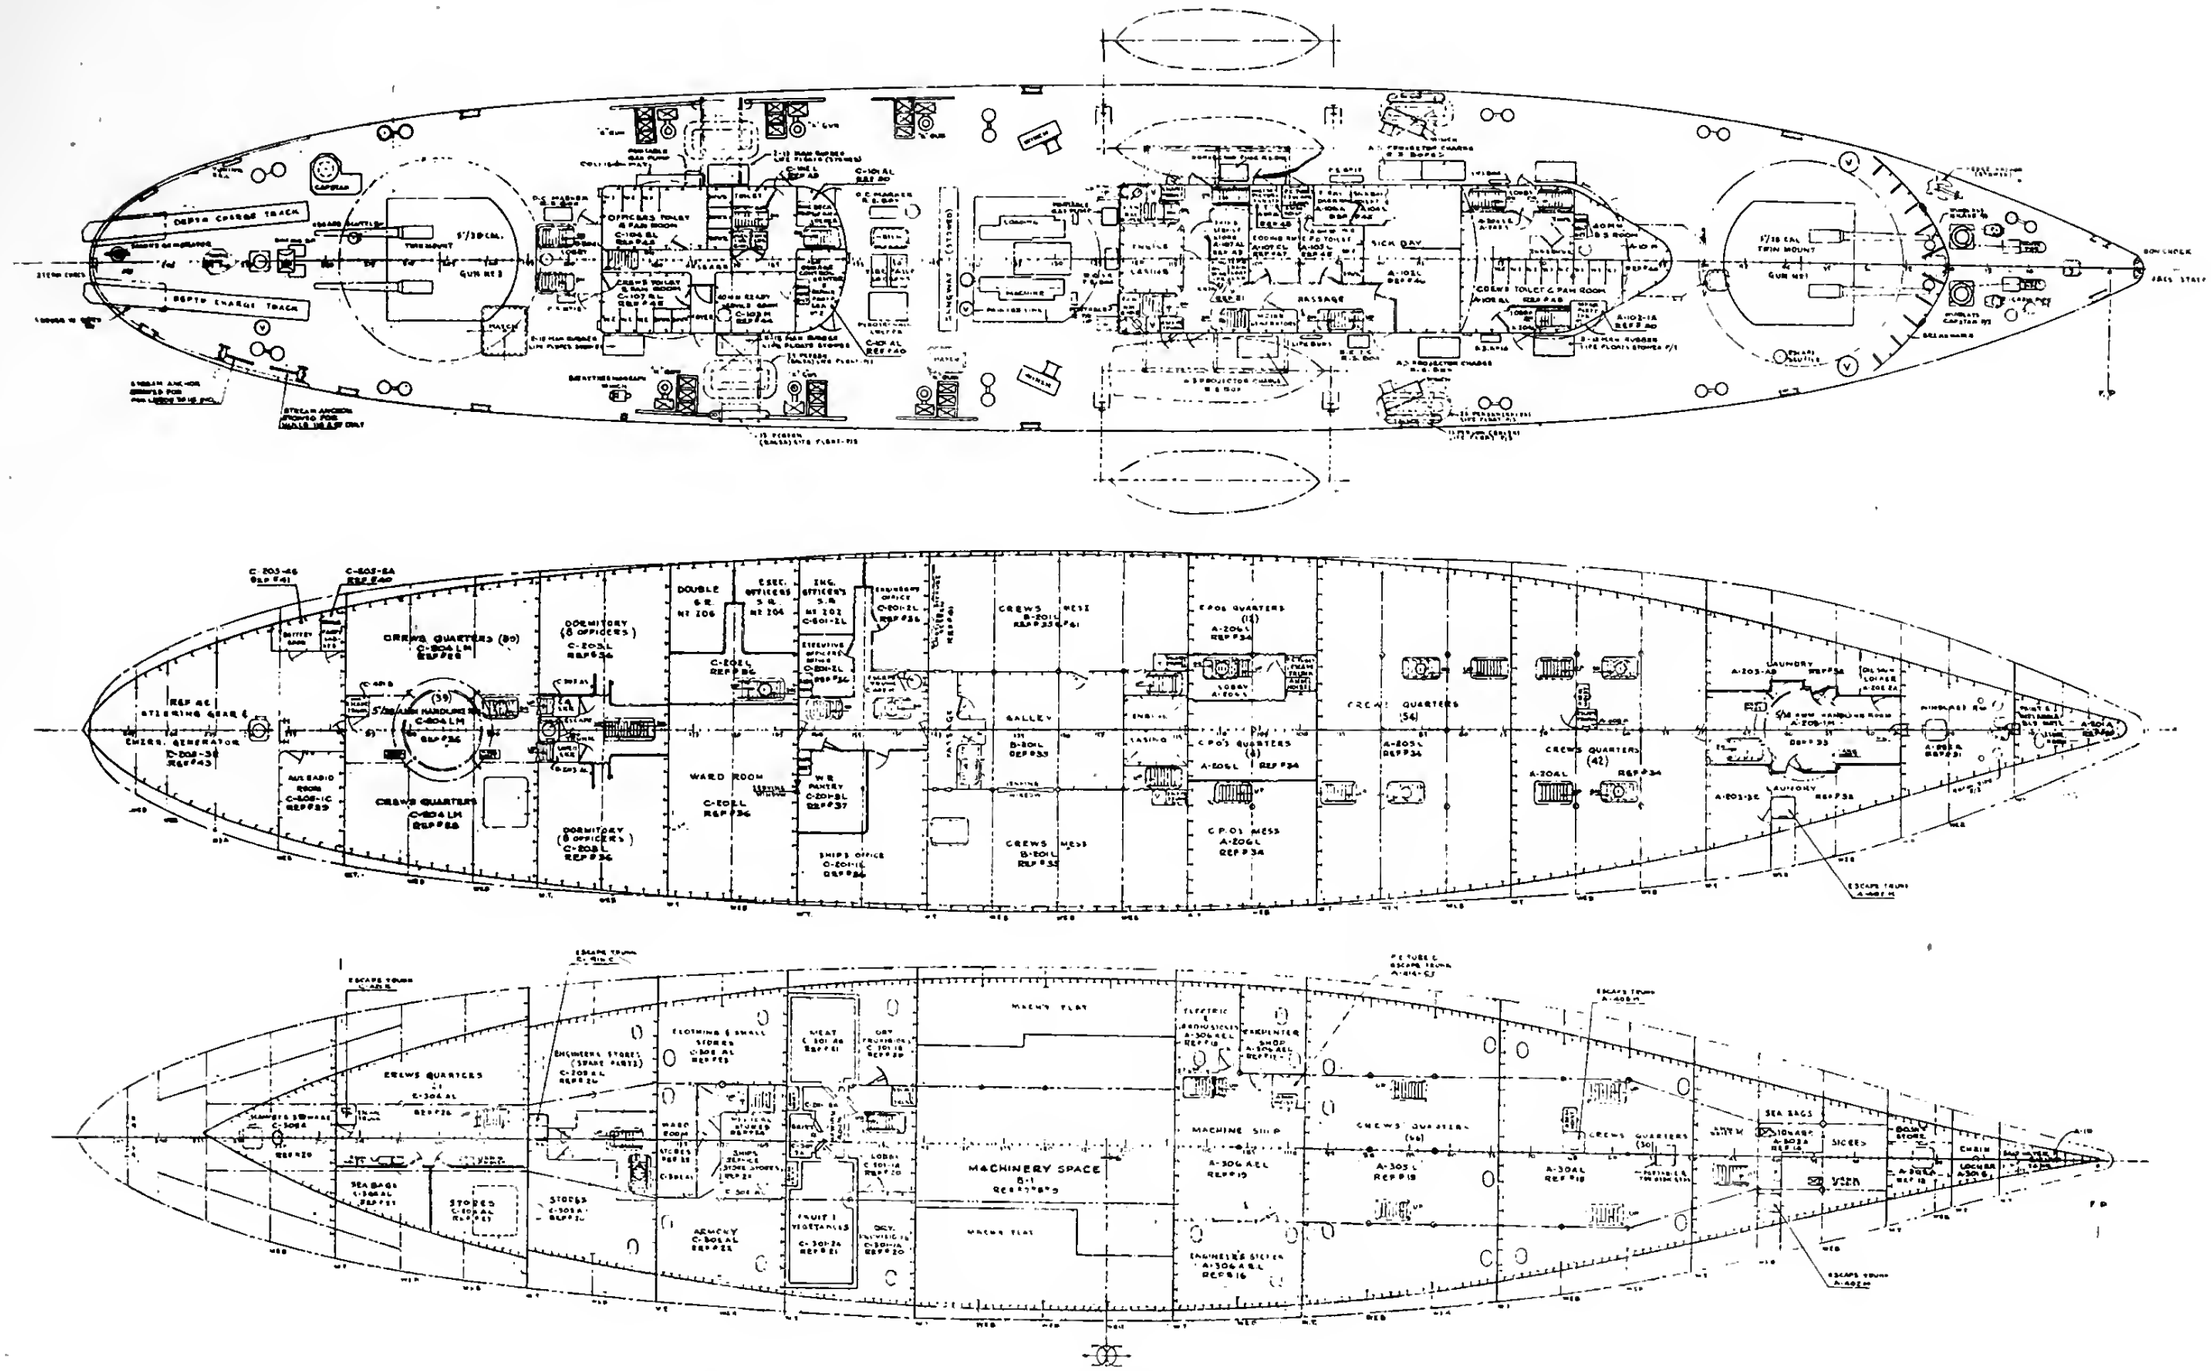
COAST GUARD CUTTERS

Last month we published an article entitled "Turbine-Electric Coast Guard Cutters," by J. A. Wasmund of Westinghouse, and announced that arrangement plans would follow. In the plans herewith and on opposite side of this insert the wartime arrangement is shown. However, the armament will be reduced considerably for the peacetime activities of the Coast Guard. There are 13 cutters of this class, the general characteristics of which are as follows:

Length Over All	254 feet
Beam (Molded)	43 feet
Draft (Design)	15 feet
Shaft Horsepower	4000

The cutters are propelled by a single screw. The power plant is turbo-electric, synchronous AC. Steam is obtained from two Foster Wheeler two-drum express oil-fired boilers, fitted with superheaters and economizers. The hull has special form and is strengthened for working in ice. Particular attention has been given to crew accommodations, for comfort and convenience, crew's quarters, as well as officers' quarters, being equipped with air-conditioning. For wartime purposes, armament and control were very complete. It is believed that these ships were the heaviest armed vessels for their length afloat. When stripped down for peacetime operation, the completeness of equipment and outfit will leave nothing to be desired.





Arrangement Plans of Turbine-Electric Coast Guard Cutters

(Continued from other side)

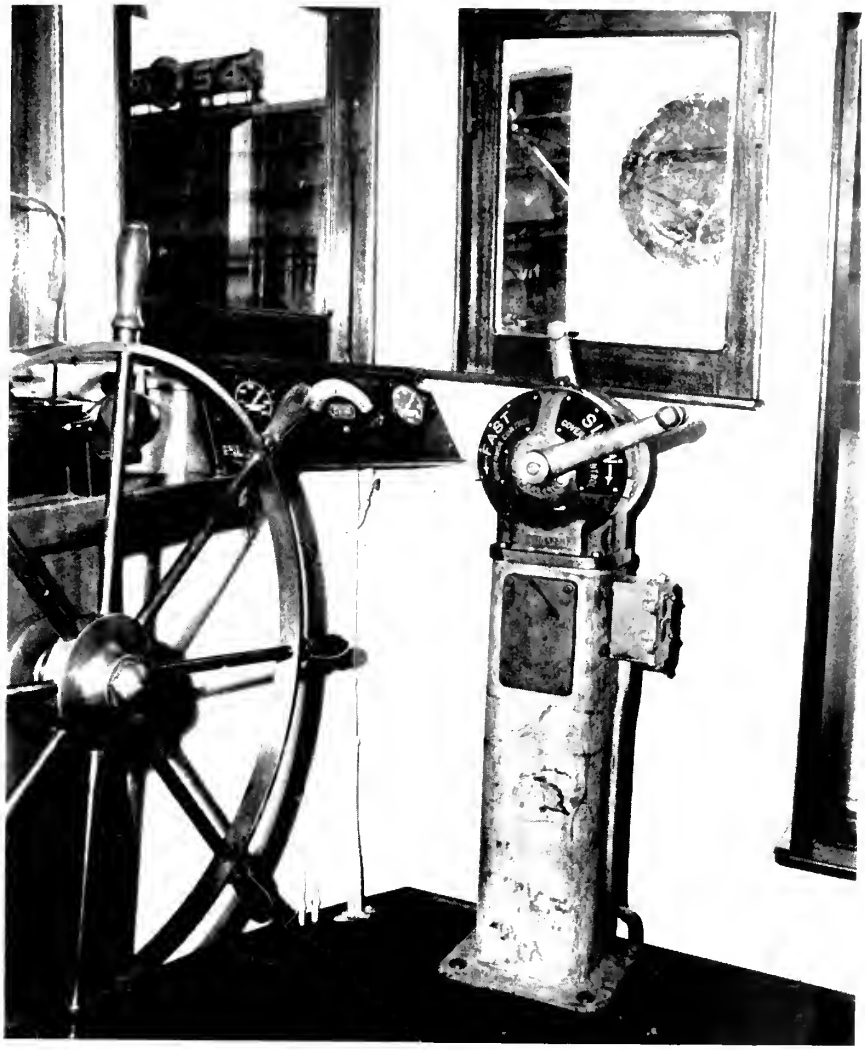
Cashdollar, war-time radar instructor for the Navy and request the services of no fewer than eight trained men. Much of the local installation for the larger troop ships is done under Army contract and supervision by bay area shipyards.

Shrimp Boat Built at Tacoma For Gulf Fishing

A very interesting shrimp fishing craft, built by the J. M. Martinac Shipbuilding Company in Tacoma, Washington, for Major J. H. Pullen of Houma, Louisiana, recently left the Pacific Coast and is now fishing in Gulf waters.

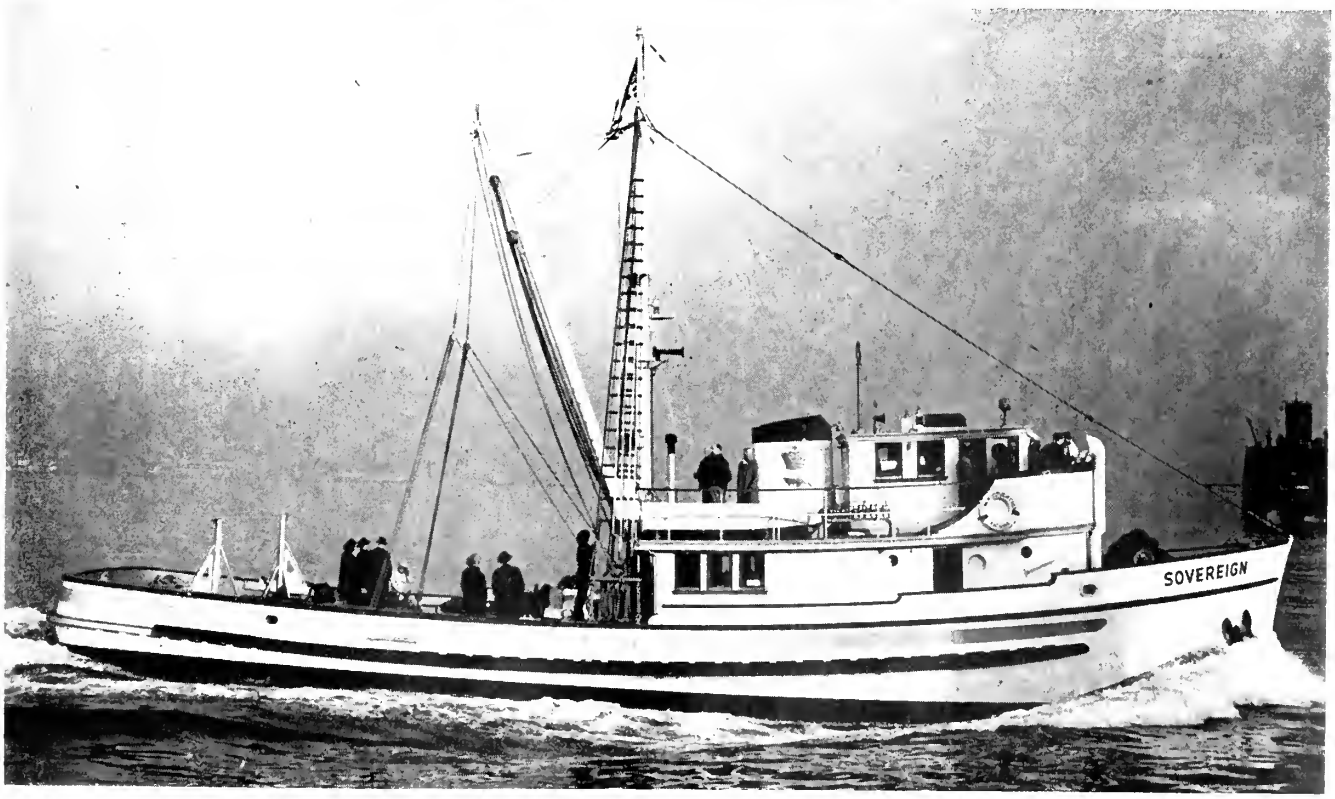
This vessel, named the Sovereign, is the first of a proposed shrimp fishing fleet which Major Pullen and his partner, Albert E. Fletcher, intend to build and operate in this important activity in the Gulf. It was designed by the shipbuilders to meet the particular requirements of the co-owners at a cost of approximately $130,000.

She is a smart looking craft of wood construction, with a raised foc'sle and a trim sheer line, a length of 82 feet and a beam of 26 feet. Her main propulsion unit is an Enterprise



Right: Corner of pilot house, showing steering wheel and Enterprise machinery controls and gage panel.

Below: New shrimp fishing boat for Gulf of Mexico waters on trial run.



Enterprise D.M.G.-6 400-hp main propulsion unit on the shrimp boat Sovereign.

D.M.G.—6 diesel engine of 400 hp at 400 rpm, which drives a main shaft with a Coolidge propeller of 66 inches diameter and 39 inches pitch. The cruising speed is 11 knots and the vessel is fitted with refrigerated holds of a capacity of 150,000 pounds of shrimps.

Accommodations for a crew of ten men and the two owners are provided in a deckhouse running from midships forward on the weather deck.

It seems noteworthy that the owners should come to Pacific Coast builders for a vessel which will operate in Gulf waters.

A Modern River Towboat

The new 112-foot towboat Codrington underwent final trials on January 10 at Nashville, Tenn. Named for George W. Codrington, vice president of General Motors, she was built by the Nashville Bridge Company at Nashville, and will be the largest towboat of a fleet of four boats operated by the Canal Barge Company of New Orleans on the Mississippi and Ohio Rivers hauling fuel oil.

Powered by a 16-cylinder 2 cycle General Motors diesel engine with a rating of 1235 bhp at 700 rpm, she is driven by direct connection Air-Flex clutch reverse reduction gear unit with the propeller shaft turning an 82" three-blade propeller at 304 rpm. The auxiliary equipment consists of two General Motors generator sets, each consisting of a 3 cylinder 2 cycle General Motors diesel engine and a 20-kw marine type generator.

The hull and superstructure are all welded steel construction. The towboat is equipped with pilot house control. This feature insures rapid maneuvering because all control of the engines is done by simply moving the speed controller lever—no vocal or manual order need go to the engine room. The rudders are operated by a pneumatic steering engine also controlled from the pilot house. In addition a special type Nabrico seminozzle has been installed to increase the thrust of the vessel.

R. R. Thorpe is captain and William Andrew is chief engineer.

"Plasticraft" Boats

"Always above water," a phrase used by Winner Mfg. Co., Inc., of Trenton, New Jersey, in referring to their products, is especially appropriate for their new unsinkable plastic boat.

The hull is a "sandwich" composed of two outer layers of lightweight duck, a low density core of sisal fiber matting and an inner layer of heavy duck. This combination is impregnated with a compound consisting of Bakelite resin with special chemicals and a neutralizing agent which helps the canvas to retain its original resiliency and tensile strength. With the "life" of the material unimpaired, there is no excessive rigidity and resultant brittleness. Instead, this type of construction makes the Plasticraft rebound rather than smash or dent when contacting a foreign object in the water.

The impregnated assembly is then laid up on a form to which a pressure of less than 50 lbs. per square inch is applied. After a short cure, a lightweight shell (only 73 lbs. for the 10 ft. dinghy) is stripped from the mold. Being seamless, it is watertight, and seasonal calking or pitching is eliminated at the outset.

The gunwhales, seat raisers, keel and keelson are bonded to the hull with phenolic-resorcinol cold-setting waterproof glue. With the addition of woodwork, seats and trim, the finished 10 ft. dinghy weighs but 142 lbs., making it possible for two persons to lift it with ease.

Being self-buoyant, the craft will not sink under any conditions. This same characteristic provides unusual freeboard with minimum draft . . . on slightly more than a heavy dew, as the Winner engineers so deftly put it.

The Winner line of Plasticraft includes dinghies for sailing, rowing, and outboards. Distribution will be made through dealers at a nominal figure in line with other boats of similar sizes.

Swedish Shipbuilding

By A. J. Dickie

DURING JANUARY the Johnson Line motorship Bio-Bio visited Pacific Coast ports on her maiden voyage. She had a fairly full load of Swedish paper products, Central American coffee and hardwoods, and refrigerated cargo. Since she is an excellent example of the post-war product of Swedish shipyards, and since Sweden is now the third shipbuilder in the world, we are compiling this article so that our readers may understand the competition that is facing American shipbuilders.

The Norwegian shipowners are probably the largest single block of customers for the Swedish yards. As of December 1, 1945, Norwegian orders in Swedish shipyards amounted to about 400 vessels, practically all of which are to be motorships. Not all of these vessels will be used in the Norwegian merchant marine. Many of them will be sold on delivery, and undoubtedly quite a number will be sold on the ways to the shipowners of other nations. Norse ship owners and ship brokers are always a little ahead in sizing up future trends in the ship business.

Every shipway in Sweden is occupied and has a nice backlog of orders. Most Swedish yards are prepared to build engines as well as hulls.

Bio-Bio was built by Kokums Malmo Sweden. Her steel hull is largely welded. All frames and deck beams are serrated so that the welding of these heavier members to the deck and shell plating is now continuous. This avoids locked-up strains and considerably lightens the framework of the ship without sacrificing stiffness. The welding was a very neat job. In all the trunked hatches the brackets for the strong backs were welded to the hatch combing and were further supported by a round steel bar with both ends spherical, which was welded at its upper end to the outer corner of the bracket and ran down and over to the bulkhead on an easy curve to a couple of spot weldings. This not only supported the bracket but acted as a guard to prevent the hook or a load catching on the bracket corner.

Bio-Bio is propelled by two Kokums M-A-N single acting diesel engines, each connected driectly to one of the twin screws and each delivering 3,750 shp. She carries also three auxiliary generating sets with Kockums M-A-N engines and Asea generators. Practically all of the auxiliary machinery is electrically driven by Asea Motors. An interesting feature of the engine room is the refrigeration corner where the refrigeration engineer can control the temperature of every refrigerating compartment on the ship. It is claimed that this control is so adjusted that any compartment can be maintained at a certain predetermined temperature, plus or minus one-half degree Fahrenheit, all the way from Stockholm to San Francisco, through the Panama Canal. Bio-Bio is equipped with a waste heat boiler that furnishes steam for heating and cooking and for warming coils in the fuel oil tanks. Lubricating oil and fuel oil is centrifuged in De Laval latest type oil purifiers.

She carries 24 passengers in beautiful rooms on the promenade and boat decks. Each of the eleven rooms has its private bath and is equipped with a bed and a Pullman berth that folds into a comfortable couch for day service. At the forward end of the promenade deck is the lounge, which is one of the most charming rooms we have seen on shipboard. The illustration and the deck plans herewith show the graceful shape of this apartment and some idea of the indirect lighting effects. In addition to line and proportion this room has hardwood paneling that is a masterpiece in ship joinery, and is furnished and carpeted in a very strikingly harmonious color scheme. It is separated from the vestibule by a fine etched glass bulkhead.

The dining room on the shelter deck level is another lovely room with normal seating for 24. On the starboard side is the chief steward's office and bedroom, on the port side, the office and bedroom of the ship's doctor.

The decor on this vessel impressed us as being harmoniously modern.

On the boat deck level, under the pilot house, are two luxurious suites, one for the owner and the other for the captain.

A notable feature of all new Johnson Line ships is that they carry stainless steel propellers, and on at least one vessel the propeller has an adjustable, or reversible pitch.

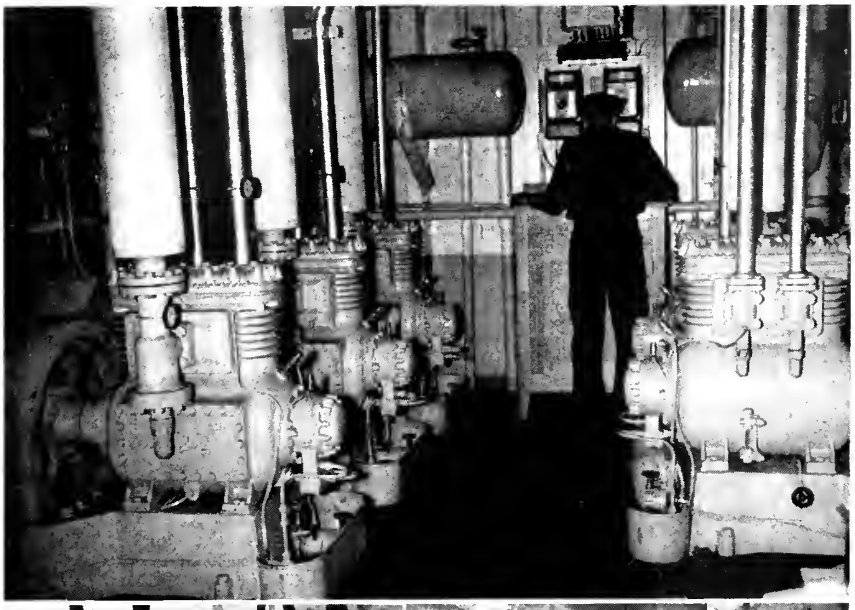
Bio-Bio is just one example of the modern cargo-passenger liner that Swedish yards are now building. Here are some more examples of that and other types.

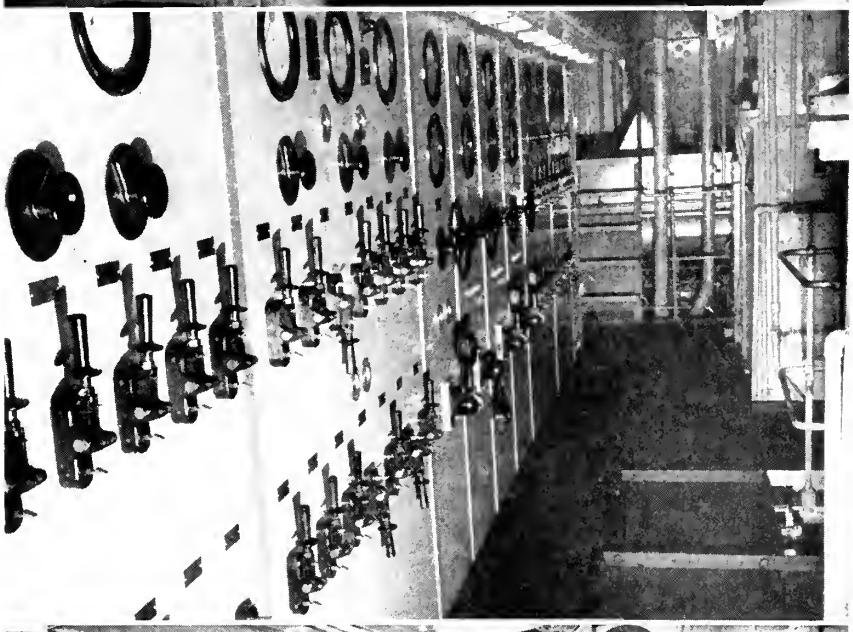
In the middle of December the Eriksberg shipyard of Gothenburg delivered a motor vessel of 9,160 tons d.w., the MS. Mongabarra, to the Transatlantic Shipping Company of Gothenburg.

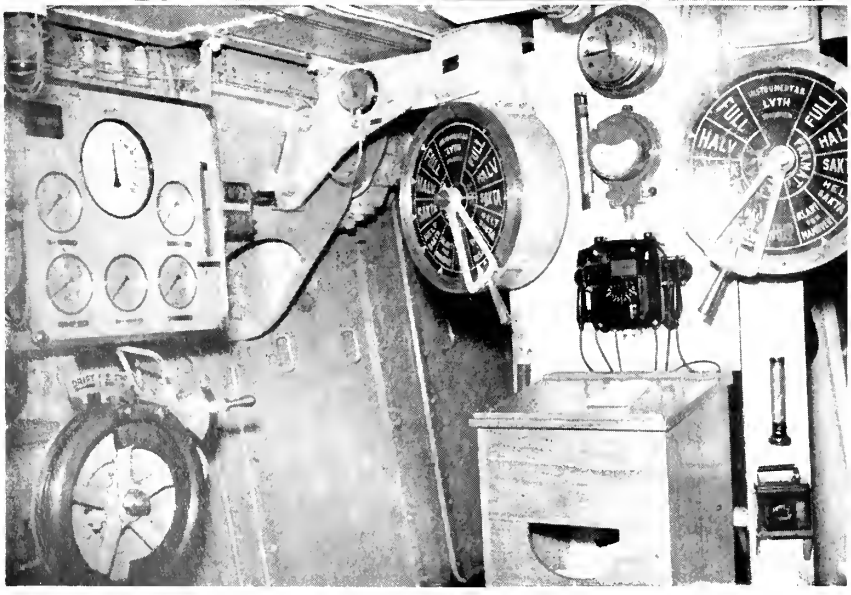
The vessel, which is of the modern shelter deck type, has been built to Lloyd's highest class. Her main dimensions are: length between p.p. 405′-0″, molded breadth 56′-6″, depth to main deck 28′-9″ and depth to shelter deck 38′-9″. She has four cargo holds and deep tanks for about 1,000 tons of oil. There are six passenger cabins, each with a bathroom. The officers are accommodated amidships, while the crew's quarters are situated aft. Officers as well as crew have special day rooms at their disposal. The propelling machinery consists of a two-stroke single-acting directly reversible solid injection diesel engine of Eriksberg's own make, developing 5,400 ihp and giving the ship a speed of 14 knots on full cargo.

At about the same time the Lindholmen shipyard of Gothenburg delivered the motor cargo vessel Yvonne, 5,800 tons d.w., to the Disa Shipping Company of Stockholm.

This vessel too is a shelter decker and built to the highest class of







Upper left: Five sets of refrigeration compressors.

Center left: Electrical switchboard in engine room.

Lower left: Port main diesels starting platform.

Lloyd's. The main dimensions are: over-all length 441'-1", molded breadth 53'-0" and molded depth to main deck 25'-0". Yvonne is provided with six cargo holds, one of them equipped with refrigerating system. Passengers as well as officers and crew have very comfortable accommodations at their disposal. A spacious dining room and a promenade deck and a veranda-cafe are among the passenger facilities, and every cabin has its own bathroom. The officers are accommodated in the deckhouse amidships, while the crew are quartered aft in single berth cabins. The vessel is propelled by two 9-cylinder two-stroke single-acting directly reversible solid injection B & W diesel engines of Eriksberg's make, each developing 3,150 hp. at 160 rpm, giving the ship a speed of 17 knots.

The same yard recently launched a motor cargo vessel of about 3,000 tons d.w. for the Diana Shipping Company of Stockholm. The propelling machinery, which is placed aft, will consist of an 8-cylinder two-stroke directly reversible Polar diesel engine, developing 1,310 at 250 rpm.

The Gotaverken shipyard of Gothenburg launched at the end of December a motor liner of 7,300 d.w., the Rydboholm, for the Swedish American Mexico Line (Brostrom Concern) of Gothenburg.

The new vessel, which is a sister ship of Stegeholm and Vretaholm, delivered by Gotaverken to the same owners in 1939 and 1943, respectively, is welded to a large extent and has welded corrugated bulkheads according to Gotaverken's system. She has accommodations for a small number of passengers, and will be propelled by a two-stroke single-acting

diesel engine of the yard's own make, developing 8,300 ihp at 112 rpm.

In the middle of December the Gotaverken yard launched a new ore carrier of 6000 tons d.w., the Karesuando, for the Grangesberg Company of Stockholm. This ship is the last one in a series of 12 vessels built by Gotaverken for these owners during the last three years.

The Eriksberg yard, also of Gothburg, launched a motor cargo vessel of 3650 tons d.w. for the Swedish Lloyd Shipping Company.

In the middle of November the Oresund shipyard of Landskrona launched a motor tanker of 15,500 tons d.w., the Avanti, for the Fraternitas Shipping Company of Gothenburg.

Early in December the Gotaverken yard delivered a motor tanker of 17,300 tons d.w., the Kim, to the Stenersen Shipping Company of Oslo. This company, however, has sold the vessel to the Argentine government-owned shipping company, Yacimientos Petrolificos Fiscales of Buenos Aires, which will name the ship San Antonio. The vessel, one of the biggest so far built by Gotaverken, is a sister ship of Julius, Constance and Buenos Aires.

Improved Post-War Danforth Anchor

A new Danforth anchor, the Mark IV, is now in production. This improved Danforth is planned in all sizes from 5 lbs. to and including sizes for the largest ships.

Judging from advance reports this improved post-war model is destined to create as great a revolution in the art of anchoring as the current Mark II, introduced some years ago.

The new Danforth is made of heat-treated high tensile alloy steel forgings and rolled steel sections with a tensile strength of over 150,000 lbs. as compared to 57,000 for ordinary steel.

Preliminary plans for the new anchor were developed several years ago but it was not possible to manufacture in quantity during the war, as the special steel required was not available for anchors. However, a number of experimental anchors were made and tested extensively by fishermen, pleasure boat owners and the manufacturer in actual service. For example, a 5-lb. Mark IV in service aboard a 40-ft. cruising sloop held this craft satisfactorily in all types of bottom, including soft mud six feet deep, in measured 25-mile winds. It is the opinion of the manufacturer that a 10-lb. Mark IV would furnish safe holding power for a boat of this size under almost any conditions.

The increased strength of the high tensile steel makes it possible to manufacture the new Danforths in the same dimensions but approximately half the present weight. Example: the 30-lb. Mark II "size" weighs only 17 lbs. in the new Mark IV.

All parts are thinner and stronger. This further streamlining decreases resistance to burial so that the new Danforth Mark IV digs in even faster and holding power per pound of anchor is substantially increased.

The cost of the material used is more expensive per pound, but it is so much stronger and lighter that less material is required to secure equivalent holding power. The net result is a reduction in the cost for Danforths in sizes necessary to do a given job. This means a better and more efficient product at lower prices to the consumer.

The following are a few comparisons of the tested holding power of

Admiralty Decisions

By Harold S. Dobbs
of the San Francisco Bar

Misfeasance (1) Vs. Nonfeasance (2)

Sometimes the layman has difficulty in understanding why the general agent may be held for tort liability in one case and, under what appears to be the same set of circumstances, released in another. One of the answers to the question is graphically illustrated by the case of **Pipitone, Plaintiff, vs. Standard Fruit & Steamship Co., Defendant,** State of New York, Supreme Court, Trial Term, Kings County, May 17, 1945.

Plaintiff, an employee of an independent ship repair contractor, in the course of his duties was injured aboard the steamship Henry Groves Connor in the Port of New York. The vessel was owned and operated by the United States and assigned to defendant Standard Fruit & Steamship Company under the terms of a General Agency Agreement (G.A.A. 4/4/42). The action was brought in the New York Supreme Court, County of Kings, against the General Agent. Admittedly the port boom of No. 4 hatch fell, injuring the plaintiff, while it was being topped by riggers employed by the independent contractor. Upon conflicting evidence the jury found that the boom fell because of a worn and defective shackle by which the topping lift was made fast to a pad-eye in the deck. The negligence charged was that the defendant General Agent had failed to equip and maintain the vessel (G.A.A. Article 3A (c) and had failed to inspect and arrange for the repair of the vessel (G. A.A. Article 14) and negligently permitted the vessel to become unseaworthy. At the close of the plaintiff's case and of the whole case, defendant moved for a directed verdict and for the dismissal of the complaint. The Court reserved decision on the motions and submitted the question to the jury, who returned a verdict in plaintiff's favor in the sum of $25,000.

(1) Misfeasance: (a) A wrongful act; (b) The improper performance of some lawful act; (c) negligence.
(2) Nonfeasance: An offense of ommission.

The Court very aptly stated that there could be no question but that the relationship between the United States and this defendant was that of a principal and agent (**Pederson vs. Stockard,** 1945 A.M.C. 23, 51 N.Y.S. 2d. 675). That being so, the defendant was not liable to third parties for nonfeasance but only for misfeasance. It is not always easy to determine under which category the alleged negligence arose, but the determination of that question goes beyond consideration of the mere affirmative or negative allegation of the same charge, i.e., "The defendant failed to conduct himself as an ordinarily careful and prudent person, etc." or "the defendant conducted himself in a careless and negligent manner, etc." There must be an actual active intrusion upon the rights of a third party by the agent to make him liable. Thus, if this defendant had furnished a defective shackle, and by its act had created a dangerous condition, it would be liable, whereas, it is not liable for failure to remedy a condition which it did not create. Failure to inspect, repair or replace is nonfeasance, and herein lies the differentiation between this case and that of the Pederson case upon which plaintiff leans so heavily. In the Pederson case the Appellate Division of this Department said, "Here the agent's responsibility required it to **furnish** appliances suitable for the work they were designed to perform and free from defects." Of course, the furnishing of an inadequate or defective appliance would be a misfeasance, because it would be an act which created the dangerous condition precipitating the accident. Defendant's motion is granted. The verdict of the jury is set aside and the complaint dismissed.

Wholly-Owned Government Subsidiary Cannot Recover Against Another Wholly-Owned Government Subsidiary

A most important decision from the standpoint of the underwriter has been followed again in **Defense Supplies Corporation, Libellant, vs. American-Hawaiian Steamship Company, Respondent, and United States of America, Respondent-Impleaded,** U. S. Dist. Ct., Southern Dist. of New York (1945 A.M.C. 1300). In that case the libellant, a wholly-owned subsidiary of Reconstruction Finance Corporation, shipped a cargo in the steamship Minnesotan and insured it against usual marine cargo risks. The Minnesotan was under Time Charter, Form 101, to War Shipping Administration. The cargo was damaged and the cargo underwriters caused a cargo damage suit to be filed against American-Hawaiian S. S. Co., as owner of the Minnesotan, in the name of the assured, Defense Supplies Corporation. The American-Hawaiian Co. impleaded the United States as a party respondent, alleging certain provisions of the charter party and also certain indemnity clauses in the Time-Charter-Agency Agreement under which the steamship company

acted as Agent for W.S.A. Thereafter the proctors for Defense Supplies Corporation made a motion to intervene on behalf of 12 cargo underwriters participating in the loss.

The Court follows the sound authority of **Defense Supplies Corporation vs. United States Lines Co., et al.,** (1945 A.M.C. 423, 148 F. (2d) 311) (Cert. denied, U. S. Supreme Court), (1945 A.M.C. 1387), wherein the Court made a finding that if one subsidiary of the Government were allowed to recover against another subsidiary, the Government would be in effect taking its money out of one pocekt and putting it in another. In the instant case, 12 insurance companies ask leave to intervene as subrogees of the libellant, Defense Supplies Corporation. The respondent, American - Hawaiian Steamship Company, is the owner of the steamship Minnesotan, which was under time charter from the owner to War Shipping Administration at the time the libellant's goods were damaged. The respondent has impleaded the United States of America.

The libellant is a corporation, completely owned by the Reconstruction Finance Corporation, a Government agency. Hence, this admiralty suit **in personam** is in effect a suit by the United States against the United States, and under the authority of **Defense Supplies Corporation vs. United States Lines Co.,** cannot be maintained. The insurance companies which seek to intervene would have no better rights as litigants herein than their subrogor, the libellant. Hence, to grant this petition for intervention would be futile.

The motion for leave to intervene is accordingly denied.

The principle of this case as well as the first Defense Supplies case certainly works to the ultimate advantage of the underwriters in that they are completely relieved of liability, provided each of the parties to the claim is a wholly-owned Government subsidiary. Of course, under ordinary circumstances a different result would follow.

Steamship Owner's Rights Under Special Appearance

In the case of **William F. Lenz, Libellant, vs. Sudden & Christenson, Inc., Respondent** (U. S. Dist. Ct., Eastern Division of Pennsylvania, in Admiralty, 1945 A.M.C. 938), the sole question involved is whether a respondent who is challenging the jurisdiction of the Court may be required to answer interrogatories pertaining to the challenged jurisdiction. In this case the libellant is seeking wages, penalty, maintenance and cure through the medium of an "in personam" action in admiralty. In this case, service of the Citation and Libel in personam was made by leaving a copy at the office of the Waterman Steamship Corporation as agent of the respondent. The respondent then appeared specially and moved to vacate the service upon the following grounds: (1) that it is a California corporation and its principal office and place of business is San Francisco, California; (2) that it is not registered to carry on business in the Commonwealth of Pennsylvania and has not engaged in business in said Commonwealth; and (3) that it does not maintain an office or place of business within the Commonwealth of Pennsylvania.

The libellant filed an Answer to the Motion to Vacate Service, admitting that the respondent is a California corporation, but averring that it has been, and is presently, engaged in doing business within his district and further that the respondent by its duly authorized agent (Waterman Steamship Corporation) has maintained a place of business within his district. Subsequently, the libellant propounded a series of interrogatories which it contends is designed to throw light on the question of whether the respondent is carrying on business within this district by a duly authorized agent. The respondent in turn filed Exceptions to these interrogatories, contending that it is not an adverse party within Rule 33 of the Federal Rules of Civil Procedure.

The Court leans heavily on the authority of **Tradesmens National Bank and Trust Company, Executor, Etc., Plaintiff, vs. Charlton Steam Shipping Company, Ltd., et al, Defendants** (1944 A.M.C. 475) (April, 1944), which holds that a libellant is without right to propound interrogatories to a respondent who had appeared specially to deny jurisdiction. The Court in the Tradesmens case said:

"Where a corporation named as a defendant in an action has challenged the jurisdiction of the court to entertain the action against it on the ground that it has no property or agents in the jurisdiction and is not doing business therein, it is difficult to see how it may be considered as an 'adverse party' within Rule 33 so as to be required to answer under oath interrogatories served upon its alleged agent or, in the alternative, be subject to the penalties prescribed by the rules for refusing to answer."

For the reasons stated, the respondent's Exceptions to Interrogatories must be sustained, and it is so ordered.

The libellant, however, is free to utilize the remedy afforded by Rule 26 (a) of the Federal Rules of Civil Procedure, which provides for the taking of depositions in a situation such as exists here. In **Jiffy Lubricator Company vs. Alemite Company et al** (23 Fed. Supp. 385), the Court specifically stated that where the question of jurisdiction had been raised (page 386) "* * * it would seem that it is within the spirit and intent of the new rules, under these circumstances, to permit the Court to authorize the taking of depositions which are limited to the question of jurisdiction raised by defendants' motion * * *."

The William F. Fitch, Army Repair Ship

By George H. Harlan

(All photos Official U. S. Signal Corps Photographs)

THE PACIFIC WAR required repair facilities for troopships and troop supply vessels at points much closer to the fighting areas than those which already had repair facilities. The latter were already overloaded with work as well as being remote from the scenes of combat. The Army's answer to this problem was the outfitting of five repair ships and three repair barges, eight units in all, and all equipped to make major repairs to all types of vessels wherever they may be. Realizing that the military operations would change from locality to locality in the island warfare, the Army chose to build these mobile repair yards rather than build up permanent shore installations in places that might become removed from the battle-fronts before a repair yard could be completed.

The five repair ships consisted of shops and stores which were operated by repair gangs carried by the ships themselves. The three repair barges were mere floating repair shops, carrying no stores or crew, but were operated by short based crews and stores sent as required from central operating depots.

To describe the ships more adequately, the William F. Fitch will be taken as an example. She was typical of the five and was outfitted by the Marine Repair Shops of the San Francisco Port of Embarkation. Built in 1902 by the Detroit Shipbuilding Company, the Fitch was, like her sister repair ships, a Great Lakes ore carrier. Transferred to the Gulf, the Boland Machine Works of New Orleans, La., transformed her into an ocean-going cargo vessel, and she went into service as such for the Army until she was commandeered for repair ship duty.

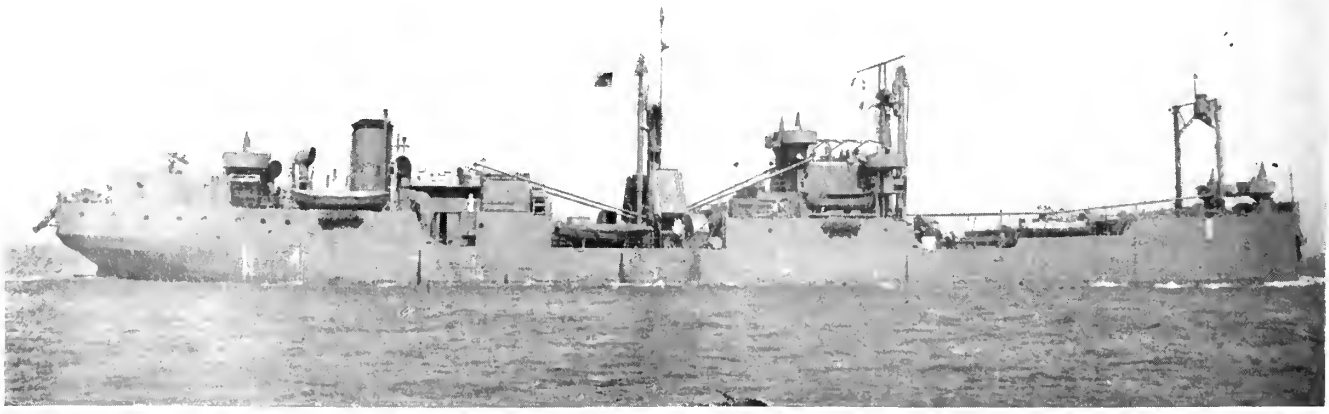
The Fitch is a steel deck freighter of four hatches. Her wheel house is on an island house between hatches Nos. 2 and 3, and her machinery is aft. She has a small triple expansion engine and two small Scotch marine boilers of the single end type, and is capable of doing about eight knots. This is adequate speed to propel her from frontier base to base.

Principal Characteristics of the U. S. A. R. S. William F. Fitch

L. O. A.	353′ 8″
L. B. P.	346′ 0″
Breadth	48′ 0″
Depth (Molded)	28′ 1″
Gross Tonnage	3982
Net Tonnage	2859
Main Engine	Triple Expansion
Size	22″ x 35″ x 58″ / 42″
I. H. P.	1550

The three decks which were extensively altered were the Main Deck, 2nd Deck and Holds. At the forward end of the Main Deck and adjoining the Fo'c'sle Deck was built housing for oxygen and acetylene bottles for the welding apparatus. Although electric welding was used by the repair ship's welders, the older style was also employed where repair parties were unable to work close to the ship's electrical supply. Hatches Nos. 1 and 2 were cut down in size and a large working platform 35′ 0″ x 48′ 0″ was provided be-

Girded for war work by the San Francisco Port of Embarkation, D & C's William F. Fitch bears little resemblance to the grain and ore carrier that sailed the Great Lakes for over 30 years.



tween the two. This platform was of sufficient area to enable large projects to be worked on by many men of all crafts at one time. When the ship is under way, the platform provides stowage for the ship's barge, duck (seagoing Army automobile), and jeep. The barge was of steel construction and sectional. Its two sections could be locked together, and as both were 9′ 0″ x 40′ 0″, when assembled they made a barge 18′ 0″ x 40′ 0″. This barge could be used as a place from which to work on ships' sides or where a floating scaffold had to be employed.

Aft of No. 2 Hatch and forward of the island house was the mast for the 50-ton boom. The mast was stepped on the tank top and stood 45′ 0″ above the Main Deck. The 50-ton boom was stepped on deck at the base of the mast and had a reach, at a good working angle of 45°, to the center of the working platform. The boom was used to handle the ship's barge and to lift aboard any small boat to be repaired which might weigh 50 tons or less. This lifting gear had an 11 part topping lift and 10 part hoist, both composed of 1 1/8″ 6 x 19 wire rope. Blocks were shackled onto links with square cross sections to prevent twisting of the multipart purchases. Steam winches for this boom developed a line pull of 13,500 lbs.

All hatches were provided with 5-ton booms. As a freighter the Fitch had a 30-ton boom at No. 4 Hatch. This was left to handle any heavy loads to the machine shop below, and to handle the 26′ 0″ towing mine yawls which were kept abreast of No. 4 Hatch. These small diesel driven craft were used to tow the ship's barge, and were used as the ship's launches to make physical contact with ships to be repaired. On the stern of the ship a large steam driven winch was placed, and 1000 feet of 1 1/8″ wire cable was stowed on the drum thereof. This winch served a threefold purpose. It could handle mooring lines about the stern of the ship, its cable could be attached to the stream anchor when such was necessary, or it could be used as a towing engine for towing small craft. There being no place on deck to stow the stream anchor, this article was stowed on a pipe rack on the stern of the ship.

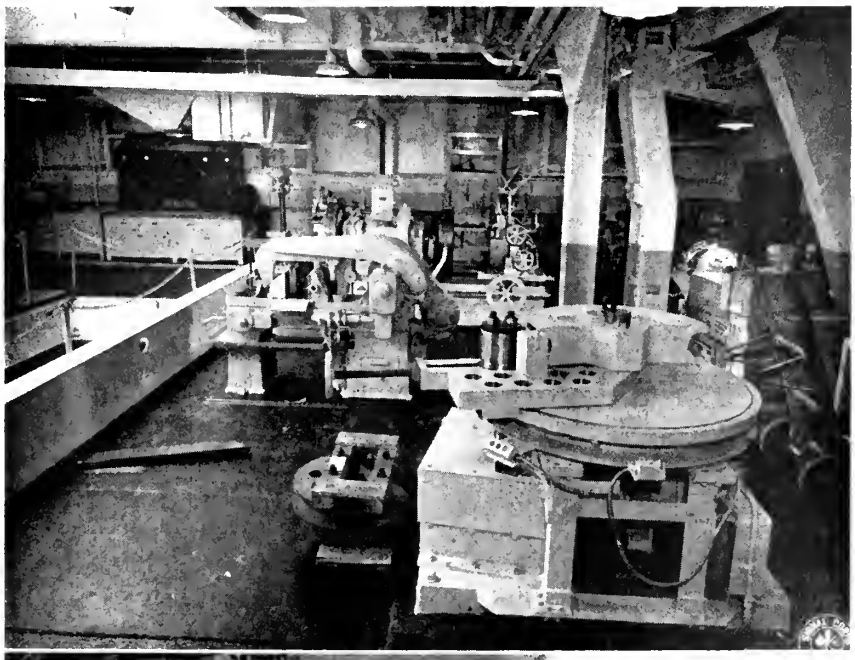
The repair shops were located for the most part on the 2nd deck. Up forward in No. 1 compartment was the Carpenter Shop. Woodworking

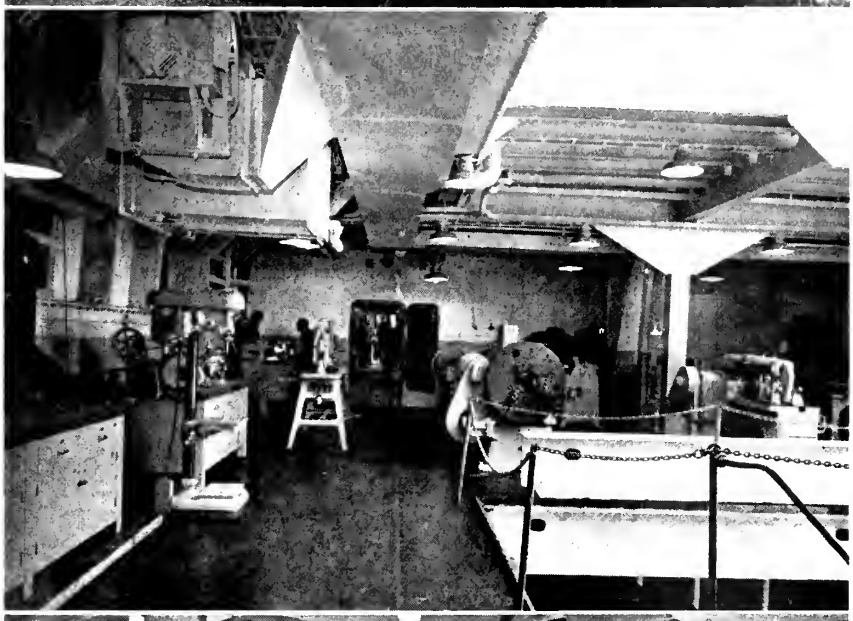
Army marine ship repairman operating 14-ton machine lathe aboard a Transportation Corps vessel operated by the San Fancisco Port of Embarkation.

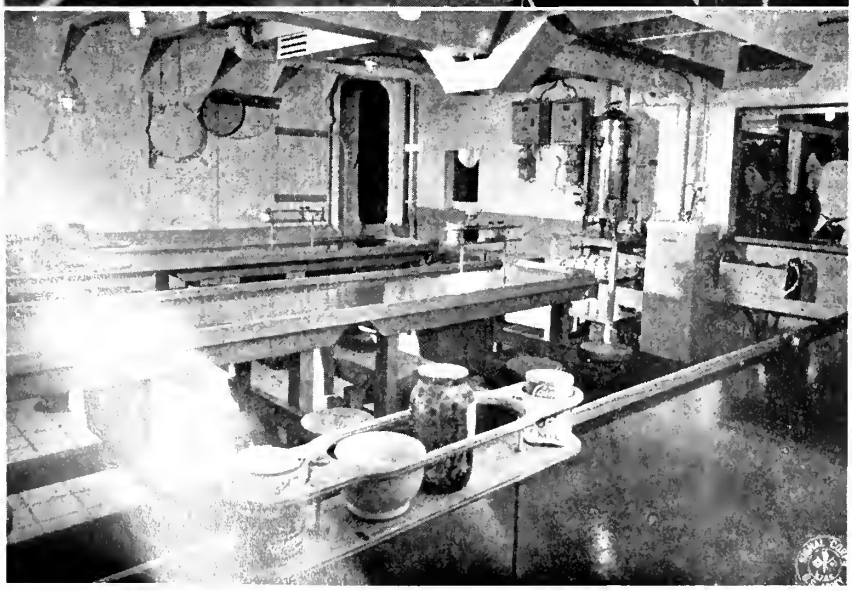
equipment, both hand and machine, were provided in as complete an array as could be found in any first class joiner shop. On the port side was the DeWalt circular saw with roller conveyors extending from the forward to after bulkheads of the compartment. At the forward end of the compartment was a pitch heater. Aft of the hatch were benches and tool cabinets, a large band saw, an arbor saw, a tilting arbor saw, a hollow chisel mortiser, a bench grinder and a saw blade cabinet. On the starboard side was a planer, a woodworking lathe, a joiner and a drill press. Up on the main deck, under the working platform, were three steam boxes to prepare wood for shaping. The steam boxes were made out of former torpedo tubes from World War I.

In No. 2 compartment were the Shipfitters, Blacksmith and Sheet

Sheet Metal Shop.



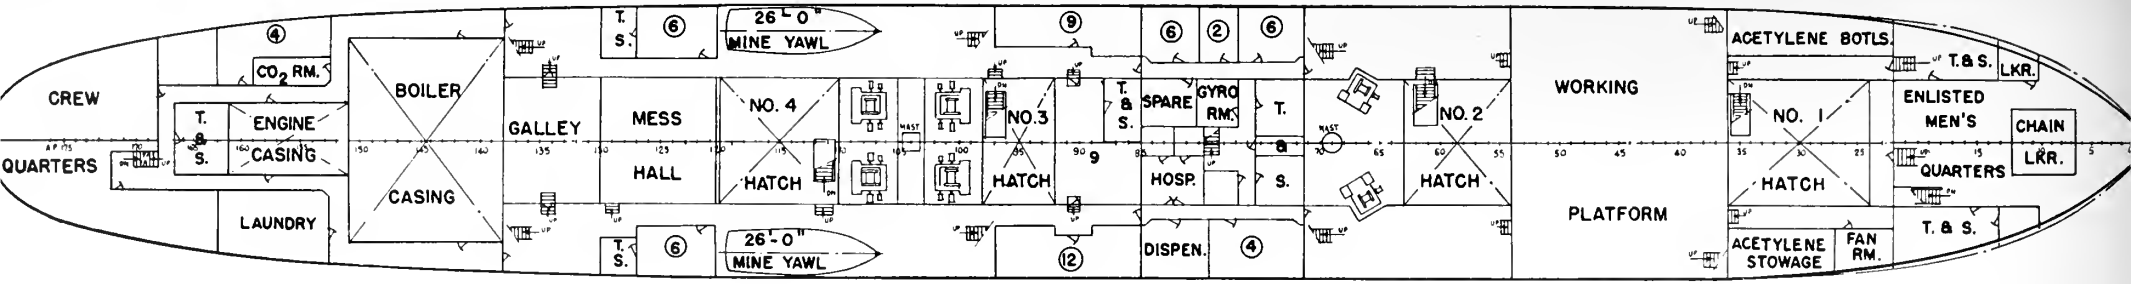




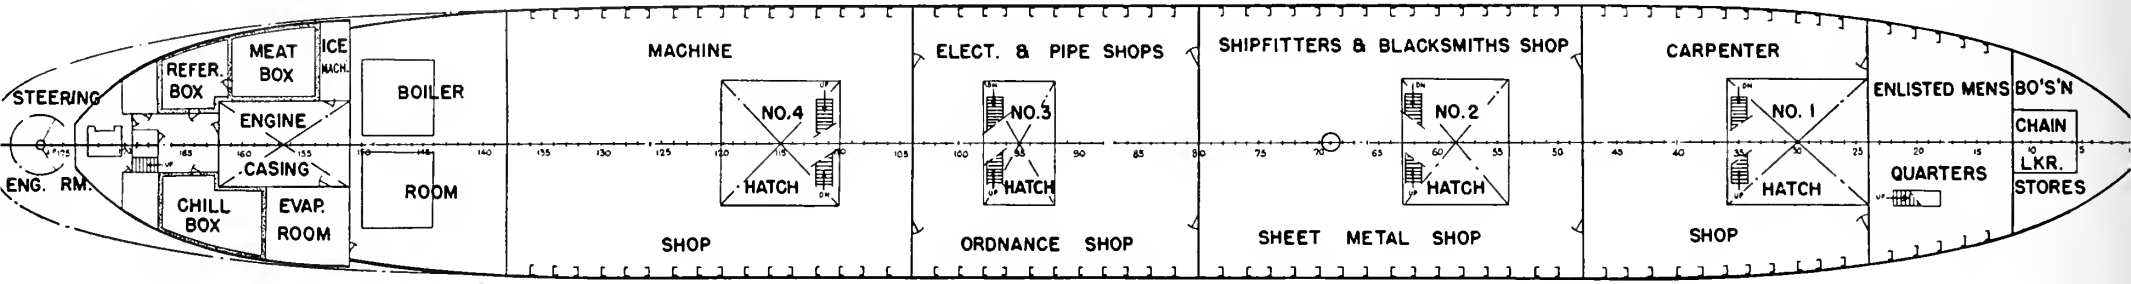
Metal Shops. The Shipfitters' Shop was located on the starboard side aft. Most of the space was taken up by a large bending slab, 10′ 0″ x 15′ 0″. Next to it was a plate roller which could accommodate any plate size up to ¾″ There were also a slip roll hand forming machine, welding sets, and two portable electric welding machines. Overhead was a monorail system to simplify the handling of large steel stock. On the portside of the compartment at the after end was the Blacksmith Shop. This contained a forge (6″ sq. open.) with quenching tank, an iron worker, anvils, a large grinding machine, a power hammer and cutting machine. All equipment necessary to do any kind of blacksmith work was present. One of the disadvantages of the ships, however, was that none of them possessed foundry equipment, and this proved to be a hindrance at times. In the forward end of No. 2 compartment was the Sheet Metal Shop, which contained a combination roller, bending, and box brake; a power shear and squaring shears, rotary shears, an angle iron combination machine and a soldering iron furnace.

The Electric Shop, Pipe Shop, and Ordnance and Signal Corps Repair Shops were in No. 3 compartment, 2nd Deck. The Pipe Shop occupied the space forward of the hatch. It contained a cutting saw capable of handling anything up to 10″ pipe. There were also two pipe threading and cutting machines, one for the smaller sizes up to 2″ and a larger one to handle the intermediate sizes up to 6″. Tool racks, benches, and a Pedrick pipe bending machine of 4″ pipe size capacity rounded out the power tools in the pipe shop The electric shop was on the port side and contained a test panel, wire reel rack, a coil former, a buffer, an armature winder and an armature press. Various tool cabinets and benches constituted the remainder of the equipment of the electric shop, as well as a battery charger and a bake oven. An overhead monorail facilitated the handling of large generators and motors. On the starboard side the Ordnance and Signal Corps had shops capable of repairing guns, radio equipment and radar. Most of the tools in this shop were small precision machines. The larger power

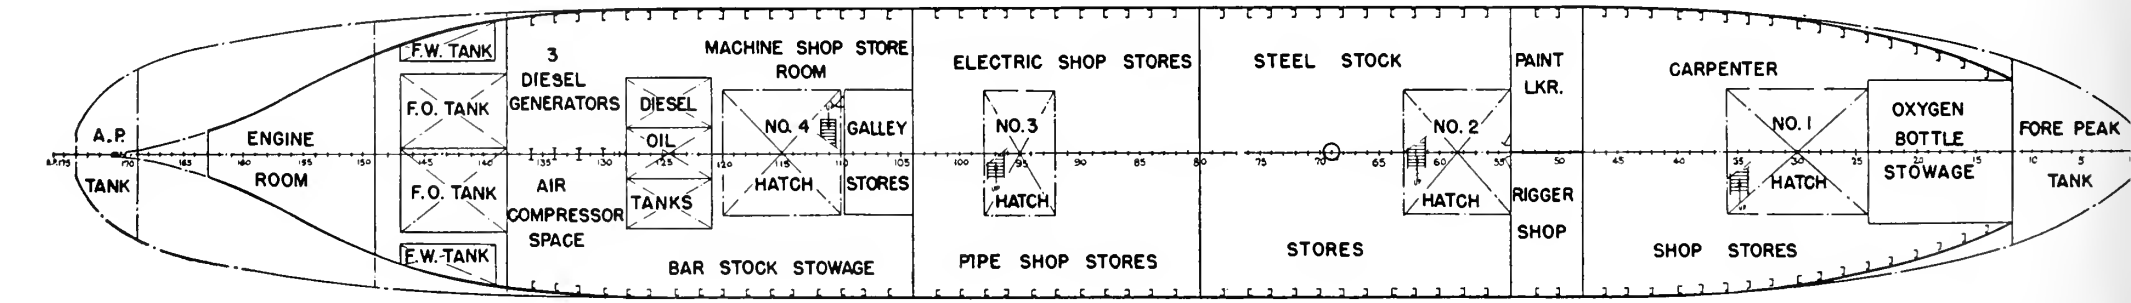
The top and center pictures show the Pipe Shop; the bottom shows the crew mess.



MAIN DECK



2ND DECK



HOLDS

Drawings showing arrangement of repair facilities on the William F. Fitch

tools consisted of a 9" lathe and two drill presses. Any larger work could be handled by machine shop equipment in the next compartment.

The Machine Shop in compartment No. 4 was the largest installation on the William F. Fitch. Its quantity and size of power tools would be the envy of many a shore installation. All four of her sister repair ships and the three repair barges were equipped with shops of equal magnitude. A heavy duty engine lathe, 26' 0" long, was the largest tool in the shop, although a giant shaper and a 4' 0" radial drill were not far behind in size. There was an 80-ton Manly hydraulic press, a toolmaker's lathe, a 13½" lathe and a 16" lathe. In addition to this battery of lathes there was a precision lathe. There was an adjustable stand for overhauling engines, this stand not only capable of being adjusted to fit the engine under repair, but also tilting in any direction to facilitate work on any isolated part of the engine. There was a small precision shaper, a Do-All saw and a universal milling machine. There were a Norton cutter and grinder, a tool grinder, and an internal grinder. There were a babbit furnace, a 3-ton arbor press and a 100-ton wheel press. Major Norman R. Gindrat of the Marine Repair Shops at Oakland Army Base takes great pride in the construction of the latter machine. He made his first hydraulic press for the Oakland Shops out of scrap iron and junk. It was so successful that he stood ready to make all the presses needed for the repair ships and barges, and he was permitted to fill the order. He improved upon his original machine, and the result was a class "A" wheel press which saw plenty of service on every vessel on which it was placed. Tool cabinets and benches line the machine shop, and all heavy machines were served by an overhead monorail system. This floating repair shop proved to be an eyeopener for many a mariner with a ship which was a casualty up at the front lines. Machining, electrical and pipe work, joiner work, gear repair, and radio repair, no job was too big for the Fitch to handle. Some tools, of course, saw more service than others, some were worked day and night, others hardly at all. But each had its advantages and limitations, and each helped to make the Fitch into one of the most versatile repair ships afloat.

In No. 1 Hold, at the forward end, were stowed additional oxygen bottles. The remainder of the hold was devoted to the storing of lumber, all kinds, heavy timbers, light boards, plywood, etc., and all varieties from pine to oak. There was also storage bins in No. 1 Hold for nails, hardware, screws, bolts, and all other odds and ends of stores necessary to keep a floating carpenter shop running. All stores, wherever possible, were located directly below the shops which used them. The ship's cargo gear could lift them to the decks where used as needed.

In the forward end of No. 2 Hold was the Paint Locker on the port side and the Rigger's shop on the starboard side. The paint locker accommodated all paints for ship's service and repair work. The Rigging Shop was a storage place only, for all rigging work was done out on the working platform or in the machine and blacksmith's shops. The rest of No. 2 Hold was devoted to sheet metal, steel shapes and plate stowage. Because of the concentrated weight of these stores, the hold was not completely filled with stock, a load limit per square foot of floor space being imposed.

In No. 3 Hold, which was directly under the Pipe Shop, were stored all the pipe lengths. In bins on each side of the hold were kept the pipe fittings, other pipe shop supplies and electrical supplies. In No. 4 Hold forward was kept the bar stock for the machine shop, spring wire, tool steel, piston stock, etc. Just forward of No. 4 Hatch was the galley dry store space. Aft of the hatch were three deep tanks, not extending full thwartship, these tanks being storage space for diesel oil. Aft of the tanks was the motor room for the repair shops. It contained two air compressors and three diesel driven generators. The air compressors were Ingersoll-Rand two stage compressors which delivered 156 cfm each at 100 lbs. pressure. The three generators were 50-kw capacity, producing alternating current. At the time that the repair ships and barges were designed it was almost impossible to get large machine tools with direct current motors; hence it was deemed advisable to make the entire ship alternating current with the exception of the few direct current motors which were already aboard and which constituted only a small portion of the load. Two new small turbo generators in the engine room took care of the entire D. C. load, for one could handle it alone with the other as a stand-by.

The operation of the ship itself was handled by a Coast Guard crew. The Repair Company aboard the Fitch was the 801st Army Marine Ship Repair Company. It was composed of officers and enlisted men who operated its extensive shops. The enlisted men were top craftsmen and made special application to the Army for the jobs. Taken from civilian life, these men were given basic training and then sent out to sea on a repair ship. Ratings were given not on their military proficiency but on their skill in their respective crafts. Many of these men would ordinarily have been drafted into the artillery or infantry, but in repair companies were able to serve in their own special line in places where they were most needed. The repair companies were composed of 114 men, and the ship carried 80 additional persons as crew members. As enough water could not be carried to serve this group, a 12-ton low pressure evaporator was installed to take care of their needs.

Whereas the repair ships could operate as a unit, and were a complete shop with men and material for operation, the repair barges were just floating shops. The barges worked out very well when used in conjunction with a floating drydock and a supply barge, anchored offshore at some frontier base. Both the repair ships and barges had over $1,000,000 worth of machinery and equipment aboard. They were able to serve the frontier of remote islands as it could never have been otherwise served. They repaired disabled ships which would have either had to be towed hundreds or thousands of miles for repair or be left at the front. They repaired ships which were damaged but not disabled which might have been disabled had they had to make the return journey in their damaged condition. Army, Navy, Coast Guard or merchant ships, they all looked alike to the repair companies. They were all attended to as needed by the Pacific Command.

Peak Diesel Performance Demands Quality Engine Accessories

By Walter C. Bauer

To maintain a diesel engine at its peak performance there are a number of operational characteristics that must be kept normal. The major of these items are:

(1) Controlled cooling
(2) "Tight" engine
(3) Free piston rings
(4) Adequate clean lubrication
(5) Perfectly operating injectors
(6) Proper injection timing
(7) Clean, high-quality fuel
(8) Intake air cleanliness
(9) Engineered exhaust system
(10) Efficient and reliable instrumentation.

Controlled Cooling

The proper control of diesel engine cooling demands more than a thermometer on the cooling water outlet. The diesel engine is defined as a "compression ignition engine". The air that is compressed in the cylinder reaches a sufficiently high temperature to ignite the fuel as it leaves the injection nozzle. Obviously the hotter this compressed air, the less time lag for the fuel to start to burn and the smoother becomes the combustion. To maintain peak performance, this compression temperature should be constant under all conditions of load. In fact, it should be hotter under light engine loads—when very minute quantities of fuel are injected — than under full loads, when large quantities—and more easily ignitable quantities — of fuel are admitted. The head of the piston usually comprises about 40% of the surface of the combustion chamber. In modern diesels the piston is almost universally oil cooled. The piston coolant temperature then should be maintained constant.

There is a temperature gradient from the combustion chamber to the cylinder water jacket that is quite high. To maintain a constant or cooler compression temperature under heavy loads than exists under light loads requires a considerable variation in jacket coolant temperatures. Coolant circuit diagram (1) illustrates how this can be done reasonably well automatically with a somewhat different arrangement of heat exchangers in a closed cooling system.

This system requires much larger heat exchangers than those normally supplied with the engine, but results obtained over rather long periods of time have well justified the expense where this system has been installed.

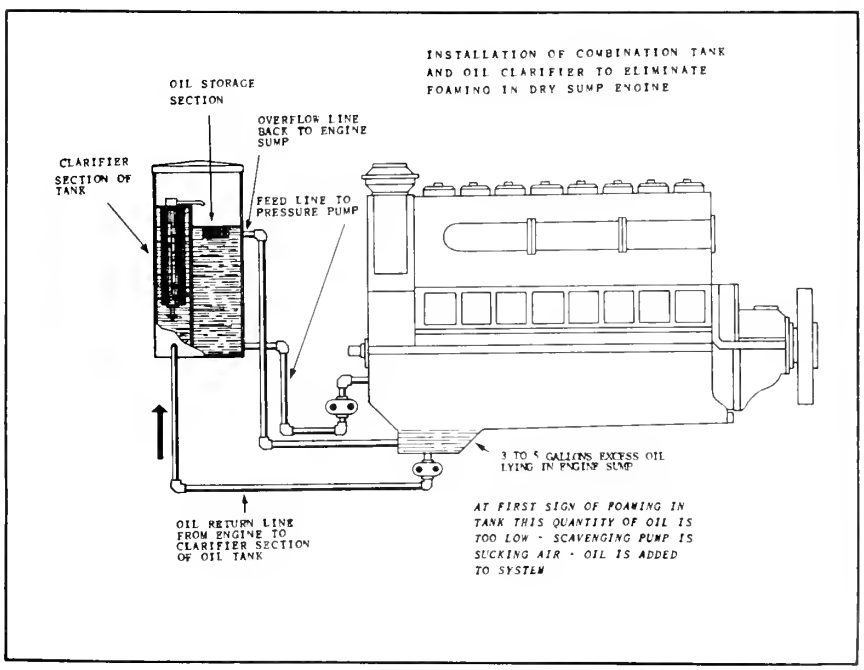
"Closed" cooling systems—systems where treated clean water is used to cool the engine—and raw water only enters the heat exchangers—is almost a must for efficient diesel engine operation. By this system a large quantity of water can be circulated through the cylinder jackets, hot or cold spots eliminated, water jackets remain free of mud or lime deposits and engine cooling maintained at its peak indefinitely.

Tight Engine

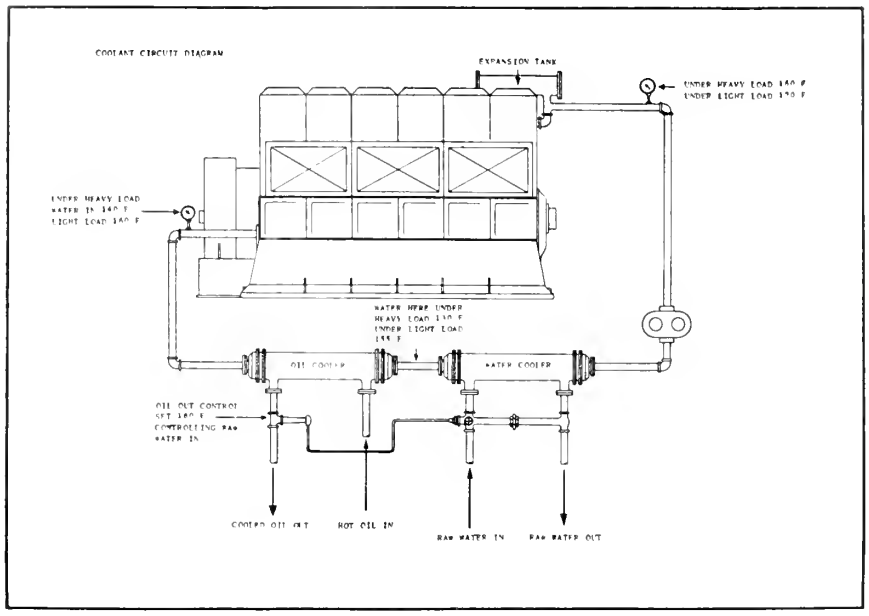
Webster defines "tight" as "not loose," "compactly built," "not leaky", "taut," "snug." That about describes a "tight" engine. A tight engine would have no loose or sloppy bearings, no piston slaps, no loose or clattering valves or valve gear, no loosely fitted gears in the accessory drives, no leaking fuel or lubricating oil lines, no leaking crankcase doors, no unbalanced parts to cause vibration or uneven running at peak loads and speeds. A "tight" engine is a must, if rated power and speed is to be maintained for any period of time.

Free Piston Rings

The maintenance of good piston ring condition in a diesel engine is imperative for economical power delivery. These rings are subjected to much greater punishment than is given those of a spark ignition engine. In a spark ignition engine, the fuel and air are metered to make nearly an ideal combustion mixture. There is little or no excess oxygen present and hence little or no tendency to burn the lubricant from the cylinder walls; also the compression pressures vary with the load and under light or partial loads there is reduced pressure, reduced temperature, and no burning off of the lubricant from the



(The author is Chief Consulting Engineer, The Briggs Filtration Co.)



cylinder walls. In the compression ignition engine the compression pressures are the same under all conditions of load, and only under full or nearly full load is enough fuel injected to use all of the oxygen present. Since piston ring efficiency is so closely correlated to over-all engine efficiency, the selection of piston replacement rings is one where quality alone should govern the choice.

Adequate Clean Lubrication

There is no piece of machinery where useful life is so enhanced by the use of perfectly clean oil or where the problem of maintaining the oil in that condition is as severe as in a diesel engine. The oil that cools the pistons is subjected to metallic contacts when the temperatures are well above the cracking or flash temperatures of the oil itself.

The drain down from the cylinder walls has been subjected to oxidation at extremely high temperatures. The combustion blow-by is always combustion soot-laden due to the arrest of combustion by the comparatively cool piston and cylinder walls. Should the oil not be maintained clean, these oil contaminants deposit themselves at vital spots throughout the lubrication system, restrict oil flow, seriously impair heat transfer, stick piston rings, ultimately make peak engine output impossible, and costly repairs and overhaul necessary.

It has been only during the last ten years that equipment was developed that made continuous lube oil maintenance possible. It was done by balancing absorption filtration for the removal of all visible contamination, even to soot particles, with adsorption filtration for the removal of the soluble contaminants such as the gums, resins and asphaltenes to insure really clean oil return to the system.

Constant development work and field testing has also led to the establishment of the size and volume of filtration material necessary for a reasonable operational period for the different engines and services involved. This oil maintenance equipment is again a quality "must" for peak engine performance.

Perfectly Operating Injectors

This factor is so obvious that almost no discussion of it is necessary. For each cylinder of the engine to carry its share of the load, for the full deliverance of the power in the fuel to the crankshaft, for clean engine operation, the fuel must be properly atomized. There can be no pre-leakage or after dribbling from nozzle. The pressure must be right, the opening sharp, and the cut-off clean.

Proper Injection Timing

Injection timing in a multi-cylinder diesel engine is more than just having the proper camshaft setting for injector operation. It is constantly checking the injector actuating linkage to maintain uniform clearances, to keep all control rods tight, to keep all delivery lines tight to eliminate all leakages in the fuel system, or in other words to keep the whole fuel system "snug."

Clean High Quality Fuel

A diesel engine will run on practically any liquid fuel that can be ignited by the compression temperature and that is fluid enough for the fuel system to handle. Fuel of the wrong quality can, however, cause many operational troubles and can prove terribly expensive in the long run. Ring sticking can occur from lacquering and soot formed from fuels having portions difficult to ignite and burn. High wear rates in rings and cylinder liners and bearing damage can come from similar fuels and from fuels containing excessive sulphur. Corrosion of metal fuel filters and injector parts can be the result of using fuel that has not received sufficient refining or from improper diesel fuel additives. Loss of power can come from the use of fuel having so low a viscosity that the pump seal and lubrication of injection plungers cannot be obtained.

Diesel fuel may leave the refinery a perfect product, but, due to transit contamination, arrive at the consumer's tanks in rather poor condition. This puts the burden for final cleanliness on the engine accessory fuel filters. Water, suspended rust particles, abrasive dust, zinc particles from galvanized drums, are some of the more common contaminants found in fuel oil. Water can cause rough engine operation due to faulty fuel metering, cause injector corrosion, plug fuel filters. The solid material can abrade pump plungers, plug injection nozzles, seriously impair proper atomization and cause injector dribbling.

There is also strong evidence that adsorption filtering of the fuel in use can go far to remedy injector plunger sticking, particularly in the high speed high output diesels using the lighter grades of fuel. This adsorption filtering will remove the preformed gum in the fuel which is believed to be the basic cause of this plunger sticking. Quality fuel filters, usually, a primary and secondary in series, or one large enough to combine both functions, are very necessary for continued peak engine performance.

Intake Air Cleanliness

No engineer that has ever seen

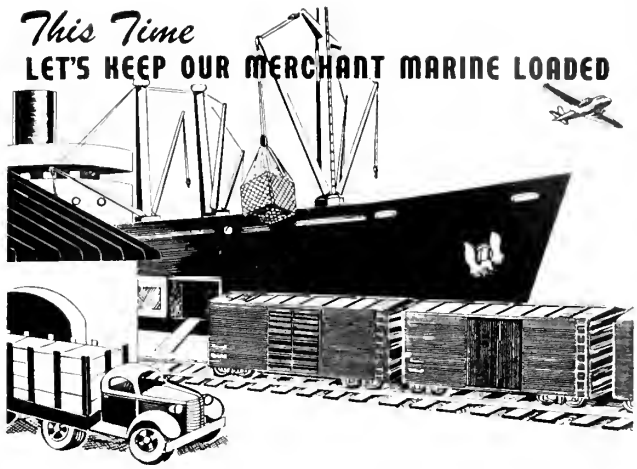
Pacific WORLD TRADE
Reg. U. S. Pat. Off.



By T. Douglas MacMullen

World Trade Institute

Nearly 400 foreign traders attended a three-day session in San Francisco last month as 50 leaders in world trade, shipping, finance and allied activities, headed by Brayton Wilbur, president Wilbur-Ellis Company, addressed sessions of the Institute of World Trade, January 24 to 26.

The series of meetings, sponsored by the San Francisco Bay Area World Trade Promotion Committee in cooperation with the Extension Division of the University of California and the Graduate School of Stanford Unversity, were designed to make available to northern California manufacturers up-to-the-minute information on entering foreign markets and conducting world trade under changing world conditions.

Panel discussions followed each address to give manufacturers the opportunity to discuss special and technical problems and assist them in establishing their foreign trade policy at this time.

At the opening session Brayton Wilbur urged manufacturers to establish their foreign policy immediately and set aside in their reconversion plans a portion of their products for foreign markets.

Dr. J. B. Condlife, Professor of Economics at the University of California, described in an opening address to Institute members the importance of world trade in our national economy.

General subjects covered were:
Direct Exporting
Indirect Types of Export Outlets
Creating Export Sales
Export Sales Promotion and Advertising.
Importing Raw Materials
Importing Consumer Goods
Transportation and Documentation
Financing Overseas Business
Marine Insurance
Controls and Restrictions
Foreign Credit, Collection, and Exchange

Copies of the "proceedings" may be ordered at $2.00 per copy from University Extension, University of California, 2441 Bancroft Way, Berkeley 4, California.

Top: Opening session of Institute of World Trade in San Francisco. Speaking is Chamber of Commerce President Brayton Wilbur.

Bottom: The panel on direct exporting. Speaking is Walter G. Perker, export manager, Marchant Calculating Machine Co. Seated, left to right: George Somerville, Atkins Kroll & Co.; Philip E. Gross, assistant export manager, California Packing Corp.; Frank Prevost, export manager, Laher Spring & Tire Corp.; H. A. Sawin, export manager, Yuba Manufacturing Co.; Gregory Lance, export manager, Erwin Paint Co.; Richard H. Steuben, export manager, Cutter Laboratories.

Creating Export Sales

By Joseph F. Marias

President

Associated Commercial Company

Export selling must never be confused with domestic selling. An exporter rarely gets the opportunity to sell his own "personality," provided he has one to sell. But, as we all know, many domestic sales are consummated because of this very thing.

An exporter then has only merchandise and service and both have to be just what the consignee wants, otherwise no business. However, it is not just as easy as that because the exporter salesmen also has foreign competition that rarely bothers a domestic salesman and so this exporter salesman must know the methods and the quality and the service of several foreign competitors and that is quite a job and it takes quite a different type of salesman.

In my own foreign experience I saw too many failures to please my American blood. Unfortunately too many manufacturers have sent successful domestic salesmen to build up their foreign accounts in the field. I do not recall many successes from these types of men. Therefore one item in the program of creating export sales is to get the right type of exporter or the right kind of foreign field representative, give him the goods and permit him to meet the requirements of the buyer by special services, if necessary, and you are off to a good start.

There are nine basic types of export selling outlets or organizations, any one of which may fit your particular needs more than any other. Briefly they are:

(1) A Full-Fledged Export Department
(2) A Built-in Export Department
(3) Combination Export Manager
(4) Export Commission House
(5) Manufacturers' Export Agent
(6) Export Merchant
(7) Buyers for Export
    (a) Resident buying offices
    (b) Foreign government purchasing missions
(8) Export and Import Brokers
(9) Cooperative Export Selling

Assuming the above has been accomplished, our American goods should meet the language, measurement and labeling requirements of the country in which they are to be sold. I hope the day is not too far away when we shall adopt the metric systems of weights and measurement. This would help exporters no end. Our foreign competitors are born with it and we suffer because we do not conform. Of course some manufacturers do, which only goes to prove my point that others should follow suit and be encouraged by our own Government to do so.

In analyzing the foreign market we need to follow rules of common sense. It matters not what the color or the language of a person is, because being a human being he has human desires just the same as any of the rest of us. Perhaps we have one very great advantage over most of our competitors in that our magazines carrying national advertising in such superior ways get to the most remote parts of the world and being graphic they create these reactions that I choose to call human desires. We must always keep in mind that basically our first sales are made as luxuries, most of them later becoming necessities. In this, foreign selling is no different from domestic selling. If anyone doubts this let him think of the automobile, to name just one item. Surely it was a luxury when we first bought it, but most certainly it is now a necessity, and so on ad infinitum.

In further analyzing the foreign markets, we must try to estimate purchasing power of the local currency. It is discouraging to try to sell American goods in a country that has a currency greatly depreciated by comparison to our own. To give you an idea of that, we are reading every day what the GI dollar is buying in the many lands where our troops are now occupying enemy territory or sojourning on allied territory.

It is silly to try to sell fur caps to the Filipinos, although I saw it done, but only once. It hurts all American business if one manufacturer sells something lower than the so-called American standard of living.

In the matter of labels we must meet the requirements of the buyers. Recently I saw a label being designed for a food item to be sold in China. Very great care was used **not** to print

J. F. Marias

the **wrong** colors. This delayed the printing until the proper colors could be approved, but it will pay dividends. I once saw an order of several thousand cans of fish refused because the picture of the fish gave the appearance that the fish was dead. That may sound silly until you learn that in that particular country, a tropical one, no one dared eat a dead fish. It has to be seen swimming in the sink, otherwise no eat. I once saw a large shipment of American cigarettes refused because of a very slight printing change. The manufacturer had decided to use the words "Made in the United States" as a substitute for

the former "Made in the USA." The natives noticed the change and concluded the new shipment was made in Japan. To those who could read no language, including their own, any change made them suspicious, and since they hated Japs, they refused to smoke this particular brand any more, although they were identical in every respect to their old favorites.

An export sale, generally speaking, is a surplus article. One would not sell anything as far as that goes if he needed it himself. Many, many good American firms will not get interested in export because they can sell all they can produce in the domestic market. You have heard that many times. But some more progressive producers see that by increasing their output and selling much of it abroad they are able to reduce the cost of manufacturing and therefore give to the domestic market a good item cheaper than if they manufactured only for the domestic trade. Nevertheless an export sale is a surplus sale, at least for the benefit of my picture as I want to give it to you here. All production, and especially farm production, is variable. All producers want to produce at least enough for their domestic market. Everything else becomes surplus in my present meaning. It seems to me that if a foreign market is developed to take this surplus off the hands of the producer the producer has a very great and important guarantee against heavy losses, and to that degree the price that he has to sell for in the foreign market, even though it be greatly lower than the domestic price, is not very important. The fact that he can sell it and keep it from becoming a surplus in his domestic market to break down his domestic price is something not to neglect.

I think that this is a good place to review the success of the Japanese in selling in foreign fields as our competitors. I make the bold statement that had it not been for our methods of production, selling and distributing, the Japs would not have been as high up the economic ladder as they otherwise would have been. Who ever heard of a Jap invention? What did the Japs ever initiate? Did you ever see anything in Japan that was not either an imitation of something that we or the Europeans first made or something very crude and quaint? But you certainly have seen many, many items like American flags and plastic Santa Clauses with the words "Made in Japan." Well, that's what I mean. Certainly the American flag is not of Japanese origin, nor is Santa Claus, but why was it that we bought so many of them? The answer is the same as the answer you will get in every part of the world. We Americans, more than any European people, made Japan what it was before the war, and incidentally we made it what it is today. That is also a demonstration of American initiative. I for one hope that we shall have the good sense to keep the Japs from imitating our items any more, any place. Remember that we first design, or invent, the item. Then we find a way to make it good and serviceable. Then we find a way to make it in large quantities. And then a way to get it into the hands of the people at a price they can afford to pay. And, finally, we find a way to get it into the hands of the foreign friends and thereby create business for us.

Pacific WORLD TRADE

Often we have the satisfaction of adding to the pleasure of living among the peoples of far away lands. All this is good, and the Jap recognized it, and so when he got things going, he found a way to make it cheaper and sell it to his benefit and we to a great degree lost considerable of our "follow up" market. It was not uncommon to have natives say, "Yes, that is a very fine article, but we must wait until the Japanese sell it to us cheaper." Nice people. But now the Jap is out of the way and so it appears that if we can get the economic balance back to something approaching a pre-war level, we should dig in for a long period of excellent foreign trade.

For those of you contemplating an entry into export trade at this time there is probably one big question, "How do I get export customers?" How you should get them and who they should be depends largely on what you have to sell. To determine the answers to these questions and several others which will have a direct bearing on your ultimate success as an exporter it is desirable to make an analysis of your market. The same rules of merchandising with minor variations apply to export selling as to domestic.

If a trip can't be made to study the market first-hand, there is a wealth of statistical data available here in this country for your perusal.

(1) Your local Chamber of Commerce has continuous inquiries from buyers abroad seeking certain U. S. goods.

(2) The Department of Commerce, Bureau of Foreign and Domestic Commerce, here in San Francisco under the able leadership of John Judge has a great amount of down-to-earth information which has been gathered and compiled by well qualified field representatives.

(3) The foreign department of your bank can give you information pertaining to credits, collections, rates of exchange, etc.

(4) Certain air lines and steamship companies have established bureaus to assist businessmen with their entry into the export field. They supply information on needs, customs, buying habits, freight rates, etc.

(5) A letter to the Commercial Attache at any of our embassies in the form of a definite inquiry will shed additional light on the problems at hand.

(6) Dun and Bradstreet's Foreign Division through their world-wide organization can supply complete credit information on any customer.

(7) One dollar will buy a complete report on any prospect from the World Trade Intelligence Division of the Department of Commerce in Washington.

(8) Many trade journals have foreign editions. If there is one of these in your field they will gladly supply you with information they have accumulated from experience with products and market conditions in their field.

(9) There are many reliable export houses who have years of experience in foreign marketing who have on their staffs individuals who are specialists in a particular field. No market survey should ignore the possibility of using the services of an export house as a possible distribution outlet.

Now you have the types of export outlets and information services on

(Continued on page 147)

New Policy Statement by Export-Import Bank

FOREWORD

The recent expansion of the lending authority of the Export-Import Bank under the terms of the Export-Import Bank Act of 1945 has accentuated the need for a comprehensive statement of its general policies. The following statement was prepared in the light of both the established practices of the Bank and the new problems of foreign-trade financing growing out of the transition from war to peace. The purpose of the statement is to provide the public with information on the facilities of the Bank and on the policies which guide its operations.

WAYNE C. TAYLOR,
President.

The Export-Import Bank was established in 1934 as a banking corporation organized under the laws of the District of Columbia. The Bank was continued as an agency of the United States by acts of Congress in 1935, 1937, 1939, and 1940 and was made a permanent independent agency of Government by the Export-Import Bank Act of 1945.

The purpose of the Export-Import Bank of Washington, as laid down by Congress, is to aid in "the financing and facilitating of exports and imports and the exchange of commodities between the United States or any of its Territories or insular possessions and any foreign country or the agencies or nationals thereof." All of the operations of the Bank are and must be related to this fundamental purpose.

Powers

The Export-Import Bank has been given broad powers to do a general banking business and to make practically any type of loan, without limitation as to the amount of loans to any one borrower, insofar as the exercise of these powers is necessary to carry out its fundamental purpose of assisting in the financing of United States foreign trade. (See later paragraphs for a statement of transactions expressly forbidden to the Bank or excluded by reason of its general policies.)

Sources of Funds

In addition to its capital stock of $1,000,000,000 subscribed by the United States, the Bank is authorized to borrow from the Secretary of the Treasury on the evidence of its

own debentures or other acceptable obligations an amount not in excess at any one time of two and one-half times its authorized capital stock. The earnings of the Bank provide an additional source of funds.

Limitations Imposed

The Bank shall not have outstanding at any one time loans and guaranties in an aggregate amount in excess of three and one-half times its authorized capital stock, or $3,500,000,000. However, over a period of time the Bank can obviously handle a total volume of business larger than this amount because of participations by private banks with the Export-Import Bank without its guaranty, because of sales by the Bank to private persons of paper from its portfolio without its endorsement or guaranty, and because of the release of funds through repayments.

Organization

The Export-Import Bank Act of 1945 places the management of the Bank in a Board of Directors consisting of the Foreign Economic Administrator as chairman (so long as the Foreign Economic Administration shall exist), the Secretary of State, and three full-time directors appointed by the President of the United States by and with the advice and consent of the Senate. Not more than three of the five members of the Board shall be members of any one political party. Participation by other Government agencies in shaping the policies of the Bank is provided through an Advisory Board consisting of the chairman (at present the Foreign Economic Administrator), the Secretaries of State, Treasury, and Commerce, and the Chairman of the Board of Governors of the Federal Reserve System.

The National Advisory Council created by the Bretton Woods Agreements Act has the same membership as the Advisory Board of the Export-Import Bank, except that its Chairman is the Secretary of the Treasury. It is responsible for coordinating the policies of the Export-Import Bank with those of the United States representatives on the Bretton Woods organizations and with all other agencies of the Government to the extent that they make foreign loans or engage in foreign financial transactions.

The close working relationships between the Bank and the Departments of State, Treasury, Commerce, Agriculture, and the Board of Governors of the Federal Reserve System, as the permanent agencies of Government primarily concerned with foreign economic operations, serve to keep them fully informed regarding individual loan projects under consideration by the Bank and give them full opportunity to call attention to any possible conflict between the day-to-day activities of the Bank and their activities in carrying out the international economic program of the United States. They have also facilitated access by the Bank to the information and technical services of these Departments and the Federal Reserve Board and in

OFF FOR CHINA!

One of ten N-3 coasters recently purchased by the Chinese Government and outfitted at Consolidated Steel and Kaiser Shipyards. They were due to carry cargoes of railroad ties, nails, hardware and a wide assortment of UNRRA materials. The vessels are to be used in coastal and river operations in China. Purchase was negotiated for China by Robert H. Chiang.

this way enabled the Bank to limit the size of its own technical staff.

The operations of the Bank are administered by its officers and staff under the general supervision of the Board of Directors.

Basic Principles

Since its organization in 1934, the Export-Import Bank has been guided in its lending operations by the following basic principles:

(a) In accordance with the statutes governing its activities, **the Bank makes only loans and guaranties which serve to promote the export and import trade of the United States.** The Bank promotes foreign trade directly by financing exports and imports as specific transactions and by financing exports in connection with development projects and programs in foreign countries. Loans of the latter type have a further indirect effect upon United States foreign trade; for they assist in building up the economies and raising the levels of income of foreign countries, which thereby become better markets for American products and better suppliers of imports to this country. Thus, the Export-Import Bank is guided in its lending policies by the demonstrated fact that the best trading partners of the United States are countries which have reached the highest state of economic development.

(b) In accordance with its established practice and as explicitly provided in the Export-Import Bank Act of 1945, **the Bank makes loans generally only for specific purposes.** A corollary of this principle is that disbursements under a commitment by the Bank are made only upon receipt of evidence satisfactory to the Bank that the purposes of the loan have been carried out by the borrower. Conversely, the Bank does not make lump-sum advances for use as the borrower sees fit.

(c) As a matter of prudent management and as required by law, **the Bank makes only loans which offer reasonable assurance of repayment.** The restriction of loans to specific purposes is an important means to this end, as is also the spread of maturities over the productive life of a project in order to facilitate repayment. Furthermore, all loan applications are carefully analyzed by the Bank's staff from the legal, engineering, and economic points of view and must be approved by its Board of Directors.

(d) As a general rule, **the Bank**

extends credit only to finance purchases of materials and equipment produced or manufactured in the United States and the technical services of American firms and individuals as distinguished from outlays for materials and labor in the borrowing country or purchases in third countries. The reasons for doing so are principally two: (1) The limited resources of the Bank should be used with rare exceptions solely for the purpose of directly financing and facilitating United States foreign trade; (2) foreign countries should not ordinarily assume external indebtedness to finance expenditures in local currency.

(c) In accordance with its own rule and the express instruction of Congress, **the Bank does not compete with private capital but rather supplements and encourages it.** The activities of the Bank are confined, therefore, to dealing with certain types of risks which private banks are not in a position to assume without Government assistance and with other risks which they are not prepared to assume at all.

The principle of non-competition with private lending institutions is further carried out by the readiness of the Export-Import Bank to sell paper which it has acquired and by arrangements under which the Export-Import Bank undertakes in advance to purchase from commercial banks notes arising out of specified transactions financed in the first instance by the commercial banks.

What the Bank Finances

The Export-Import Bank is prepared to assist, under proper conditions, in financing exports from the United States and imports into the United States of products of all kinds. It is also prepared to aid in the purchase of engineering and other technical services in the United States. As a matter of practice, however, its assistance is required primarily in facilitating exports of tangible commodities the sale of which involves extended terms of credit. Exports of commodities may be financed on the basis of values f. o. b. the inland point of shipment, f. o. b. the land port or seaport of exit from the United States, or c. i. f. a foreign port.

The Bank's financing of exports is of two general types. The first type consists of credits for the benefit of individual United States exporters to facilitate the sale abroad of specific materials or equipment. The second type consists of a line of credit in favor of a foreign government, a foreign bank, or a foreign firm, to be available during a stipulated period of time, for the purpose of facilitating the purchase in the United States of specific materials, equipment, and services. Although different in form, the two types of credits obviously serve a single purpose. It is often a matter of choice or convenience whether a given transaction or set of transactions is financed by extending credit to American exporters or by making a loan to a foreign country or purchaser. Thus, it is clearly preferable from the point of view of ease of administration to make an arrangement with a foreign government or purchaser rather than separate arrangements with each of several hundred United States suppliers who may be providing equipment for a given project. The difference between the two types of operations is made even smaller by the

fact that the guaranty of a foreign bank or government is usually required as a condition of credits extended on the application of individual United States exporters without recourse to them (i. e., credits involving no liability on the part of the exporter in the event of default by the foreign debtor).

What the Bank Does Not Do

There are a number of things which the Export-Import Bank is expressly prohibited from doing under existing law or which are excluded by its general policies. Thus,

(a) The Bank does not compete with private banks and does not, therefore, extend credits when private credit is available in adequate amounts and on reasonable terms.

(b) The Bank is prohibited by its charter from purchasing stock in any corporation. In other words, the Bank is not permitted to engage in equity financing.

(c) The Bank does not make lump-sum advances for use as the borrower sees fit.

(d) The Bank is not authorized by the language of the Export-Import Bank Act of 1945 to finance trade between the United States and its Territories or insular possessions. This means that the Bank may not assist in financing trade between continental United States and Puerto Rico, the Virgin Islands, Alaska, Hawaii, the Philippines, or other possessions in the Pacific or between any two of these Territories or possessions. However, the Bank may finance export or import transactions between United States Territories or possessions and foreign countries.

(e) The Bank does not ordinarily finance local currency expenditures.

(f) The Bank does not assume any obligation or responsibility for the issuance by any agency of the United States Government of any priority, allocation, permit, or license which may be required by law or regulation for the procurement and export of any commodity which it may finance. Nor does the Bank attempt to give advice to borrowers on possible suppliers of exports which it finances.

(g) The Bank does not undertake to select engineering or other technical firms or individuals whose services may be sought by foreign borrowers in connection with projects financed by the Bank, although it does require competent engineering and other technical direction of such projects and will finance long-term contracts providing for payments for engineering or other technical services.

Who May Apply for Credit

The facilities of the Export-Import Bank are open to United States exporters either of goods or of engineering and other technical services, to United States importers, and to foreign governments, the agencies of foreign governments, and foreign firms and individuals. In brief, the Bank's facilities are accessible to any one requiring assistance and to whom the granting of assistance will aid in the financing of United States foreign trade.

The Export-Import Bank Act of 1945 released the Export-Import Bank from the pre-existing prohibition against loans by the Bank to foreign governments in default on their obligations to the United States Government. The Act also permits any individual, partnership, corpora-

tion, or association to participate with the Export-Import Bank in any of its authorized transactions and thus sets aside, with respect to participations with the Bank, the provisions of the so-called Johnson Act prohibiting loans by private persons to such governments.

How to Apply

United States exporters, both of goods and of engineering and other technical services, or United States importers who wish to apply to the Bank for credit may do so by writing directly to the Export-Import Bank of Washington, Washington 25, D. C., or, preferably, by seeking assistance from the Bank through their own commercial banks. It is recommended that the applicant consult his bank in any case, since in most cases it will be familiar with the facilities of the Export-Import Bank and will be able to judge whether or not the assistance of the Export-Import Bank is necessary and appropriate. Banks may obtain further information with respect to Export-Import Bank policies and procedures from their local Federal Reserve Banks.

The following information is essential for the consideration by the Bank of applications from domestic exporters (and, with appropriate modifications, also for the consideration of applications from domestic importers):

(a) Description of commodity to be financed.

(b) Name of foreign country to which the exports to be financed are destined and the name of the foreign purchaser.

(c) Justification for seeking the assistance of the Export-Import Bank, including a statement of the credit terms to be extended to the purchaser and suitable evidence that neither the seller nor his bank is in a position to finance the transaction.

(d) Amount of credit desired and proposed terms of repayment.

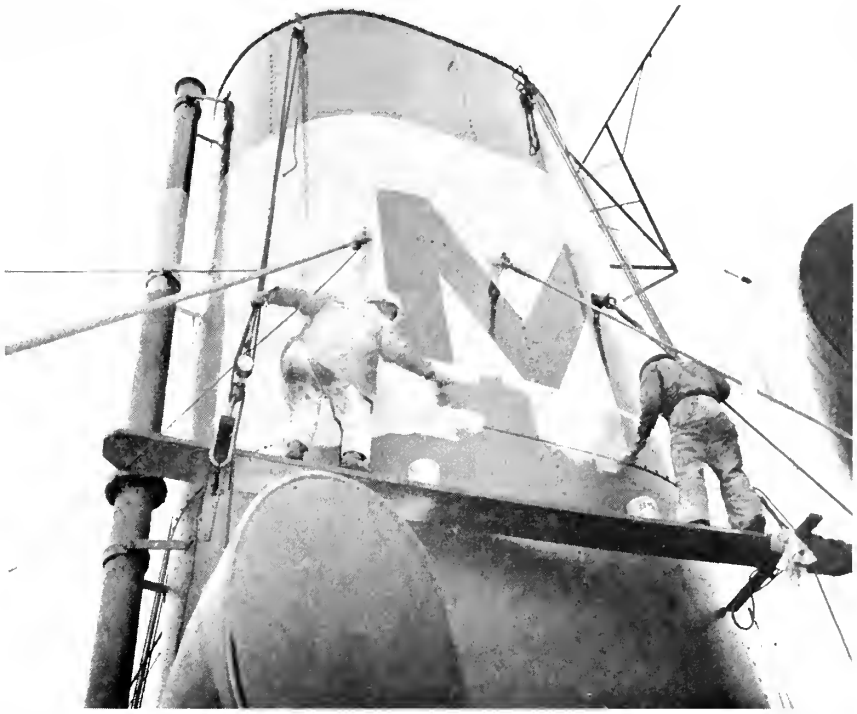
(e) Commercial bank and trade references.

(f) Comparative balance sheets and profit-and-loss figures for the preceding 3 years.

(g) In certain cases, cost sheets or other evidence of cost.

(h) Brief statement of history and experience.

GOOD NEWS!



Painting the Matson M on one of the Matson Navigation Company's liners. It is expected that 17 pre-war vessels will be restored to Matson control by mid-February.

(i) Credit information regarding the purchaser.

(j) Names of possible guarantors, together with an indication as to whether the guaranty of a foreign bank or government has been promised.

(k) Any other information which would be useful to the Bank in appraising the credit risk involved.

Authorized representatives of foreign governments may apply directly to the Export-Import Bank for credits or may initiate discussions through United States embassies and legations in their respective countries. In the consideration of applications from foreign governments or their agencies, the following information is necessary:

(a) Purposes for which the credit is to be used, including lists of materials, equipment, and services to be purchased in the United States and their suppliers (if known) and, when specific projects are involved, engineering and economic surveys.

(b) Justification for seeking the assistance of the Export-Import Bank, including satisfactory evidence that private credit is not available.

(c) Amount of credit desired and proposed terms of repayment.

(d) Statement of external assets of the country in the form of gold and foreign exchange, showing official holdings separately from private holdings and holdings of dollars separately from holdings of other currencies.

(e) Current and prospective rate of gold production.

(f) Statement of the international investment position of the country at long-term and short-term, including major commitments pending or contemplated, and an estimate of the amounts of interest and amortization due annually over the life of the loan on external fixed-service obligations.

(g) Summary of the record of the country as regards the payment of external debt and statement of the default status of outstanding external obligations.

(h) Analysis of the capacity of the country to repay on the basis of its current and prospective balance-of-payments position.

(i) Satisfactory assurances that dollars will be made available by the monetary authorities of the country to meet payments of interest and principal to the Export-Import Bank as they fall due.

Foreign applicants other than governments or their agencies may apply directly to the Bank, but the support of their governments will ordinarily be required before a credit can be negotiated. The information required of such applicants consists of items (a), (b), and (c) in the itemization applicable to foreign governments and items (e), (f), (h), (j), and

(k) in the itemization applicable to domestic firms or individuals.

Advance Commitments

United States exporters who desire to bid on foreign business may apply to the Export-Import Bank for credit with a view to securing commitments in principle in advance of the submission of bids. When more than one United States exporter is interested in obtaining a given order, the Bank will indicate identical or similar terms to all qualified bidders in order that the successful bidder, if a United States exporter, will be determined solely on the basis of price, quality, and proposed delivery schedule, rather than upon any advantage in credit terms created by the Bank.

The Bank does not look with favor upon requests for assistance from exporters who have not consulted it prior to making credit engagements to foreign buyers.

Nonrecourse Financing

The percentage of the credit risk involved in any export or import transaction which the Export-Import Bank will assume without recourse on the exporter or importer depends upon the circumstances in each case. Under present conditions, nonrecourse financing of exports by the Bank almost invariably requires the endorsement or unconditional guaranty of a foreign bank or foreign government.

Maturities

The maturities of credits granted by the Export-Import Bank are arranged in accordance with the circumstances in each case. Generally speaking, the financing of trade in consumption goods is limited to relatively short-term credits. On the other hand, the financing of trade in durable productive equipment may be on terms extending over a period of years. Where extended terms are involved, principal amounts are ordinarily made payable in equal installments beginning with the first or some subsequent interest date.

Interest Rates

The rate of interest charged by the Export-Import Bank depends upon the type of credit involved in each case, is computed on the outstanding balance, and is usually payable semiannually. The Bank is obliged to charge interest sufficient to cover the cost of its own funds, defray its administrative expenses, and accumulate a reasonable reserve against losses in order that the Bank may be self-sustaining. The Bank is also bound to consider market rates of interest in order to avoid what might be construed as competition on a rate basis with private sources of credit. Interest rates are uniform to all borrowers for any given type of credit.

Security

Loans to domestic exporters, importers, and manufacturers are usually made on the basis of the credit standing of the borrower, supplemented by the guaranty of a foreign bank or government in the case of loans made without recourse to the applicant. Credits to foreign governments and their agencies are made on the basis of the general credit of the country or agency, supplemented where desirable and appropriate by a pledge of specific revenues or specific receipts of dollar exchange. The Export-Import Bank attempts to arrange the terms and conditions of its loans in accordance with the circumstances in each case and with a view to creating the type of obligation which is most suitable from the point of view of both the borrower and the Bank.

Aid to Small Business

As a special aid to small and medium-sized firms engaged in exporting, the Export-Import Bank extends credit lines to individual firms which are experienced and of good repute, but which are hampered by lack of capital in obtaining adequate accommodations from private sources. These credits are revolving and are available for limited periods, generally from year to year, upon presentation for discount by the Bank through its agent bank of drafts on approved foreign purchasers. These credits are designed especially to help small firms increase their export commitments without the necessity of raising additional capital. Comparable facilities are available to small and medium-sized firms engaged in importing.

Vis-a-Vis Commercial Banks

It is a cardinal principle of the Bank's operations that it does not compete with private banks. This principle is carried into effect in a number of ways. As indicated above, the Export-Import Bank prefers to receive applications for loans from private firms and individuals through commercial banks to insure that private credit is not available. The Bank attempts to secure the maximum participation by private banks in credit arrangements to which it is a party. The Export-Import Bank commonly uses the facilities of commercial banks for making funds available to borrowers under lines of credit, receiving payments of interest and principal, and for handling other matters in connection with the extension and collection of credits. The Export-Import Bank enters into agreements with commercial banks under which it undertakes in advance to purchase from them notes arising out of specified transactions financed in the first instances by the commercial banks. It stands ready in turn to sell to commercial banks or other private investors paper from its own portfolio.

By using the services of commercial banks, and other private organizations to the fullest extent possible, the Export-Import Bank is able to keep its own operating personnel at a minimum.

Relation to International Bank

The Export-Import Bank will not compete in any sense with the proposed International Bank for Reconstruction and Development. This will obviously be true during the period before the International Bank comes into being. It is also true with respect to short-term and medium-term credits to United States exporters and importers, because this is a field in which the International Bank will not operate. With respect to long-term loans to foreign governments, the activities of the Export-Import Bank and the policies of the United States representatives on the International Bank will be coordinated by the National Advisory Council on International Monetary and Financial Problems, as provided in the Bretton Woods Agreements Act. The making of long-term loans to private foreign companies by the Export-Import Bank and the International Bank will be coordinated in the same way.

Marine Transportation

Public Resolution No. 17, Seventy-third Congress, requires that exports of agricultural or other products fostered by loans made by any instrumentality of the United States Government shall be carried exclusively in vessels of United States registry unless it is determined by proper authority after investigation that such vessels are not available in sufficient numbers, or in sufficient tonnage capacity, or on necessary sailing schedule, or at reasonable rates.

First 1946 session of San Francisco's Foreign Trade Association at the Fairmont Hotel. Left to right: T. Douglas MacMullen, Executive Editor, Pacific Marine Review; Charles Romanowitz, Yuba Manufacturing Co.; Hon. A. Sporon-Fiedler, Consul General of Denmark and dean of San Francisco Consular Corps; William L. Montgomery, president of the Association and managing director, China-America Council of Commerce and Industry; Baron James Baeyens, Consul General of France; Hon. Henry Beaujard, Commercial Counselor to the Consulate General of France; William F. Minehan, assistant vice president, Bank of America, and Chairman, Foreign Credit Chapter, Credit Managers' Association. Gazing south in the lower right-hand corner is George Davis of the Argentine Trade Promotion Corp.

"World Trade Preview"

at the Foreign Trade Association of San Francisco

In a meeting planned as a brief symposium to hear the thoughts of a few leaders as to what can be expected during the coming year in world trade developments, the Foreign Trade Association's new president, William L. Montgomery, inaugurated his official term with one of the most enthusiastic meetings since pre-war days. It was held January 7 at the Fairmont Hotel, San Francisco.

Mr. Montgomery, who is managing director of the China-America Council of Commerce and Industry, Inc., and long-time manager of the World Trade Department of the San Francisco Chamber of Commerce, enlarged upon opportunities and recent developments.

President Montgomery introducing Consul General Sporon-Fiedler.

Charles Romanowitz of the Yuba Manufacturing Co., chairman of the Bay Area Promotion Committee, outlined the plans for the Institute of World Trade, since held in the University of California Extension Division.

William F. Minehan, assistant vice president of the Bank of America and chairman of the Foreign Credit Chapter, Credit Managers Assn. of northern California, with traditional banker's conservatism quoted credit conditions in various foreign countries.

T. Douglas MacMullen, executive editor of Pacific Marine Review, reviewed conditions both favorable and unfavorable with which the industry in general is concerned. They ranged through port conditions, tariffs, markets, ships, planes and freight rates. His conclusion was that the markets are waiting and obstacles can be made stepping-stones by those who just dig in and **trade.**

William F. Minehan and Alvin E. Eichholz. Eichholz is manager, World Trade Department, S. F. Chamber of Commerce, and secretary of the Foreign Trade Association. If there is anything he didn't know about foreign credits, he will have learned it from Banker Minehan.

John A. Sowers

PROMOTED?

John A. Sowers, manager, World Trade Department, Oakland Chamber of Commerce, has announced his resignation effective February 1. Mr. Sowers, who is well known in trade circles on the Pacific Coast, has directed the Chamber's world trade activities since 1935 except for service during the war years with the War Production Board.

He will join the Los Angeles Chamber of Commerce as assistant manager of the World Trade Department and will be in charge of the Far Eastern Division. He has been identified with world trade activities in the Bay Area since 1931. In 1935 he joined the Oakland Chamber of Commerce as head of its World Trade Department, and in 1936 made a comprehensive tour of China, Japan, Korea, Manchuria and the Philippines, followed by a three-months' trip around South America in 1937. He has served the Oakland Foreign Trade and Harbor Club as president, vice president, secretary and director. He is a member of the Delta Phi Epsilon, national foreign service fraternity; Pan American Association; Bay Area Maritime Committee, and is secretary of the Bay Area World Trade Promotion Committee.

Mr. Sowers has been identified with international affairs since his graduation from George Washington University in 1926. For two years he attended the School of Foreign Service, Georgetown University, where he majored in international relations, marketing, money and banking, foreign exchange, international law, and export merchandising and procedures. Following his graduation he became associated as assistant export manager of a large hardware manufacturing concern.

In announcing his appointment, General Manager Harold W. Wright of the Los Angeles Chamber stated, "As one of the best-known organization executives in the international commerce field on the Pacific Coast, Sowers will have an opportunity for carrying out in Los Angeles on an expanded scale the successful trade promotion activities he has handled while with the Oakland Chamber of Commerce."

Pacific WORLD TRADE

Employment of Veterans In Foreign Trade

Listing the sources of information on what is needed to obtain employment in foreign trade and where and how employment may possibly be obtained, the National Chamber's Foreign Commerce Department has issued a three-page mimeographed circular entitled "Employment in Foreign Trade." Copies are available upon request. The circular points out:

A well-known foreign trade authority has stated that firms pick their employees on two bases: (a) because of their knowledge of the product and the industry; or (b) their knowledge of the foreign field.

Some companies think it is easier for a man to learn foreign trade practices than it is to learn the company's products and methods of doing business. In addition, a good personality suitable to foreign trade and ability to be quick to learn are needed to succeed in foreign trade.

Some companies will employ complete outsiders to the company who have a knowledge of exporting and other qualifications, while other firms will take a pretty careful look over their existing personnel. The domestic departments of companies are quite often a stepping stone to foreign trade.

New Chile-Argentine Tunnel Studied

By agreement of the governments of Argentina and Chile, a commission of engineers of both countries has been appointed to study plans for the construction of a 3-kilometer tunnel through the Andes, between Juncal, on the Chilean side, and "Las Vacas" on the Argentine side, according to the foreign press.

The tunnel is intended to form part of the Pan American Highway and will also be used by the Transandine Railway, it is said.

R. E. Waterlow Elected

At its recent annual election, the Export Managers' Association of San Francisco elected R. E. Waterlow as its new president for the year 1946. Mr. Waterlow recently joined the staff of Frazar & Hansen, international merchants, and is well known in foreign trade circles.

Other officers elected for the coming year are: L. A. Elsener, Chicago Bridge & Iron Co., vice president; Luis Yribarren, Crown Willamette Paper Co., secretary; David Mari, Fibreboard Products, Inc., treasurer.

This Association has played an important part in San Francisco's foreign trade life for many years and looks forward to 1946 as one of the most active and important years in foreign trade history.

R. E. Waterlow

Quotes from the International Bulletin of the World Trade Department, San Francisco Chamber of Commerce

Information on Far East

Local firms can obtain information on commercial conditions in the Far East more speedily by addressing inquiries to the San Francisco field office of the Department of Commerce or to the Bureau of Foreign and Domestic Commerce in Washington rather than to consulates in the Far East, according to the Department of Commerce.

Consulates in the Far East, reopened since the end of the war and still under-staffed, are not yet able to handle a large volume of commercial inquiries. In general, information desired by American firms is available in the United States in readily usable form, the Department pointed out.

Import License Requirements Lifted For China

China has been removed from Procedural Group A by the Office of International Trade, and remains, however, in Country Group K with all attendant general license privileges.

The effect of this new order is that when submitting export license applications covering shipments to China, exporters are not required to specify the Import Permit Number of the Chinese Importer. However, during the first quarter of 1946 the Department of Commerce will endeavor to give preferential consideration insofar as possible to those applications supported by import permits issued prior to the announcement.

Discontinuance of Philippine Registry Numbers

Discontinuance of the registry-number system established for controlling imports into the Philippine Islands was announced effective January 1, according to the Department of Commerce.

It has been explained that the conditions which made necessary the setting up of the system have sufficiently improved so that the procedure is no longer required.

Trade with Japan

Import and export trade between the United States and Japan will be handled by Government agencies for at least another six months. Exports to Japan will be procured through the War Department, Quartermaster General. Imports will be handled through the U. S. Commercial Company of RFC somewhat as it handles imports from Italy. It is understood that exports to Japan will consist chiefly of foodstuffs and products

needed for the maintenance of a minimum subsistence level for the country.

Bretton Woods Agreements

The International Monetary Fund, and the Bank for Reconstruction and Development were brought into being in Washington on December 27, 1945, when representatives of 28 nations signed documents indicating that their Governments had ratified the Bretton Woods Agreements and had deposited the initial payments towards the expenses of the organization. The Fund will have $8,800,000,000 in gold and currencies at the start, and the Bank initial subscriptions of $9,100,000,000.

CREATING EXPORT SALES

(Continued from page 139)

this end which should be considered in your survey.

Just as important a consideration as your outlet here is the proper channeling of your business in the country of sale.

Here are the types of organizations or outlets abroad which you must of necessity consider.

(1) Distributor
  (a) Exclusive
  (b) Non-exclusive
(2) Wholesaler or jobber
(3) Commission Agent
(4) Retailer
(5) Direct user or purchaser
(6) Broker
(7) Resident salesman
(8) Branch Office
(9) Foreign offices or agents of export merchant

Most of the factors to be taken into consideration in a foreign market survey are the same as would be considered in a domestic one. As we said before, pay particular attention to what may seem like minor details, such as labels, size and style of packaging. Instead of having competition from U. S. firms as we do here, remember that competition in a foreign country comes from three directions: (1) the national manufacturer, (2) firms from other countries and (3) last, but by no means least, many of the same old competitors you do battle with daily in Milwaukee or San Diego.

When you decide to enter the market after you have the results of your survey—go ahead with the same enthusiasm and ingenuity you would use on a domestic campaign.

Don't expect big returns immediately because you are now selling to the biggest mass market in the world without even going into the export business.

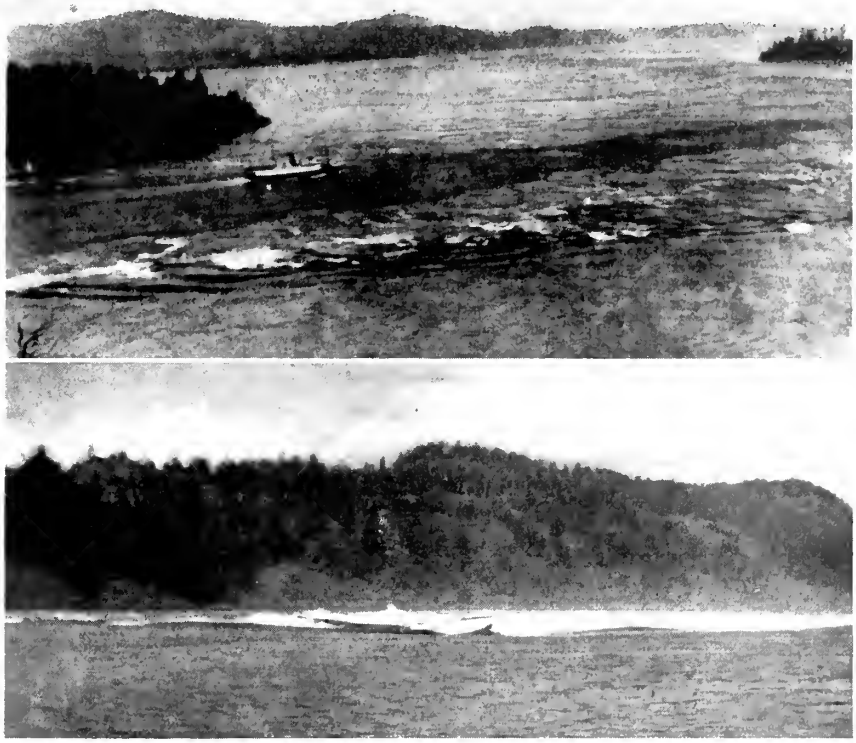
Don't think you know all the answers. Listen to the advice of your selling agents.

Always remember to play the game fair and square. A blow below the belt won't benefit you or anyone else in this country engaged in export business.

If you follow the rules of the game there is every reason to believe that you will get your share in a direct proportion to what you put into it.

Mariners' Dread, Ripple Rock, to be Blasted Out

By Francis Dickie



Top of page: S. S. Cardena, passenger ship of Union Steamship, Ltd., at engine speed of 12½ knots with tidal current near Ripple Rock is making 26 knots. Even the most powerful steamers cannot buck high flood tides, which in times of storm build up a current reaching speed of 18 knots. In the past 30 years, time lost by ships waiting for short periods of "slack" (quiet water) to run this dangerous tide race amounts to millions of hours. *(Photo courtesy Capt. J. Muir)*

Center: Flood tide begins in Seymour narrows near Ripple Rock. A seething, roaring, dreadful turmoil of white water, gigantic whirlpools, overfalls, eddies in a racing current with speed at times of 18 knots, defies passage of even a battleship. Ships go through on short periods of calm water, depending on time and state of tide.

Below: Flood tide in Seymour Narrows. *(Photos by Ronald Miller)*

SHIPS' CAPTAINS plying the North Pacific to and from Alaska, and all masters of coastwise shipping, will be jubilant and relieved to know that the Canadian Government's determination to destroy the nightmare of the North Pacific sea-lane, known as Ripple Rock, is undeterred.

Though the first attempt to drill the Rock from a barge held over it in the swift current, lasting nine months, from March to November, 1943, was a disastrous failure, costing half a million dollars, the Government's contractors, B. C. Bridge & Dredging Co., have now returned to the attack, aided by an additional grant of $125,000.

Ripple Rock is the worst menace on the "Inside Passage," which stretches along the coast of British Columbia, protected from the sweep of the open Pacific by islands, for nearly a thousand miles.

Of large passenger and freight steamers approximately 2000 per year pass the rock, shipping worth approximately $25,000,000, carrying 175,000 passengers, 2,000,000 tons of freight, cargo valued at $107,000,000.

The nautical description from the B. C. Pilot Vol. 1 reads, "Ripple Rock (Lat. 50° 08′ North. Long. 125° 21′ W). A dangerous shoal with two heads lying north and south of each other, nearly a cable apart, the northern head 1½ fathoms least water, being the shoalest, lies in the centre of the Narrows." How exceedingly treacherous is this passage is emphasized by Commander B. L. Johnson, R.N.R., in his sailing directions published in the Vancouver Pilotage Service. This officer has navigated ships for 30 years in these waters.

He writes: "Except to those with intimate local knowledge, it is recommended to enter the Narrows only at or near slack water . . . during the strength of either stream, the eddies are very heavy and extra men should be at the helm . . . on big tides, a

speed of sixteen knots and a vessel particularly quick to answer her helm is necessary for a safe passage during the second and third hours of the ebb. . . . Strangers are advised to navigate only at slack tide. . . . The passage should be used with caution at night, even by those having local intimate knowledge."

The loss of ships and cargo caused by Ripple Rock and adjacent water has run into many millions of dollars. Among vessels lost are:

1875—American Warship Saranac, total loss.

1875—American steamer Wachusett, total loss.

1884—H.M.S. Satellite (40 feet of false bottom torn off by R.R.)

On dates uncertain, presumed total loss, S.S. Amur, Spokane and Queen.

Of ships of American, British and Canadian registry which suffered damage varying from $1000 to $500,000 in more recent years were:

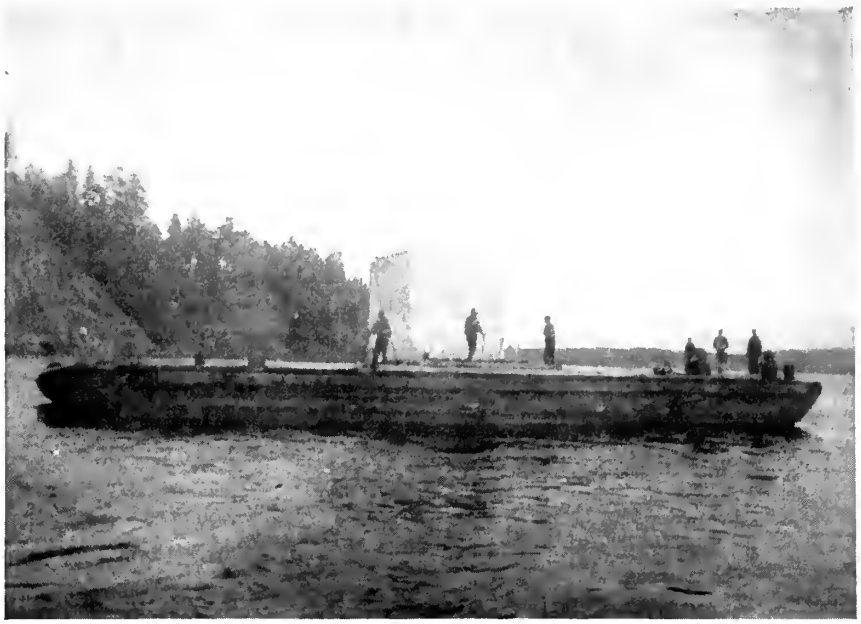
1902—S.S. Bonita.
1904—Danube.
1906—Themis.
1916—Princess Maquinna.
1919—Princess Ena.
1920—Prince George.

1929—Greylock; Aleutian (large passenger list, ship and passengers narrowly escaped complete wreck); Princess Mary.

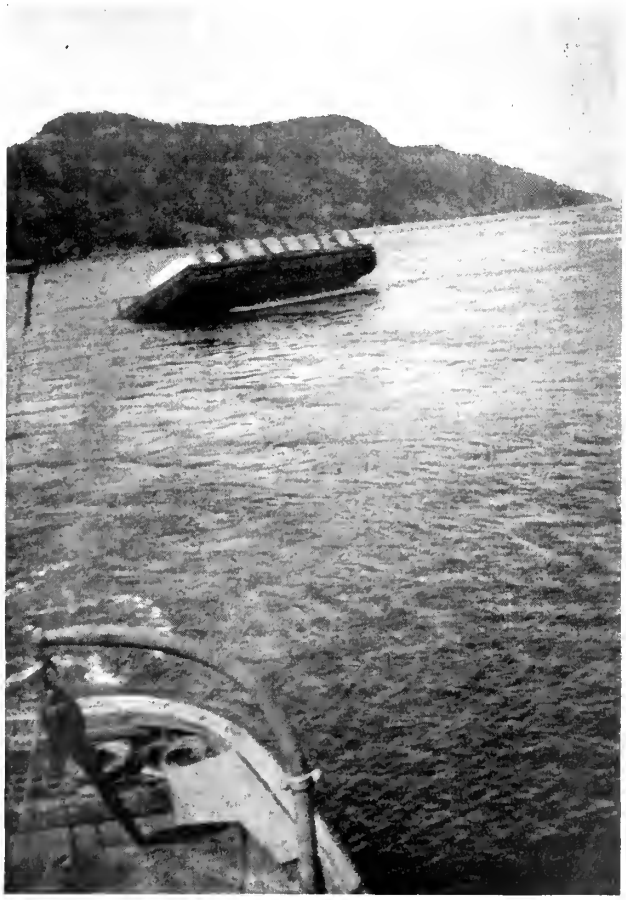
1944—William J. Stewart; Lakima (the latter with large passenger list saved from Rock only by heroic efforts of a small power boat keeping her in eddy to pass the Rock).

In addition, large numbers of barges, oil tankers, tugs, fishing boats and pleasure launches of which no records are available. The toll of lives taken in rowboats is also considerable.

But Ripple Rock's supreme triumph came on June 11, 1944. The Canadian Government's own Hydrographic Survey Ship, William J. Stewart, dedicated to pointing out to others dangerous places, a vessel equipped with hundreds of thousands of dollars worth of delicate nautical instruments, a vessel officered by men highly experienced in avoiding danger, this ship struck on Ripple Rock. Complete wreck was barely averted by beaching the Stewart. The over-all damage to ship and instruments was estimated at half a million dollars. It should, however, be most particularly noted that the officers were blameless. No man is master of the incalculable currents around Ripple Rock. The vessel going north in the Seymour Narrows met a southbound Union steamer, necessitating both vessels to deflect from course. This was just enough, in the Stewart's case, to throw her into one



Setting anchor (first stage). The 25-ton cement anchors for holding drilling scow in tide-race were built in quiet water on scows with special water compartments. Picture shows scow on level keel ready to drop anchor in required position at bottom of dangerous Seymour Narrows tide-race. *(Photo by Ronald Müller)*



Setting anchor (second stage). Compartment on scow opens, letting in water to tilt the scow till 75-ton anchor slides into sea.
(Photo by Ronald Miller)

Huge drilling scow, a little city in itself, shown with tugs in moment of quiet water in one of the world's swiftest tide races. A new anchor is being dropped, weighing 75 tons. Six anchors, totaling 550 tons, held it only temporarily as 11 steel cables kept breaking through "fatigue" caused by movement of scow in shifting water.

of the resistless currents driving the craft straight upon the Rock.

For 75 years this menace has been protected for the most fantastic of reasons: **as an "absolutely required pier-foot" for a bridge, one bridge in a proposed island-hopping scheme to connect Vancouver Island with the North American mainland.** At first, 75 years ago and for some time after, the Rock was to be a pier-foot for the bridge of a transcontinental railway, linking Montreal and Victoria. When three transcontinental railways were built and each ignored this bridge the protectors group changed their plea to a vehicular bridge. In 1943 this opposition gave way before the louder clamor of mariners and shipping companies for the Rock's removal.

In 1930 the Canadian Merchant Service Guild Inc., representing 90 per cent of the masters and mates engaged in coastwise shipping—The Vancouver Merchants Exchange; Vancouver Board of Trade; Victoria Chamber of Commerce; the B. C. Coast Steamships; the C.P.R.; Canadian National and Union Steamship Companies; the Shipping Federation; the National Association of Marine Engineers; the United Fishermen; the United States Navy; and shipping interests in Puget Sound, Columbia River, and California ports—brought their combined pressure to bear on the Canadian Federal Government.

The Government appointed a commission, which, on February 20, 1931, reported the removal of the Rock was desirable. It estimated the cost at $200,000. But nothing happened.

Not until 1942 did the Government's Department of Public Works at last yield to pressure. It first considered the possibility of bombing out the Rock from a plane. On the advice of Professor Webster, British expert on bombing, this idea was deemed not feasible.

Many mariners and mining engineers agree that the only practical manner to remove Ripple Rock is by regular mining methods of putting down a shaft on the shoreline of Vancouver Island and tunneling under the Rock, then crosscut it and blast the entire Rock at once. They point out that a similar tunnel was driven under the First Narrows at Vancouver to bring the city its water supply.

The West Coast Salvage and Contracting Company, in the beginning of 1943, submitted to the Government a plan to place a steel caisson over the Rock. Fill the caisson with concrete as a working base. When this was set, drill through concrete and Rock to the desired depth and blow the caisson and the Rock. The Government rejected this plan.

The feasibility of drilling the Rock from a barge anchored over it in this terribly swift stream was made the object of an experiment begun in June, 1942. This took the form of building a model Rock, tide-race and barge at the University of Washington, with a stream pumped from the nearby lake to simulate the tide-race. The experiment cost $5000 and **proved highly satisfactory.**

On May 26, 1942, W. G. McKenzie, president of the B. C. Bridge and Dredging Company, to which the Government had given the contract on a cost-plus fee basis, optimistically stated: "the entire top of the Rock, which has 19 pinnacles, will be blasted by 354 seven and a half inch holes. The estimated cost will be $375,000 and the work will be done in ten months."

After much preliminary examination and delay, the method of attacking the Rock was decided upon as a drilling from a barge over the Rock. In the spring of 1943 a specially constructed drilling barge, costing $160,000, was towed to quiet water in the vicinity of the Rock. It was a veritable small floating town. On it was mounted an 80-foot drill tower. It carried two 12 x 14 Washington donkey engines to handle the enormous anchoring cables of steel line. At the same time six concrete anchors were built on specially equipped scows.

The four concrete anchors to hold the corners of the raft to lie at right angles to the swift stream were 10 x 10 x 10 feet, each weighing 75 tons. The other two anchors to hold either end of the barge north and south, the lines of which were parallel with the flow of the stream, were 10 x 10 x 26 feet, each weighing 125 tons. To the four lighter anchors were affixed 1¼ inch steel cable; to the other two, cables of 1½ inch steel. The scows with the anchors were towed to the required position about the Rock. The water compartments on the scows were then opened. The water filling them tipped the scow until the concrete anchor slid into the water. The other end of the cables was attached to large buoys. When all anchors were set, the drilling barge was towed into position and the donkey engines took the lines from the buoys and drew these fast onto the drilling barge.

Then down the narrow channel shot the stream of the Narrows with all the force of the outer Pacific. The water came roaring, churning, twisting with incredible speed and varying currents. Under its ceaseless pressure the mighty steel cables were so whipped and vibrated by the leaping, swaying, enormous drilling barge that in the first 24 hours one of the starboard cables, at right angles to the stream, snapped like a thread in the hands of an impatient housewife.

Only by a swift maneuver of the attending tugs was the great barge saved from disaster.

Within two weeks another cable went. New anchors were made. The attempt at drilling was continued upon this great barge, while most of the time the mighty frame quivered, vibrated, as it leaped and swayed and clumped down upon the stormy water, held like an eternally agitated

chip in the grip of the tide-race. Amazing as it seems that men could stand such strain, the majority of the crew, working in this fantastic watery dance with death, stuck it out.

Indeed, before work ever began on this method of drilling from the water, the Chief Engineer of the Department of Public Works said of this attempt, unique in engineering efforts: "Drilling the Rock from a barge held in the stream is probably the most hazardous ever contemplated in the world."

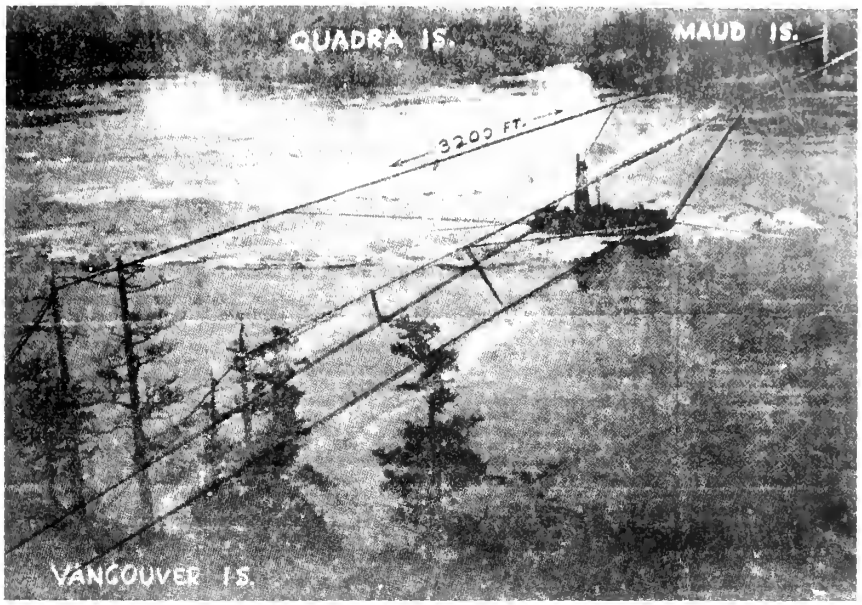
Little did he dream when he made that statement how right he was. By the time the autumnal storms were nearing the attempt was given up as futile. Eleven anchors had been lost in five months, and many fathoms of steel cable. Of the 354 holes the president had so proudly announced would be drilled in ten months, only eleven had been blasted. And of the half million dollars allotted by the Government to do the work not a cent was left.

From November, 1943, until the spring of 1945 work ceased on the project. Then, with an additional grant from the Canadian Government of $125,000, the attack was recommenced.

Despite the failure of the first drilling from the water method, and the criticism of its continuance by many mariners and all mining men, the second method now in progress very similarly parallels the basic idea of the earlier method, though this so signally failed.

The second method persists in drilling from a barge held over the Rock in this terrifically powerful and swift stream. The only difference is in the method of anchoring the drilling barge. Instead of anchors being sent to the bottom of the channel the barge is now held from two overhead cables.

High on the rocky cliff of Vancouver Island, "spartrees," such as used in "sky-line" logging methods, were raised. On Maud Islet, near the opposite (eastern) shore, similar "spar-trees" were placed. Extending from these across the channel, cables of 1¾ inch steel span a distance of 3200 feet. From these two lines of cross-channel cables extend downward "quarter-lines" to the drilling barge, a line to each of the four corners of the barge, and a line to either end. An additional help, two more lines



Constructed picture shows operation of new method to drill Ripple Rock. Scow is held over sunken rock by two overhead cables 325 feet above water to give clear steamer lane. Steel cables are 1¾ inches thick, 3200 feet long, secured to spar trees on either side of channel. From Vancouver Island side to scow, on closed channel side, are two additional cables at water level to scow. From overhead cables to scow, and to two lines at water level, descend "quarter-lines." In actual operation there is sag in overhead cables, but owing to number of lines shown in sketch, all are drawn straight for greater clarity.

extend from the "closed-channel" Vancouver Island side to the barge at water level.

With the completion of the raising of the "spar-trees" on either side of Seymour Narrows, at the end of June, 1945, the great steel ropes were brought into place to hold the barge in the second method of drilling Ripple Rock, a method unique in engineering annals, attempted here for the first time anywhere in the world.

On July 18 and 20, the Narrows were closed to navigation for several hours. During this time the two enormous steel cables, each weighing 11 tons, with a breaking test strength of 145 tons, were floated across the channel on 30 two-drum floats, with the cooperation of the Canadian Army Signal Corps and five tugs. These monsters of steel rope, specially constructed for the work by Wright's Canadian Ropes Limited, are the longest ever used in an operation carrying so tremendous a pulling load.

And so, with this unique method holding the drilling barge in the fast tide-race, drilling recommended in August, 1945, and continued until the end of September. But very little progress in the ultimate destruction of the Rock was achieved when work shut down again with the coming of the winter storm season in October.

(Continued on Adv. page 68)

Courageous drilling crew for 7 months rode on floating earthquake of drilling scow leaping about in one of world's fiercest tide-races.

Your Problems Answered

by "The Chief"

"The Chief's" department welcomes questions—Just write "The Chief," Pacific Marine Review, 500 Sansome Street, San Francisco 11, California

A Letter From A Victory Electrician

AMERICAN RED CROSS

Yokohama, Japan, December 1st, 1945.

Mr. John M. Dodds,
Field Engineer,
Pac. Dist. Eng. Div.,
General Electric Co.,
Russ Building,
San Francisco, Calif.

Dear Mr. Dodds:-

Inasmuch as we have already met I don't think it necessary to introduce myself. Right after I left your office last September I went down and signed up on this ship, the SS Plattsburg Victory, operated by the Coastwise Pacific Far East Lines, as electrician. This ship, incidentally, was one of the last, if not the last, of the Victory ships out of Yard 2, Richmond. In fact it was outfitted and commissioned so fast they sent her out minus electrical gear for the lifeboats for one of many omissions. This does not alleviate things during the lifeboat drills as those units have a way to turn laboriously. Another omission is the providing of an instruction book for the winches, anchor windlass, capstan, and generators. The winch gear is all GE, but the generators are Wesinghouse; one a 258E and the other a 240E which are running in parallel.

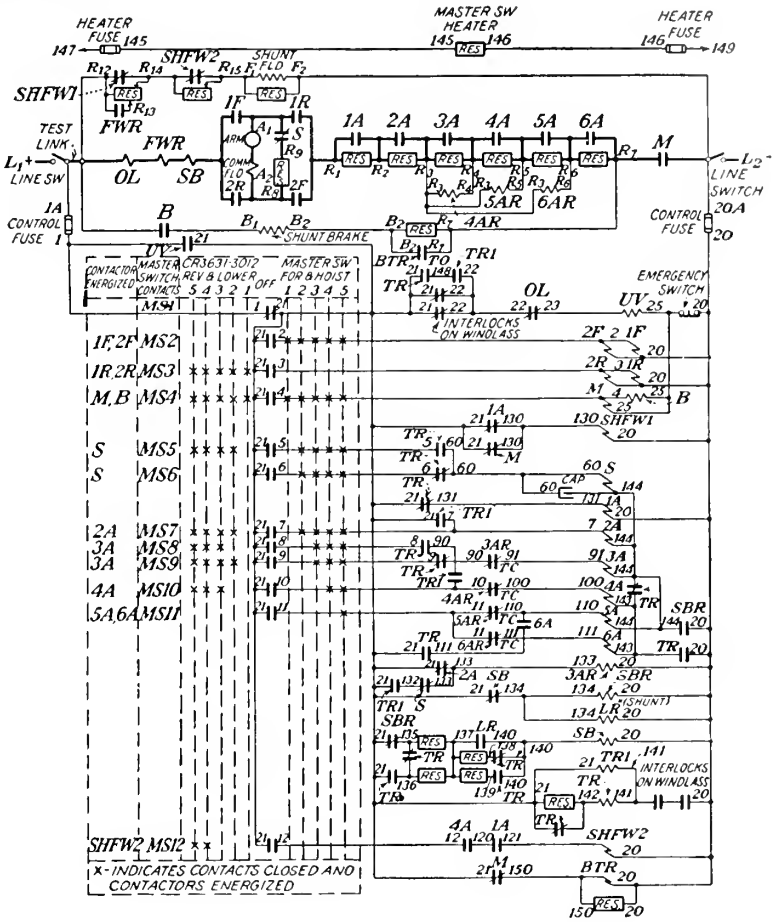
We sailed out of San Francisco on October 10, passing Halsey's fleet bound for the States the second night out. After being out about a week bound for Nagasaki, Japan, with a cargo of priority freight we ran head-on into a violent storm. The hatch cover over our forecastle deck was bashed in by the sea, as well as gear on the deck. Water poured into the forecastle compartments until it flowed over the hatch collars. Stored in one of the compartments was almost a thousand gallons of paint, several hundred gallons of fish oil, barrels of soap, coils of calking material, and black oil. As the ship was rolling to describe up to 42 deg. angles all of this freight was bobbed around in the seawater that had inundated the chain-locker, and resistor room, wherein is located the control panel for the anchor-windless, and its complement of 19 boxes of coil resistors.

All of the resistance was telescoped by being rammed against the skin of the ship and this content of course mixed together with each other using seawater to thin it down to a consistency of, let us say, a gallon of glyptal thinner to ½ gallon of glyptal. Just right for a spray-gun

were we looking for something to spray the resistors to give them an ohm reading to ground which they read after we tested them later. This all of course put a homogeneous sheet and ground across all elements of the board and the resistors. The overhead lighting cables, of course, were ripped from their studs and formed up like spaghetti in this great bowl of gray soup (the paint was 1000 gallons of gray color). Nothing was done about pumping for a couple of days as we all were busy serving the rest of the ship. We were forced to turn back to put the typhoon winds at our stern, and that stern bobbed up and down like the valve rod in an old coil-less engine.

Our bow was taking the sea to the mizzen mast awash. But we finally ran out of the storm and rigged up pumps, and in a few days we had all pumped out to a depth of 3 ft. of the settlings. These were siphoned out and bucketed out until all was dry except about 1½" of goo clinging to the bulkheads and to the entire anchor windlass. First we got busy on the degaussing cable as we were running into dangerous waters. We cleaned it off as best we could, took a megger reading, and shot a few amps. in her.

Coming into Japanese water we took the only set we had and socked 75 amps. to her expecting anything. But it held. We took later megger readings and found it was drying out nicely. While this was going on we skimmed the goo from the anchor windlass panel and resistors and found some of the resistors broken from floating cans ramming them and the wiring on the board pulled out in many places. The whole set-up looked like 2 mounds of soft clay, and would have been an effigy of the Bunker Hill monument to us if we didn't know electrons were flowing beneath those mounds of churned up paint, fish oil, etc., with a liberal garnish of ground up calking and packing protruding from them everywhere. But did we give up? No, sir, we went back and read Kipling's "If" from the Sailor's Manual of Inspiration, then retraced our steps over the catwalk and first skimmed the goo with our hands, then with a paint brush and kerosene, throwing everything in a basket if it felt like it came from GE before it was cemented and baptized in this strange country and manner, somewhere west of the International Date Line.



This is one of the connection diagrams used by Garrett.

Yes, Mr. Dodds, we took turns as the air was cold and incidentally the coffee in the galley was—Chase & Sanborn's. As in all things there is an ending; came the day we had things so we could see the outline of the 21 coils and the 14 resistors on the board. From there in it was tough. When the sailors cleaned the bulkheads they rubbed most of the diagrams of connections off that were pasted on them. We disassembled the whole board from top to bottom so that nothing but the slate remained. We disassembled all of the relays, the resistors, the master and limit switches, and gave them over to the wipers to clean. The relay coils we turned in to the War Shipping Administration for drying out, etc. This, of course, after we landed here in Yokohama.

Then I went around to a dozen ships before I had enough material to start rewiring. I bummed an instruction book from the last ship and I copied Drg. P-8299190, and the data on the relays, etc. It took me 3 days on that job alone, as I had to get that book back before they sailed. We took out the whole 19 box resistors and had one heck of a time getting the goo out of the spirals. Then we commenced on the main cables and meggered each out and retagged a lot of them. Then we reassembled the master switch and the limit switches and got in the motor, the gaskets of which over the commutator as those in the limit switches had allowed some water to come in. We literally cleaned that motor in carbon tetrachloride, but we succeeded in getting .5 meg-ohms and cleaned the salt-crystals off the segments to get a clear commutator.

By this time the coils came back from the War Shipping Administration and we compared them with one of each we had which were new. All were O.K. as far as ohms across were concerned, but the tubing to the pole pieces meggered low, so we dipped them all in Glyptal and let that dry while in the pole piece. The insulation on the reverse and forward blowouts was all shot so we wound scotch

THE SEXTANT

CHAPTER I (Continued)

(Note: In reading this installment on the sextant it will be well to refer to Figs. 1 and 2 in the preceding installment).

(5) **The Index Arm** is really a movable arm being free to rotate on a central axis under the index mirror, around a point on the frame which is the center of a circle of which the arc is a section. It is mounted on a round baseplate beneath the index mirror, which is firmly fixed to it at the top of the arm; while the bottom of the index arm (with the vernier attached) slides along the arc on the limb when pushed by hand.

(6) **The Index Mirror** is a reflector or mirror set in a brass frame perpendicular to the plane of the instrument. It is rigidly fixed to the index arm at its pivoting point in such a manner that its plane is over the center of motion of the index. The index mirror, being fixed to the index arm, moves with it and changes its direction as the direction of the index arm is changed. The glass is silvered all over, and is designed to reflect the image of the sun (or any other object) upon the horizon glass, from where it is reflected to the eye of the observer. It is fitted with a small, capped adjusting screw at its back.

(7) **Index Shades** of colored glass (usually four) of different densities are fitted to be turned down as required between the index and the horizon glass in order to moderate the brightness of the reflected image of the object—as the sun or moon.

(8) **The Index** is the arrow or zero on the index arm, which in the case of the vernier sextant is actually situated at 0′ on the vernier. In micrometer sextants, however, it is situated in the center of the blank space hitherto occupied by the vernier.

(9) **The Clamp or Clamping Screw.** When the index of the Sextant has been moved approximately to the correct angle, it must be brought into firm contact with the arc by being fastened at the back of the arc by a clamp or clamping screw. In the case of the endless tangent and micrometer sextants this clamping is automatic.

(10) **The Tangent Screw.** Attached at right angles to the index arm is the tangent screw, which comes into operation only when the index arm has first been clamped. It is really a "slow motion" screw, and by turning it the index arm is carried backwards or forwards along the arc. This enables the observer to make the images of the object come precisely in contact because, by its use, the index may be moved with far greater regularity than could be done by hand.

(11) **The Vernier.** The lower end of the index arm has a dividing scale cut on it (and therefore moving with it), which slides along close to the arc—called the vernier. This simply divides the arc cuts into 10 major divisions, each representing one minute of arc, and enables the reading of the index on the arc to be made with accuracy. In the ordinary sextant the vernier simply subdivides the 10′ intervals on the arc into 10″ intervals by each minute of arc being subdivided into six divisions of 10″ each.

(12) **The Microscope.** This is simply a magnifier fitted to all vernier sextants so that the divisions of the arc and the vernier may be more easily read. It is fitted on a movable arm on the index arm, and may be swung to cover the whole length of the vernier.

(13) **The Telescope.** By enlarging the object observed the telescope makes accurate observations easier. Also by the place of the image in field of the telescope it is easy to see whether the sextant is held in the proper plane for observation. Various telescopes are a part of the equipment of every sextant.

(14) **The Telescope Collar.** The telescope collar is provided so that the telescope may be screwed into it and thus kept rigidly in the correct position. It is really a double brass ring fitted inside the collar and is so constructed as to furnish means of adjusting the line of sight of the telescope parallel to the plane of the instrument. It is fixed to a stem in a direction perpendicular to the plane of the instrument, which in some sextants is just pushed into a socket and kept in position by a thumb screw, and in others it is screwed into the rising piece but is removable at will. It is "shipped" (i.e. screwed) into the collar by a continuous thread, or, as in most modern sextants, by an interrupted thread for rapidity of use.

(15) **The Rising Piece.** This is a device by which the telescope in its collar may be raised or lowered so as to give more or less light to the direct image, thus equalizing the illumination of the reflected and direct objects. It is usually operated by a milled head screw underneath the frame; however in some sextants it simply slides in a socket and is secured by a small thumb screw. The normal position of the telescope is where equal parts of the plain and silvered parts of the horizon glass are visible, but by raising or lowering the rising piece the telescope in its collar can be directed to either the silvered

Fig. 3: A "diamond frame" micrometer sextant stowed in its case. Note the position of the index bar (about halfway along the arc) and the erect telescope shipped in position.

or plain glass portions of the horizon glass, and the brilliance of the reflected image be regulated. As the telescope is raised less of the silvered part of the horizon glass appears in the field of view and the reflected image will not be so bright. If the telescope is lowered the brilliance of the reflected image will be greatest.

Figure 3 illustrates the manner in which a modern sextant is stowed in its case.

(To be continued)

Your Problems Answered

(Continued from page 153)

tape and some thin paper on the short bars that the coils covered and treated them with glyptal also. The same with the overload relay.

The air circuit breaker, as well as the XY and brake resistors we had to renew as the salt water, etc., had eaten through, and shorted the turns. The 19 resistor bank we reassembled. We treated the jumpers from the board to this bank with glyptal. Then we assembled the board itself. Actually we wore out the copy of the print which I had made before we were finished so guessed a little bit in the end. Then we pulled out #12, shot in the juice and after a few changes got a few clicks. After long arduous experiment we got the sequence in order. Then we switched the windlass to warping and started it up. Oh! what fun! The goo left on the 19 bank resistor began to fry and for a half hour we let it. Then there was enough smoke to use for a Pomona orange orchard smudge. But no go on the motor. So once again. Finally we found the trouble. We had shunted out the motor by connecting the jumpers wrong. Then we got the motor started. All O.K. both directions. Then we tried the hook. All O.K. there also.

So now we are ready to go. In a couple of days we will be loaded so we didn't lose any time at that. From here we go to Manila, P. I., and to Singapore, then Calcutta, India.

Besides this trouble several of the winches had faulty gaskets, but we saved them all without having to take out the armature. Let it be known here, Mr. Dodds, I gathered quite a bit of information for this job from your Vol. 3—Marine Electrician's Library called, "Power Uses in Marine Service," and will tackle a tedious synchronizing job in the engine room next.

As anything is liable to happen in such a room as this being without an instruction book on the generator is distinctly a disadvantage, I wonder if you couldn't arrange to have one sent to me. We receive mail regularly so will receive it if you will drop it in any mail box. The book I need is GEI-18208. I certainly would appreciate it. Much blood would have been saved on this job if I had had it to go by throughout the job, for you know how it is when you copy anything. My address is:

B. R. GARRETT,
c/o Postmaster,
San Francisco, Calif.
Coastwise Pacific Far East Lines,
SS PLATTSBURG VICTORY

Wishing you a Merry Christmas and a Happy New Year from this land of yen (now 15 for $1),

I remain, yours truly,
B. R. GARRETT.

THE CHIEF TO BRUCE

Dear Bruce:

Of course you will get the instruction book. It is being put in the mail at once.

It is just such a valiant struggle against odds as illustrated by your job that makes the American Merchant Marine crew the outstanding of the world. It also illustrates why the American worker is able to out-produce the world in goods. More power to B. R. Garrett and all the other ships' electricians.

Deck-Edge Elevators

In the closing months of the fight with Japan the Navy did many things "not in the book." Big carrier fleets were brought closer to Japanese-held land bases than had been considered possible—and got away with it. One thing that contributed mightily to this is the ability of a big carrier of the Essex class to get its planes up into the air quickly. In this the elevator system for shuttling planes between hangar and flight deck is a key factor. The dispatch and landing of planes from an aircraft carrier must be performed with almost split-second timing of crews, pilots, and the ship itself. A few wasted seconds may cost the lives of pilots, the loss of planes, even possible damage to the carrier or jeopardy to the mission.

On the older type carriers, each time the midship elevator carrying airplanes left the flight deck for the hangars below, a large hole appeared in the middle of the flight deck. During this time planes can neither take-off nor land, which clearly could be a serious matter. Furthermore, there was always the possibility that the elevator may be so badly damaged while in the downward position that it could not return to the flight deck, making the runway unusable. An elevator near the middle of the ship is absolutely essential to facilitate hangar operation as well as for strategic reasons. The Navy was posed with the problem of transporting airplanes between hangar and flight deck without creating a gaping hole in the landing and take-off area.

The solution devised by Westinghouse was to hang the elevator over the side of the ship—in short, a deck-edge elevator. Several factors greatly complicated this problem. A platform 60 feet long by 34 feet wide, an area on which a thousand people could stand and capable of lifting an 18,000-pound load, must be overhung from the side of the ship with no chance for counterweighting, and operated by a driving mechanism within the ship. Furthermore, the platform and supporting structure must be collapsible against the side of the ship when not in service and to enable the ship to pass through the Panama Canal. In heavy seas the ship may roll to such an extent that the platform and supports are submerged. When this happens, with the carrier knifing through the water at high speed, the structure is smacked

NEW EQUIPMENT AND MACHINERY FOR YARD, SHIP AND DOCK

Instruments Tested on Sperry's "Floating Laboratory"

Radar devices still on the secret list, as well as new developments in other marine instruments designed to increase safety in navigation, are now being tested by the Sperry Gyroscope Company in a well-equipped "floating laboratory." The precision instrument concern, makers of the famous gyro compass used aboard ships on seas around the world, has procured, under charter, use of the seagoing diesel-driven yacht Wanderer, so that new marine devices developed by Sperry research engineers can be rigidly tested under actual sea conditions.

Before the war it was comparatively easy to find a ship operator who welcomed the opportunity to have new navigating devices installed on his ship for service testing. The Wanderer, when under the private ownership of R. W. Allen, served to test a variety of Sperry equipment, and was fully equipped with such instruments as the gyro pilot, gyro compass, steering gear, and searchlight.

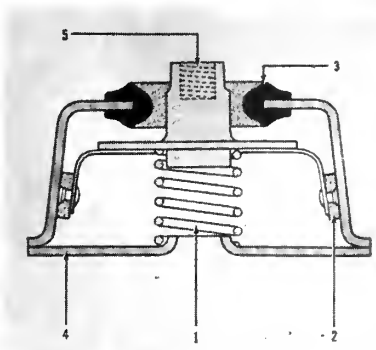
However, service testing on privately-owned vessels or yachts has become extremely difficult under conditions today because ships are not yet being operated over established routes. What may have been intended at sailing as a three- or four-day run today is likely to end in many months of wandering before returning to the home port. With the facilities of a marine laboratory, a practical necessity for Sperry, opportunity to procure use of the Wanderer offered the solution. A sturdy and seaworthy craft, she is 100 feet long, with a 26-foot beam, and draws 12 feet. She is powered with two diesels of 350 hp each, and with an auxiliary generator capacity of 120 kw for laboratory use. The cruising radius of 6000 miles provides adequate facilities for service testing under sea conditions. Her features, including an unusually large wheelhouse-chart room, complete cruising accommodations, machine shop, and ample space for equipment installation, make her well adapted for laboratory and experimental purposes.

Besides radar and Loran instruments, other equipment now undergoing tests on the Wanderer include Sperry's new gyro-magnetic compass, and latest developments in automatic pilots and steering apparatus.

Motor yacht Wanderer, in Coast Guard service during the war, is now Sperry's marine laboratory, serving as a proving ground for a host of new marine instruments, including radar and Loran.

●

Array of new navigation instruments seen in this photo are undergoing service tests on the "Floating Laboratory." These instruments include automatic steering apparatus, radar devices, and other equipment navigators dream about.



New Robinson Vibrashock Unit Mount

The unretouched photo (top) of an actual vibration test demonstrates the extremely high efficiency of the new Robinson Vibrashock unit mount in eliminating all vertical and lateral vibrations. Note that the model on the left is mounted on a conventional shear-type unit mount, that on the right on the newly developed Robinson Vibrashock unit mount. The conventionally-mounted model shows marked lateral and vertical vibration, while the Vibrashock unit mounts provide the other with virtually 100 per cent absorption of vibration in all directions. Similar tests carried out over a wide range of vibration frequencies showed the same Robinson superiority at all frequency ranges. Lower left: The Vibrashock unit mount is offered in three standardized sizes, ready to install for load requirements varying from 1/2 lb. to 45 lbs. Lower right: Cutaway view of typical Vibrashock unit mount shows: (1) Principal load-bearing stainless steel spring with three-way freedom of motion; (2) Built-in damping mechanism to kill low frequency oscillation and minimize resonance at critical frequencies; (3) Built-in three-way limiting snubbers furnishing a resilient stop to limit heavy load shocks; (4) Sturdy, light-weight metal housing, provided with standard attachment holes in its base; (5) A rugged load-carrying central stud tapped for standard machine screws.

New 633-hp, 7-Cylinder, Supercharged Diesel Engine

A new seven-cylinder, supercharged diesel engine is in production by the Buckeye Machine Company, Lima, Ohio, according to Robert L. Neiswander, sales manager of the company.

Buckeye has already shipped the first engine of a total of 26 which are scheduled for delivery to the United Nations Relief and Rehabilitation Administration to provide power plants for public utilities in war-devastated areas throughout the world.

The engine develops 633 hp at 600 rpm and produces 400 kwh of electrical power. Cylinder bore is 10½ inches, stroke 12 inches. The engine is 28 feet long, seven feet wide and nine feet high. It is complete with supercharger, generator, switchboard, starting tank and alarm system, which protects the engine from damage due to failure of cooling water of lubricating oil.

Navy Baffles Barnacles, Increases Range of Ships

A synthetic rubber hose reinforced with Fiberglas inner braid, through which hot plastic paint can be run at temperatures of 300° F., has been developed by the DeVilbiss Company engineers. This hose is now being supplied to the U. S. Navy and has the possibility of wide civilian application.

The Navy uses the hose to deliver the hot paint in a spraying operation on ships' hulls. The plastic paint forms a "skin" to minimize barnacle growth, a wartime development that increased the effective range of vessels in tropical waters. Composition of the plastic paint has not been revealed by the Navy.

This reinforcing for the hose was selected after tests of some two months because of its high tensile strength and heat-resisting qualities needed to withstand the operating pressures and temperatures encountered.

Hot plastic paint application on hulls doubles the time a ship can stay out of drydock before barnacle removal and still operate efficiently. It is now standard Navy practice to spray the hulls of vessels before they leave for missions in warm water areas. With spray painting equipment involving the use of this new hose, a crew of 140 men can apply the hot paint to an entire battleship hull in 16 hours.

The barnacle bugaboo has been a worry of shipping interests since the early days of sailing vessels. Marine investigation has shown that a 12-month accumulation of a 10,000-ton vessel may weigh as much as 30 tons, which fact is the basis of the maritime regulation that requires all ships to drydock once a year for hull cleaning and barnacle removal.

The new paint spraying hose, reinforced with two inner braids of neoprene-coated Fiberglas yarn, manufactured by Owens-Corning Fiberglas Corporation, has a minimum bursting pressure of 2,000 lbs. psi. Since the hot plastic paint is forced by compressed air through the hose at a pressure of 100 lbs., adequate margin of safety to the operator is allowed and deterioration of the rubber is minimized. The hose, one-half-inch inside diameter, will withstand maximum temperatures up to 400 degrees.

This 16-foot storage cylinder will house a height finder.

"Canning" Precision Instruments

There's going to be no more war—this has been demonstrated conclusively by editorial and feature writers, newspapers and magazines, and the radio commentators too—but just the same, Uncle Sam isn't going to toss his weapons away right now. Delicate and expensive war equipment will not be scrapped, but instead will be scientifically sealed in specially built containers and treated by a recently developed process that will preclude the possibility of corrosion, decay or other deterioration which under normal conditions would attack such equipment in time.

It has always been a difficult and expensive job to store away the materials of war. According to former methods, machinery had to be greased and stored in warehouses which were frequently constructed especially for the purpose and which required some type of maintenance and temperature control. Degreasing prior to eventual use is also a costly, time-consuming process.

At Dravo Corporation's Neville Island Plant near Pittsburgh, generating units, height finders, and directors are being stored in all-steel hermetically-sealed containers. The size and shape of the container is determined by its purpose. As soon as the container is filled, the vessel is completely welded and the air pumped out. Then nitrogen gas is forced in. Nitrogen, an almost inert gas, won't react with the metal or anything else in the apparatus.

Silica gel—a chemical dehydrator—is put into the container. Silica gel absorbs any trace of moisture which might still be clinging to the inside of the containers and is capable of absorbing many times its own volume of moisture.

Temperature changes varying from 20° F. below to 140° F. above zero won't harm the contents of these containers. They can be stored in the open in any place that has the necessary area. This type of packaging has another advantage in that it eliminates the use of warehouses, which have always been choice targets for bombers or saboteurs. Containers in this case can be widely dispersed and separated. They can be easily concealed.

Not all military equipment need be stored, because some of it is sure to be obsolete in a year or two. Precious optical instruments, some special weapons, fire control apparatus, and a number of other items lend themselves to storage and will be as effective when removed from the containers some years hence as they are today. The containers being built by Dravo Corporation are for the Army Service Forces, Ordnance Department, Frankford Arsenal, Philadelphia. All engineering services in connection with their design and fabrication were performed by Dravo.

This all-steel hermetically-sealed storage container for a generating unit is getting final check.

The new CCA Filter-Lube, compact pneumatic filtering unit combined with a precision lubricator.

CCA Filter-Lube Announced For Pneumatic Equipment

CCA Filter-Lube, a compact pneumatic filtering unit combined with a precision lubricator, is announced by CCA Products Engineering, Glendale, California. Its primary use is for installation as close as possible to the equipment it is intended to service, including air cylinders, vises, chucks or any reciprocating or rotary air tools.

Designed to prolong the life of all types of pneumatic equipment, prevent freezing of air-operated devices, and deter the inroads of corrosion, the CCA attachment is the latest development in a long line of industrial equipment by this manufacturer.

Available in 1/4", 3/8" and 1/2" standard pipe line sizes, it is simple to install on air supply lines. It features a full-view, lightweight, transparent plastic lubricator oil reservoir, enabling the operator to see at a glance the quantity of oil in the element.

A needle valve oil regulator, easily adjustable to meet all varying lubrication requirements, permits the correct amount of oil to mix with filtered operating air.

The lower element is composed of a sludge basin of ample size and an all wool felt filter medium. Fully automatic in operation, the device first filters incoming working air, and next provides a finely adjusted lube-mist, perfectly regulated according to equipment requirements. Through use of the device, no flood of oil is permitted to enter working equipment, and no oil starvation is possible, thereby eliminating loss of equipment and man-hours in adjustments and repairs.

The felt filter medium, interchangeable and reconditionable, guarantees protection against free moisture, oil sludge, dust clogging, corrosion or pitting. Filter-Lube functions only when equipment is in operation.

Lightweight Generator

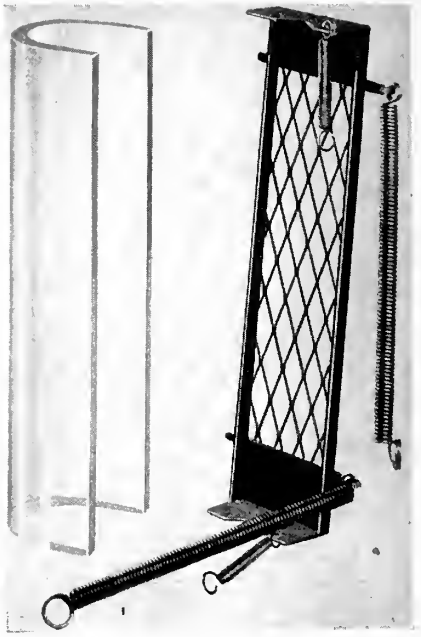
A generator weighing but half as much as formerly available equipment but capable of supplying up to 1200 watts in continuous duty is announced by Electrical Engineering and Manufacturing Corporation, Los Angeles, California.

Originally developed as an airborne unit for remote radar stations, this especially designed EEMCO unit has a maximum weight of 20 to 25 pounds, depending upon rating. Available in 500, 600, and 1200-watt capacities, at 32 and 120 volts, 50° temperature rise, this generator is the totally enclosed, glass-insulated type, and is equipped with lifetime-lubricated ball bearings.

It can be supplied as a two-bearing unit, or with a single bearing for direct-drive applications. An integral panel with meters and voltage regulator is also available.

Small in size, light in weight, and built for continuous-duty operation, this new unit has many uses for auxiliary power generation, as well as for primary power in a variety of marine, rural and commercial applications.

Lightweight generator.



Transparent gage glass protector.

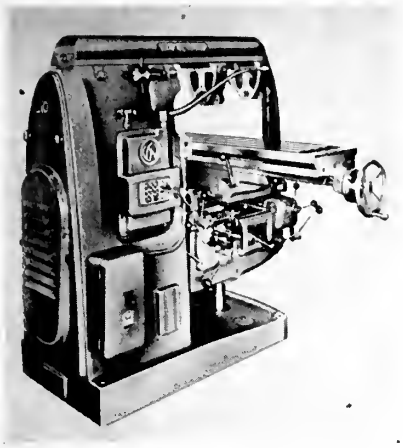
Transparent Gage Glass Protector

The Wright-Austin Company, Detroit, Michigan, has recently developed a new type of gage glass protector, trade-named "Kleervu." This protector consists of two simple parts — the metal frame, with four holding springs, and a quarter-inch thick transparent "Nuglas" cover. C. B. Walter, general manager, tells us that installation is very simple, taking but a couple of minutes.

When installed, the "Kleervu" encloses the gage glass within a protective transparent cover, so that should the gage glass burst or explode, all flying broken glass is safely confined within this shatter-proof enclosure, eliminating danger of injury to persons.

In the back is a screened frame which holds the cover and provides an open vent area for escaping steam in case of gage glass breakage, thus avoiding any pressure build-up within the protector.

"Kleervu" gage glass protectors are now available in any desired length for tubular gage glasses on boilers, process tanks, chemical tanks, oil tanks, cooker and other installations. Descriptive literature sent on request to the manufacturer.



No. 3 standard horizontal milling machine.

New Standard Horizontal Milling Machine

The Van Norman Company, Springfield, Massachusetts, announces a new No. 3 horizontal milling machine especially designed for a wide range of general purpose and production milling. A large heavy duty miller, it has a 64-inch by 14-inch table, permitting the user to handle heavy work. This machine is unusually compact, with exceptional rigidity and dependability assuring smooth operation on the heaviest cuts. It combines rugged strength with utmost accuracy and extreme sensitivity of operation and control.

An important feature of the new transmission includes a heavy large diameter flywheel mounted on the spindle inside of the column, assuring smooth, uniform application of power to the cutter.

A few operating specifications are: table 64″ x 14″, drive motor 7½ hp, table travel longitudinal 34″, saddle cross feed 12″, knee vertical feed 17″. Eighteen speeds are available from 25 to 1250 rpm; 18 feeds from ⅜″ to 32″. The miller is available with plain or universal saddle. The universal saddle permits the table to be swiveled 45° to the right and 45° to the left.

Zircoat-M

Zircoat-M is a zirconium silicate base refractory developed by Basic Refractories, Incorporated, which upon application with a spray gun sets up rapidly to form a hard, dense working surface that will withstand high furnace operating temperatures and unusual furnace conditions. It is a fine-grained material shipped dry in 100-lb. bags. It is mixed with water for spraying and has been extensively used as a protective coating on silicon carbide, fireclay, sillimanite, mullite, silica and other acid type refractories.

It has been widely used with success in the industrial boiler field in protecting brickwork that is exposed to severe flame impingement and corrosive action of clinker or fly ash.

Applications of from ⅛″ to ¼″ on the inside brickwork of marine boilers have increased the continuous operation of such units between repair lay-ups from two months to six and eight months.

Safety Floor Covering

Economy, ease of application and maintenance, plus a high degree of anti-slip efficiency, are features of Ferrox, a lightweight non-slip composition made by American Abrasive Metals Company of Irvington, New Jersey. This product is a synthetic resin containing an abrasive. It will adhere to metal, concrete, or wood surfaces, and may be applied by trowel or spray gun. Where principally foot traffic is encountered, it provides a highly serviceable, low-cost safety surface.

Ferrox was originally developed to meet the requirements of the U. S. Navy for a lightweight, slip-proof deck covering. It was the first of its type to be used by the Navy. Hundreds of thousands of square feet have been used since 1941 on all types of vessels, from the small PT boats to battleships. Ferrox has served as well for uses by the U. S. Army Engineers and by several leading aircraft manufacturers.

New Grease for Ball Bearings

For dependable lubrication from 13° F. to 176° F. for all speeds up to 3600 rpm and for horizontal or vertical operation, an improved grease for ball and roller bearing motors is announced by the Westinghouse Electric Corporation.

Available in a new eight-ounce nasal type tube, the grease is stable, highly resistant to oxidation, and will remain in a bearing for an indefinite period without drying out, caking or separating. The new tube is designed for easy and economical use. It has a large opening in the long nasal spout which fits into a one-eighth-inch pipe coupling, and a key with which to wind and exert pressure from the bottom of the tube.

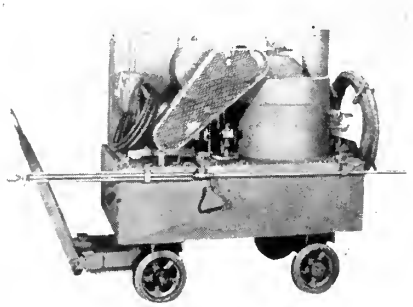
Oakite-Vapor Cleaning Unit

Oakits Products, Inc., has developed a new, multiple-duty steam cleaning unit known as the Oakite-vapor cleaning unit.

This unique unit is a self-contained, down-draft flame, oil-fired, enclosed coil-type steam generator that delivers hot vaporized cleaning solutions under selective pressures up to 200 lbs for the speedier, easier removal of grease, grit, grime, paint and other deposits from surfaces. A wide range of fuel oils such as No. 1, No. 2 or No. 3 fuel oil, kerosene or gasoline, may be used to operate the unit. Due to its flexibility of steam pressures, the unit may be used on many different types of light and heavy-duty cleaning.

Extremely rugged in construction, only the highest quality materials are used in the manufacture of the Oakite-Vapor cleaning unit. Built for long, continuous, trouble-free service, the unit has tremendous reserve power and operates without vibration. Many new, exclusive features are incorporated that provide for simplicity and ease of operation and maintenance, rapid steam generation, unusual solution tank capacity, effective operation of two steam guns simultaneously, wide flexibility in its application to various cleaning operations, safety against fire (A.S.M.E. safety code standards are fully met) and other advantages.

Oakite-vapor cleaning unit.



Post-War Line of Marine Gages

A complete new and improved post-war line of marine gages to provide modern boat owners with accurate, dependable indication of fuel and water level, rudder angle and reverse gear position, is now in production at the Liquidometer Corporation, New York.

This company has completed its program of reconversion and is now in a position to supply boat builders, dealers, ship chandlers and pleasure boat owners with various types of Liquidometer gages in price ranges to fit every class of vessel.

Liquidometer's line of instruments is designed to take the modern boat owner out of the "horse and buggy" stage, and features: an economical direct-reading liquid-level indicator for mounting on the top, side or end of a tank; the type "L" levelometer, distance-reading hydrostatic indicator; a distance reading, float-actuated electric fuel level gage that eliminates danger of old electric gaging systems by use of metal bellows seals at tank fittings to prevent escape of vapor or fuel; a distance-reading hydraulic gage employing a fully temperature-compensated, balanced hydraulic transmission system that does not depend on any outside source of power. An electric rudder angle position indicator is also available. The same hydraulic transmission system used in the fuel gage can be furnished for transmitting any kind of motion, such as rudder angle position or the position of the reverse gear.

New Plastic Fabric Finds Varied Application on Watercraft

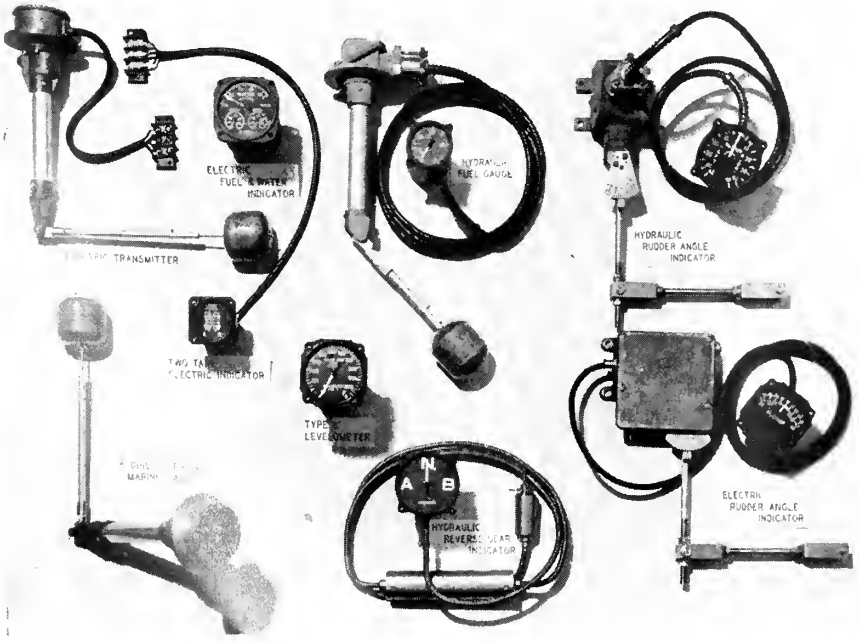
Textasote G., a new plastic coated duck fabric, manufactured by The Pantasote Company, Passaic, N. J., is finding wide application on ships, boats and watercraft.

The new fabric is flame resistant, mildew resistant, easily washed, and has excellent aging characteristics. It is waterproof as well as highly resistant to wind, sun, and weather.

On privately-owned new or reconverted craft and commercial vessels, Textasote G is being used as awning and upholstery material above and below deck. The colors do not fade or wash out due to spray, salt water or rugged boating usage.

Samples will be furnished upon request.

New instruments now in production by the Liquidometer Corp. for use on pleasure boats and small commercial craft include: left to right, top: float-actuated electric transmitter for fuel and water tanks; electric fuel and water level indicator for three tanks; float-actuated hydraulic fuel gage; hydraulic rudder angle indicator; left to right, lower: float-actuated direct-reading gage with three-inch-diameter dial for mounting on top, side or end of tank; electric fuel and water indicator for two tanks; type "L" Levelometer hydrostatic fuel and water level gage; hydraulic reverse gear indicator or engine room telegaph; and electric rudder angle indicator.



New Construction Principle In Flexible Tubing

A new type of flexible tubing, non-collapsible under plus or minus pressures and retractable to about one-eighth its extended length, is announced by the Warner Brothers Company, Spiratube Division, Bridgeport, Conn., for portable or semi-permanent ventilation or any handling of air, gases or light solids. Its spring steel helix core causes it to spring out, like a jack-in-the-box, to its fully extended length, and it will stay in this position regardless of whether it is working on pressure or suction.

A feature of the tube construction is the method of spiral-stitching the spring core within the fabric. The inside surface is free of wire ridges, providing far less resistance to air flow and no obstruction to the passage of solids. Sharp bends can be made with only slight reduction of air flow and without the use of elbows or special fittings.

This new tube is considerably lighter than metal duct or molded tubing, and takes up less space when retracted. The standard spiratube is made of long-fiber duck, having a bursting strength of 170 psi; the fabric is processed fire-resistant and covered with tough, durable thermoplastic. It can also be made to specification in a variety of other fabrics for special applications. Spiral stitching is done with a double seam of rot-proofed thread. There is no exposed metal inside or out (even the couplings are covered), eliminating the possibility of sparking where explosive or inflammable materials are present.

Spiratube has had two and one-half years of service in the U. S. Navy, being used in shipyards, vessels, and advance bases, and has already been given a thorough trial in industry.

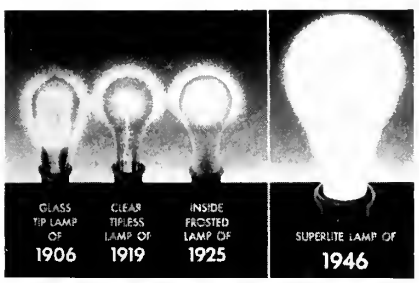
Section of Spirotube flexible tubing. Such sharp turns are made with only slight reduction in free air area.

New Light Conditioning Bulbs Available

After five years of continuous production on U. S. light bulb and photolamp war contracts, Wabash Appliance Corporation, Brooklyn N. Y., announces new improvements in light bulbs now available for civilian allocation.

Heading the list is the white light conditioning bulb, which Wabash compares with the tungsten lamp of 1906 and the clear lamp of 1919, as the most important development since the frosted lamp of 1925. A new process, the company says, treats the glass on the inside of the bulb to diffuse the central glare point caused by the concentrated filament, with the result that the direct raw light rays are broken up into millions of softer "counter diffusing" light rays that glow evenly over the entire bulb surface, without sacrifice of visible illumination.

Wabash states that over forty million light conditioning bulbs of this type have been tested in use over the past five war years, and that substantial shipments are already being diverted to civilian outlets now that Government purchasing has been curtailed. Ten sizes from 10 to 200 watts will be made in 115, 120 and 125 volts, with four sizes from 25 to 150 watts in 220, 230, 240 and 250 volts. Other bulbs being announced include new types of photoflash bulbs and other photographic lighting units, ultra-violet and infra-red heat lamps.



New light conditioning bulbs.

H. F. Gelhaus Returns

Henry F. Gelhaus has returned to San Francisco after approximately five years with the Todd Shipyards Corporation as assistant general manager of their Brooklyn yard.

He is now Pacific Coast sales manager for the company with headquarters at 486 California Street, San Francisco.

He is well known on the Pacific Coast and for many years was marine superintendent for the Swayne & Hoyt Company.

Small Portable Searchlight

Kenyon Instrument Co. Inc., Huntington, L. I., manufacturers of marine and aviation precision equipment, announce development of a small portable searchlight capable of throwing an 80,000-candlepower beam a distance of two miles.

Small, well-balanced, and designed to operate either by hand or on a ball-and-socket mount attached to a ship's rail, this searchlight is directable through any arc. A lightning-fast micro-switch, mounted in a trigger grip, makes the new light a perfect signaling device. Another feature is a built-in plastic beam-sight which provides a pilot light and a glowing aiming bar.

The searchlight will be produced in two models, one designed for six-volt and the other for 12-volt operation. Both models are of 80,000 candlepower.

Small portable searchlight.

Tide Tables for 1946

The Shell Oil Company is distributing a well-prepared 48-page booklet giving tide tables for over 90 points on the California and Mexico Coasts. The tidal variations are based on the figures for Los Angeles and San Francisco harbors, and are indicated for every day of the year.

The booklet also contains towing signals, weather signals, and various useful information for mariners.

Marinship's Record Filmed

Dramatic story of one of the Pacific Coast's finest wartime shipyards has been recorded in an hour-long colored sound movie which is now available for showing by Marinship Corporation of Sausalito, California.

Narration by John B. Hughes accompanies the film, which includes historic views of the first keel laying on June 27, 1942, first launching on September 26, 1942, and many other important events during the succeeding three years. At Sausalito Marinship employees built a $17,000,000 shipyard and 93 EC-2 Liberty ships and T-2 tankers. The tankers were 10,000-horsepower Mission class merchant tankers and oilers and 8250-horsepower Hills class merchant tankers.

After three years of preparation, the motion picture was completed only recently. It is now available to interested groups for showing, according to R. W. Adams, employee relations manager, Marinship Corporation, Sausalito, California.

Therm-O-Sol Kills Corrosion on Metals

In Therm-O-Sol, Harry W. Parsons, Inc., has developed an answer to the problem of corrosion following the pickling and descaling of metals. On steel the corrosion rate is less than that of most city drinking water, .0035 per year; while on copper and copper alloys an actual build-up or permanent plate forms on the surface of the metal pushing the scale off.

Their recommendations are:

Therm-O-Sol A for evaporators and other vessels containing hard scales formed at over 200° F. and containing a combination of steel and copper alloys.

Therm-O-Sol B for pickling operations.

Therm-O-Sol C for evaporators, condensers, or other heat exchangers containing steel and copper alloys and operating under vacuum.

After the wear and tear of hard wartime usage with unskilled help, rising costs of new equipment can be combated by making pressure vessels last out their life expenctancy by descaling the Therm-O-Sol way.

Equipment can be returned to service in from 20 to 72 hours.

On the Ways — SHIPS IN THE MAKING

S. S. Arizona Pine, which was recently launched at Albina Engine & Machine Works. This ship is one of a series of lumber ships being constructed by Albina, featured in August 1945 Pacific Marine Review.

Arizona Pine Launched At Albina

The last of 765 Maritime Commission ships built in Portland since the start of World War II was launched at Albina Engine and Machine Works on January 5, as Mrs. Stanley G. Jewett cracked the bottle of champagne on the bow of the Arizona Pine, fourth of the lumber ships designed by Albina's president, L. R. Hussa.

Santa Rosa Nabs Pennant in Pacific Redeployment Race

Vieing to beat her own record performance as America's fastest troop transport in service between New York and the China-Burma-India theater, the Grace Liner SS Santa Rosa, which recently completed the 16,000 mile turn-around voyage in forty days and fifteen hours has just sailed from New York under the command of the veteran Master, Captain Duncan Cook, of Rowayton, Connecticut, with 120 passengers bound for Port Said, Egypt, and Karachi, India.

Completion of the current record-breaking voyage with a complement of 2446 GI's and one repatriated merchant seaman aboard brings the total number of troops carried during the war by the Santa Rosa up to the 100,000 mark. The vessel came to the coast on her maiden voyage, December, 1931, and continued to sail between Pacific Coast ports, Havana and New York in the Grace Line service until January, 1938. Then she was transferred to the New York, Atlantic and the Orient services.

Included among the passengers embarked on the Santa Rosa are a party of missionaries bound for Nairobi, Kenya; Indian merchants and traders returning home to implement commercial and export program; and 23 civilian employees of a United States oil refinery in the Middle East.

Among those sailing are:

Robert Morrisey, United States Vice-Consul to Egypt.

Philip Cottell, United States Vice-Consul to Palestine.

Donald Bergus, United States Vice-Consul to Greece.

George Arnold, United States Commercial Attache to the American Legation in the Lebanon.

Hans Raj, American representative of Zamindar Sports, Ltd., Sialkot City, India.

Consolidated Steel Launches Fifth of a New Series

The SS Mountain Wave, the fifth of a fleet of ten huge C-2 cargo vessels, was launched from Consolidated Steel's Wilmington shipyard. Mrs. Morris, wife of Samuel B. Morris, general manager and Chief Engineer of the Los Angeles Department of Water & Power, was the sponsor.

The SS Mountain Wave, together with her nine sister ships, are the largest vessels to be built at Consolidated's Wilmington yard.

These C-2's are 460 feet long, have a beam of 63 feet, and a molded depth of 40′ 6″. They are of 14,000 tons displacement, and their design includes comfortable accommodations for eight passengers, besides the space for cargo.

AMERICAN BUREAU'S RECORD OF PACIFIC COAST SHIPBUILDING

Western Pipe & Steel Co., S. F.	4	C-3's Totaling	48,000 dwt.
Reliable Welding	1	Cargo Vessel,	1,000 dwt.
Kaiser, Richmond, California	2	C-4 Vessels,	29,000 dwt.
Kaiser, Vancouver, Washington	8	C-4 Vessels,	160,000 dwt.
Consolidated Steel Co.	3	C-1 Vessels,	15,000 dwt.
Consolidated Steel Co.	10	C-2,	90,000 dwt.
Albina, Portland, Oregon	3	Cargo Lumber,	10,271 dwt.

Making a total of 31 cargo vessels at 354,171 dwt.

Miscellaneous

Consolidated, Newport Beach	2	Tuna Clippers,	680 gross tons
Hickinbotham Bros., Stockton	2	Tuna Clippers,	1080 gross tons
Judson Pacific	1	Steel Barge,	40 gross tons
United Concrete Pipe Co.	5	Tuna Clippers,	2040 gross tons

(The above construction record was compiled for the month of December, 1945)

Bids for Passenger Vessels For South American Trade

The United States Maritime Commission has invited bids for the construction of two 28 knot 670 foot, twin-screw, turbine-driven passenger vessels for the South American trade and for four 560 foot, single-screw, turbine-driven cargo vessels.

The 670-foot South American liners, fastest merchant vessels ever built in the United States, will carry 543 passengers and 8550 dw. tons of cargo. They will be powered by steam turbines developing a total of 55,000 hp and driving twin-screws. Contractors may bid on one or both vessels.

Bids on the four dry cargo ships are asked on behalf of the Ore Steamship Corporation of 25 Broadway, New York. The 560-foot, C5-S-AX1 type vessels have a dwt of 24,000 and are powered with an 11,000 hp steam turbine driving a single screw to give the ships a speed of 16 knots. Contractors may bid on 1, 2, 3 or 4 vessels.

Bidding is limited to American citizens and all labor and materials must be done within the continental limits of the United States.

Bids for the passenger ships will be opened at 12 noon EST March 28, 1946, and those for the dry cargo vessels at the same hour February 11, in Room 4821, Department of Commerce Building, Washington. Bids and information on the Invitations to Bid are handled by the Secretary of the Maritime Commission, Room 4852.

YEAR-END STATEMENT OF THE SHIPUILDING INDUSTRY

By H. GERRISH SMITH

President Shipbuilders Council of America

During 1945, despite cancellations, there were constructed approximately 10,500,000 dwt of commercial vessels of 2000 dwt or more. The ship repair yards cared for 23,800 vessels of over 1000 gross tons, slightly in excess of the number of ships handled in 1944.

There has been a natural and inevitable liquidation of labor in the shipbuilding industry which has been paralleled in the allied marine industries that supply materials and equipment needed in shipbuilding. Liquidation of labor in the ship repairing industry is much less than in the shipbuilding industry. The demands on ship repair will continue to be heavy for an indefinite time.

Department of Labor statistics clearly indicate that the average hourly earnings in the shipbuilding and ship repairing industry continue to be the highest in the durable goods groups. The total payroll for 1945 for the construction and repair of both commercial and naval vessels in private yards and navy yards was approximately $3,400,000,000.

The industry may emerge from its greatest productive era with employment and orders sufficient to maintain the highly skilled personnel so essential in the designing and construction of the best merchant and navy ships in the world. This personnel represents a reserve of technicians that cannot quickly be trained in a national emergency, such as this nation faced twice in a quarter of a century. Men in this category played a major role in the tremendous tonnage totals produced by American shipyards in the most critical period of world history.

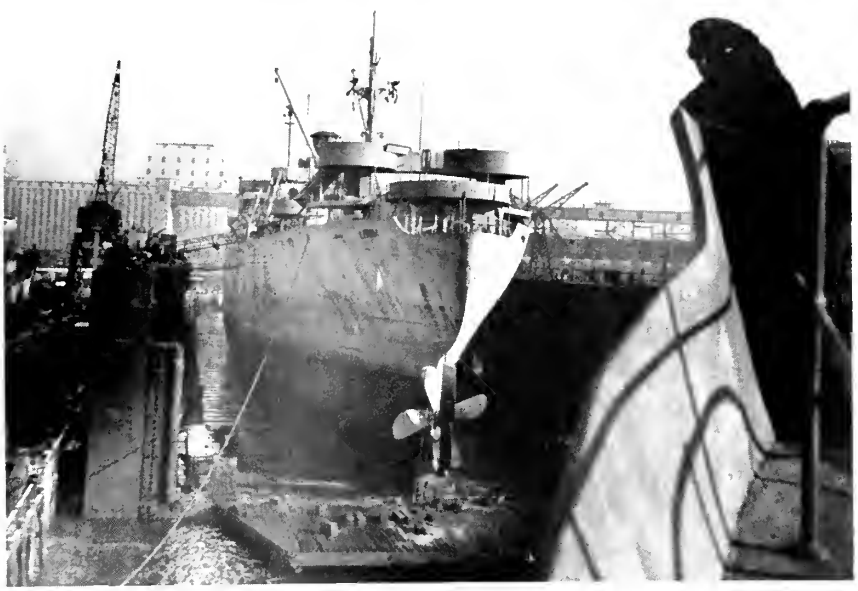
Interocean General Agents for Knutsen Line

For the purpose of placing in the hands of one general agency all the Pacific Coast liner activities of his large fleet of modern motorships, Knut Knutsen, O.A.S., shipowner of Haugesund, Norway, has appointed Interocean Steamship Corporation to handle operations of the following two Knutsen Line services:

(1) Between Pacific Coast ports and United Kingdom via the Panama Canal, and

DAMAGED TROOP SHIP IN SAFE BERTH

Sea water gushes from crack in double bottom of the Liberty ship SS Joseph Hooker, which safely made port with 526 G. I.'s despite leaks and storms. At right, Chief Engineer Louis Fraser of Todd Shipyards Corporation, Brooklyn Division, examines fracture that caused the master of the Liberty to radio for help. Below: the S S Joseph Hooker safely in dry dock after making port under escort of light cruiser Honolulu. She suffered a double-bottom fracture that let eleven feet of water into No. 3 hold.



(2) Between Pacific Coast ports and West Coast of South America.

Sailings to the United Kingdom were resumed from the Pacific Coast in December 1945, and two vessels, the MS Ida Bakke and MS Knut Bakke have already been dispatched. Six fast combination passenger, refrigerator and general cargo motorships of the most modern type are scheduled to be employed in this service.

West Coast South America sailings will be resumed as soon as ships, not under control of the United Maritime Authority, have been released. Vessels which operated prewar include the motorships Marie Bakke, John Bakke, Samuel Bakke, Vinland, Geisha, Nyhorn, Nyhaug, and other units of the Knutsen fleet.

USS Oregon leaving drydock at Puget Sound Navy Yard.
This nostalgic picture belongs with the feature in this issue on Bremerton.

Victories Sailing To the Orient

The American Mail Line has started its post-war program of shipments from Portland to the Orient with a cargo of flour for the Philippines on the Victory ship Gonzaga Victory. The Liberty ship, Anthony Ravalli, is sailing with a load of lumber, building supplies, and general freight for Shanghai. Already on its way to Italy with 8500 tons of wheat for the destitute peoples of Europe, via UNRRA, is the Liberty ship Joel Palmer.

Shortly commercial relations with Hong Kong will be re-established when the China Mail, a C-2 liner, will start loading at Portland and Seattle for the first post-war trip to Hong Kong. The vessel will also touch at Shanghai and Manila as will the Gonzaga Victory and the Waco Victory due to leave Portland in the near future. The Whitman Victory of the same line is due to load in Portland early in February.

NEW LINE-UP OF WORLD'S MERCHANT SHIPPING

In spite of heavy losses inflicted by the enemy the United States emerged from the global war with almost four times as many merchant ships as there were in its pre-war fleet, statistics compiled by the Economics and Statistics Division of the U. S. Maritime Commission disclosed. The gross tonnage of these vessels was almost five times that of the 1939 total.

Thanks to unprecedented shipbuilding during the war years the end of hostilities found the United States possessing 5529 sea-going merchant ships 1600 gross tons and over, against 1401 sailing in 1939.

In that year, less than one-fourth, or 3,000,000 deadweight, were employed in foreign trade. The second largest fleet is the merchant navy of the British Empire, which shows an aggregate loss of only 545 vessels from the 1939 total of 2892 in spite of the concentrated undersea, air and surface attacks by the Axis.

Latest compilations which do not include fleets of the former axis powers, show that during the war the United States lost 604 merchant vessels of 1,000 gross tons and over through direct enemy action. In addition 139 such ships were sunk as the result of marine hazards due largely to war conditions.

The comparative standing of 27 nations having merchant fleets at the close of the conflict is shown in the following table listing vessels except those operating on the Great Lakes and inland waters and special types such as ice-breakers, cable ships and the like:

There are not included in this tabulation vessels acquired by any nation during the war through capture, seizure or transfer and operated under that country's temporary control. Such ships are included in the total of the country from which they were thus acquired.

Included in the United States total are not only vessels which may or may not have undergone some degree of conversion when acquired by the Army or Navy but also military types originally designed as merchant ships and constructed under the Maritime Commission building program. Vessels of a strictly military type and built by the Commission, such as LST's, frigates, aircraft carriers, etc. are excluded from the total.

MERCHANT FLEETS OF THE WORLD

	1939			1945		
Country	No. of Vessels	Gross Tons	Deadweight Tons	No. of Vessels	Gross Tons	Deadweight Tons
United States*	1,401	8,479,953	12,100,200	5,529	40,080,002	56,797,700
British Empire	2,892	17,240,943	23,325,300	2,347	14,842,805	19,589,000

Dominion Republic	1	1,973	2,200	—	———	———
TOTAL	7,921	42,491,958	59,074,400	10,175	65,859,204	91,663,500

*—Includes merchant-type vessels owned by U. S. Army and Navy.

SPONSORS MEDITERRANEAN. INDIA FAST FREIGHTER

Mrs. Marjorie M. Hiltbrunner of Birmingham, Ala., daughter of H. M. Gillespie (left) v. p. and sec-treas., American Expart Lines, christened that company's SS Exbrook, a 9900-dwt. fast freighter intended for the Mediterranean and India trade routes. John F. Gehan, v. p., of same line and Frank Hodge (extreme right) mgr. Bethlehem - Sparrows Point Shipyard, builder of the ship, are shown with the sponsor.

Barge Line Orders Kort Nozzles for Towboats

In a move that ranks as one of the most extensive programs of renovation for improving towboat performance in recent years, Mississippi Valley Barge Line recently contracted with Dravo Corporation for the furnishing and installation of Kort nozzles on the towboats Tennessee, Louisiana, and Indiana. These installations will also include the complete redesign of the stern hull section on each of the three vessels to provide more efficient lines.

The decision to equip these towboats with Kort nozzles came after nearly four years of study of the performance record of the towboat Ohio, a sister ship of the Indiana. The Ohio was Kort nozzle equipped at Dravo's Marine Ways in February 1942 and after conversion was found to have an increased pushing capacity which permitted her owners to increase her fleet tonnage substantially. Similar results are to be expected in the conversion of the other three vessels which are very similar in design.

December Merchant Ship Deliveries

U. S. merchant shipyards closed 1945 with delivery of 19 vessels totalling 150,534 dwt, the lowest monthly deliveries since January 1942 when 16 vessels were put into service, the U. S. Maritime Commission announced. December of 1943 marked the peak of the shipbuilding program when 219 ships were delivered.

Deliveries for the year were lower than 1943 or 1944 and totalled 1,097 vessels for the twelve-month period with a total of 10,598,154 dwt.

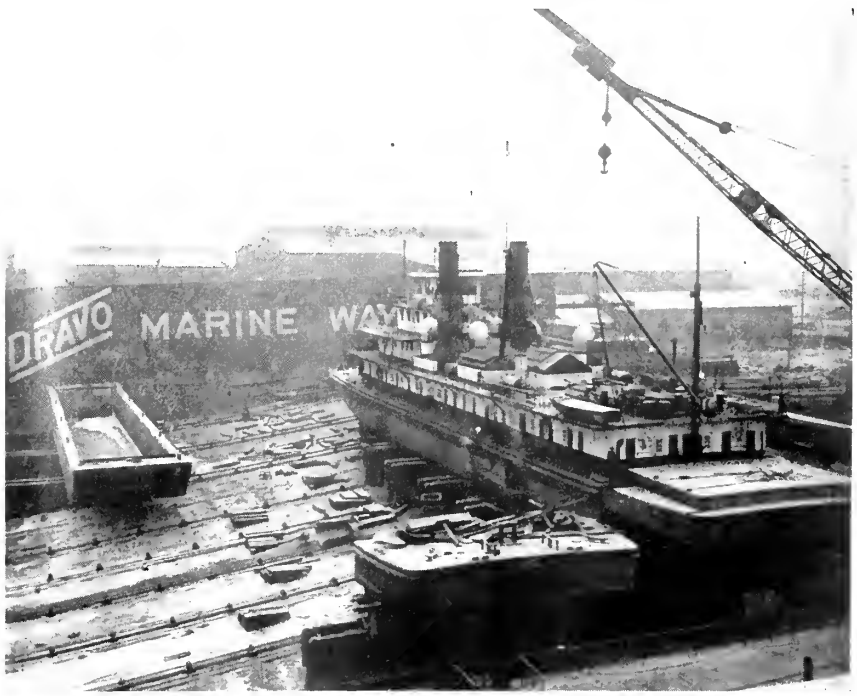
December deliveries included six C-type cargo vessels, five coastal cargo ships, three coastal tankers, two Navy tankers, two private motor coasters, and one refrigerated cargo ship.

East Coast yards delivered 53.4 per cent of the total, including six vessels of 80,339 dwt. Gulf Coast shipyards delivered eight vessels aggregating 54,165 dwt. which netted 36.0 per cent of the month's deliveries and the West Coast yards delivered five vessels of 16,030 dwt., 10.6 per cent of the total.

Deliveries by yards follow:

Shipyard	No. of Vessels	Type of Vessel
Albina Engine & Machine Works	2	Pvt. Motor Coaster
Bethlehem-Sparrows Point Shipyards	1	C-3-S-A3 C-Type Cargo
	1	
Consolidated Steel Corp.	3	T3-S2-A1 Tanker (Navy AO)
Federal Shipbuilding D. D. Co.	1	C-1-M-AV1 Coastal Cargo
Gulf Shipbuilding Corp.	1	C-3-S-BH1 C-Type Cargo
Ingalls Shipbuilding Corp.	2	R2-St-AU Refrigerated Cargo
J. A. Jones Construction Co., Inc. Wainwright Yard		C3-S-A2 C-Type Cargo
	1	T1-M-BT2 Coastal Tanker
North Carolina Shipbuilding Co.	2	C-2-S-AJ5 C-Type Cargo
Pennsylvania Shipyards, Inc.	2	C1-M-AV1 Coastal Cargo
Sun Shipbuilding & Dr·· Dock Co.	1	T3-S2-A3 Tanker (Navy AO)
Todd-Houston Shipbuilding Corp.	2	T1-M-BT2 Coastal Tankers

The adding of a new stern section and Kort nozzles to the Indiana, Tennessee and Louisiana, will be handled in much the same manner as scene below. This picture, taken in 1942, shows the old section set aside and new prefabricated stern section being set into place on the towboat Ohio. Kort nozzles were added later.



IMPROVED ANCHOR

(Continued from page 127)

conventional type anchors and the Danforth Mark II and Mark IV:

	Holding Power in:		
	Very soft mud	Med. soft mud	Hard sand
100-lb. kedge (varying with design)	200-500 lbs.	200-700 lbs.	200-700 lbs.
Mark II			
30 lbs.	750 lbs.	1780 lbs.	6000 lbs.
Mark IV			
10 lbs.	800 lbs.	1600 lbs.	7000 lbs.
25 lbs.	1400 lbs.	2800 lbs.	9000 lbs.

The above figures and the results of many hundreds of tests indicate that it would be conservative to use a Mark IV half the weight of a Mark II in order to secure equivalent holding power.

The new anchor has the same features as the current model, but to a more marked degree; it is non-fouling, easy-to-handle and has the greatest holding power of any anchor ever designed.

Hundreds of thousands of Danfort Mark II anchors in sizes from 17 lbs. to 10,000 lbs. were manufactured in the United States, Great Britain and Canada during the war and were extensively used by Allied armed forces throughout the world. Danforths were used for regular anchoring tasks and astern on all types of craft to haul these vessels back off the beaches. Port repair ships used 3000-lb. Danforths to haul wrecked docks and ships and clear harbors destroyed by the enemy—a spectacular test of Danforth holding power.

PEAK DIESEL PERFORMANCE

(Continued from page 136)

the effects of dirty intake air on cylinder liner, ring and piston condition questions the need of a quality product in this service. Very few engineers, however, realize that where diesels are not operating under dirty conditions, and air intake filters are not deemed necessary, greater engine room comfort in regard to noise and vibration can be secured when properly designed and engineered air intake systems are applied to the engine.

Engineered Exhaust Systems

The too-complete elimination of exhaust back pressure can be nearly as detrimental to peak diesel engine performance as having the back pressure too great. In the first case, the slug of exhaust gas from the cylinder creates a partial vacuum in the cylinder which is immediatedly filled by a resurgence of exhaust gases from its line preventing fuel scavenging. In the second, the back pressure is sufficient to prevent complete elimination of the burned gases with the same result. Considerable operating benefit, cleaner exhaust and better scavenging can be received from having the exhaust system "tuned" to the engine. This can only mean an engineered exhaust system.

Efficient and Reliable Instrumentation

Faulty instrumentation on diesel engines can give almost as much operating trouble as no instrumentation whatsoever. Many a diesel operating engineer has endeavored to correct a rough engine by bringing the exhaust temperatures for the individual cylinders more nearly into line, only to find the engine still rougher after balancing the temperatures nearly perfectly according to the instruments available, and then, by switching his thermometers or thermocouples, find recorded temperatures away out of line. Faulty instrumentation had him giving more fuel to a cylinder that was already getting too much.

Instrumentation that will allow periodic check of both compression and firing pressures and used in conjunction with exhaust temperatures will give smooth peak operation and indicate correctional procedure for difficulties before they become serious. Instruments to check injection operation periodically for pressure, spray pattern, and fuel quantity are big aids in preventing trouble. Accurate gages to indicate oil pressure, oil temperature, cylinder cooling water temperatures in and out, raw water in and out temperatures, fuel pressure, scavenging air pressure, crankcase pressure, rotational speed, exhaust temperature from each cylinder, give the operator running indications on engine conditions, and, intelligently used, pay big dividends in maintaining performance.

Summary

Detailed consideration of the various factors governing peak diesel engine operation lead to but one conclusion; i. e. the choice of accessory equipment to meet the specific conditions under which the engine must operate is as important as the proper selection of the engine itself.

Running LIGHTS

Edited by B. H. Boynton

"WELL DONE . . . WELCOME HOME." The Red Cross volunteer is at the pier to greet every returning transport. Throughout the war Red Cross has served at the docks and will continue to work there until the last troops are home.

Red Cross Still Hard at War Work

The Red Cross, a friend through the war years to the wounded, the man overseas, the returned veteran and his family, still feels its job is only partly finished. Overseas there are several thousand ARC field workers remaining on duty until the last American soldier is brought home. In the hospitals, their service is tremendous with recreation and welfare programs, and its Gray Ladies.

Some idea of the task confronting the Red Cross may be seen any day at the docks where thousands of returning servicemen stream across the piers and are met, day and night, by the ARC volunteers. The canteen workers have seen off every transport, giving a parting wave and some small comfort to the men going out to fight. Today, Red Cross remains at the docks, serving as many as 30,000 a day, of those same returning men. This Christmas was an example, when shiploads of high point veterans were stranded at Pacific Coast piers. The Red Cross set up emergency canteens and worked the clock around, also finding time to give each veteran a Christmas gift.

With all this and other services too, the Red Cross must assume community obligations formerly curtailed by war. The nation is asked to quickly raise the 1946 Red Cross fund.

Seated: PMR's scribe, Mrs. Claude B. Mayo, and Mrs. Frank Short. Rear Admiral Giles C. Stedman gave an informal interview at the January meeting. He assumed the rank of Rear Admiral in the Naval Reserve at an impressive ceremony at Kings Point. President Truman made his nomination on October 6 and the Senate confirmed the appointment later that month. Admiral Stedman, a modest hero, a keen and able administrator, is a native of Quincy, Mass. He has been associated with the Maritime Academy since the summer of 1942.

Maritime Academy Day at Women's Meeting

The Women's Organization for the American Merchant Marine was honored by a visit from two leading maritime figures, guests at the January meeting. They were Rear Admiral Giles C. Stedman, USNR, superintendent of Kings Point Academy in New York, and Captain Claude B. Mayo, USN (retired), superintendent of the California Maritime Academy. Guest of Captain Mayo was his aide, Lieutenant A. M. Barlow, former aide to Admiral Stedman at Kings Point and former graduate of the Academy.

Admiral Stedman was in San Francisco for a few days around the first of the year and paid the WOAMM's an informal visit during the luncheon honoring Captain Mayo. Stedman has been on tour of the various Maritime Academies, after spending several months in Washington, D. C., on a special assignment.

During each of their talks, both officers emphasized the need of intensified training of the youth to the sea, in order to maintain and operate a strong merchant marine. This need of highly skilled officers to handle our great merchant fleet is growing with the expansion of peacetime trade. Therefore, it is important that the various State Maritime Academies supply the skill in men, through a rigid three year course, comparable to the training of our skilled professional men.

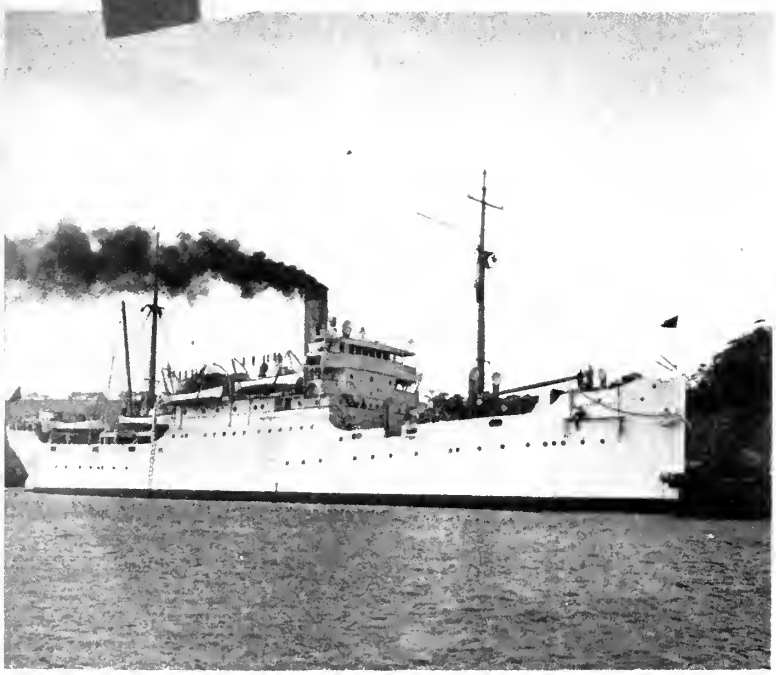
Stedman gave a brief account of the National Maritime Academy at Kings Point, and Captain Mayo explained the functions of the California Academy, a State operated school. He also lauded the young men graduates that have performed so well during this war.

There are five State Merchant Marine schools. One is in Maine, started in 1941; one is in New York State at Sheepshead Bay, started in 1876; another in Massachusetts and one in Pennsylvania, each started sometime in the '80's; and one is in California, started in 1929.

Captain Claude B. Mayo, USN (retired), addressing the Women's Group. Seated to the left is Mrs. Frank Short, president of group, and across from her is Mrs. Harry W. Parsons and Lt. A. M. Barlow, aide to Captain Mayo.

S.S. Golden State

At top: Cadet Midshipmen applying the finishing touches to the school ship.



Center: Training ship, S. S. Golden State, steams up prior to sailing out of Morrow Cove, out of the Golden Gate, and out—for her first peacetime cruise to South America.

Below, left: Midshipmen coming aboard for a stay of two and one-half months. During this cruise they combine theory with actual experience. While on the cruise the cadets form the crew of the vessel. They will visit Acapulco, Balboa, Callao, Peru, and Valparaiso, Chile. At right: Recreation is provided on board and the student crew supplies the talent.

The California Maritime Academy school ship got back in its stride when on January 10, midshipmen from the Academy carried their duffle bags aboard the training ship, S.S. Golden State, and settled in for a two-and-one-half months cruise to South America, taking in such ports of call as Acapulco, Balboa, Callao, Peru, and Valparaiso, Chile. The best part of the training program, to the students way of thinking, is this period of training when they pull up anchor and sail out the Golden Gate. For the duration of the war, these cruises were limited to San Francisco Bay but before the war, the school ship sailed on very ambitious cruises, including circumnavigation of the world; round South America; Hawaii, New Zealand and Australia; and intercoastal to the Atlantic ports of the United States.

This ship is an integral part of the Academy. During intervals between cruises she is berthed at the Academy dock. Here the midshipmen stand watch and do repair and maintenance work. Steam is kept up and the vessel is continually in use for demonstration and even classroom purposes. Now, while on cruise, the midshipmen are the crew of the vessel and do all the work, as the ship carries no sailors or firemen.

Twelve Navy officers sail with the midshipmen as instructors. Most of the officers on the staff and instructors at the Academy are graduates, either of this State Academy or some other Merchant Marine Officers' School, with the exception of Captain Mayo.

Sails for South America

The California State Academy building grounds cover some 70 acres. At present, it has a capacity for 150 men. At the last opening for students, the school received some 2600 applications. Out of that number 650 men took the examination and the Examining Board accepted 40 California men. During the three year course of training, the cadet midshipmen makes three cruises of from two and one-half to four months each, then spends 21 months in academic classroom training, and receives a 30-day leave each year.

Captain Mayo USN, (retired), superintendent of the Academy at Morrow Cove, Vallejo, California, when recently lauding the graduates of the school, said that since the school has been in operation they have graduated over 600 officers. Around 100 of these men hold masters licenses; over 100 of them are chiefs and others certificates. Two graduates have held the coveted position of chief engineer for over 18 months on navy ships during the war, one on the USS Pennsylvania and the other on the USS Nevada. During the war, the training time was two years and graduates were awarded licenses as Third Mates or Third Assistant Engineers, a commission as Ensign in the United States Maritime Service, and a commission as Ensign in the United States Naval Reserve. This new class has gone back to peacetime requirements of three years, and graduates will be awarded a Bachelor of Science Degree and will probably receive a license as Second Mate or Second Assistant Engineer, in addition to their commissions in the United States Naval Reserve and United States Maritime Service.

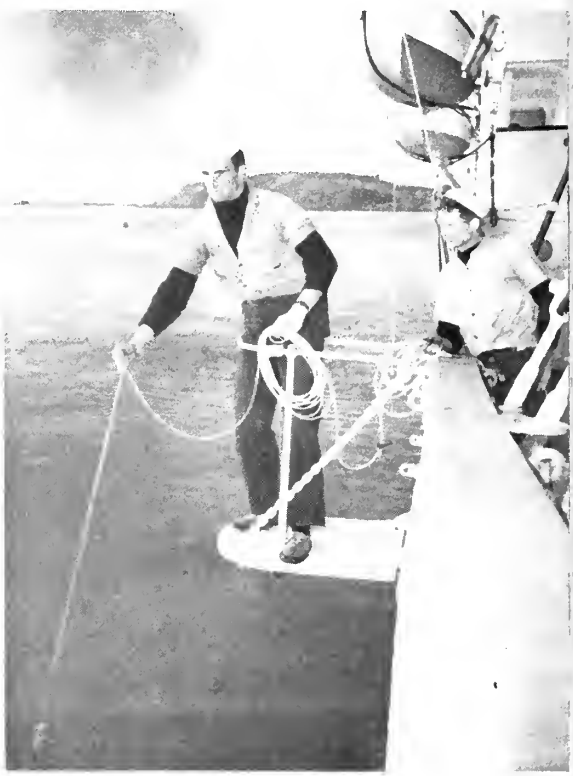
The future of the shipping industry and maritime commerce depends on well educated and experienced officers.

Now the training ship, S.S. Golden State is plowing her way south of the border. But at other schools a new quota of 15 men a week will be accepted by the U. S. Maritime Service Recruiting offices in San Francisco as resumption of training for peacetime careers in the merchant marine. Sixteen men have been accepted as candidates between the ages of 26 and 35, these men, as well as qualified veterans, will be sent to the U. S. Maritime Service training station, Sheepshead Bay, New York, for deck, engine or steward department instruction.

Transportation to the East Coast, plus uniform, quarters, subsistence and $50 per month cash allowances are provided by the Government.

Interested applicants should contact the U. S. Maritime Service Enrolling office, 1000 Geary Street, San Francisco.

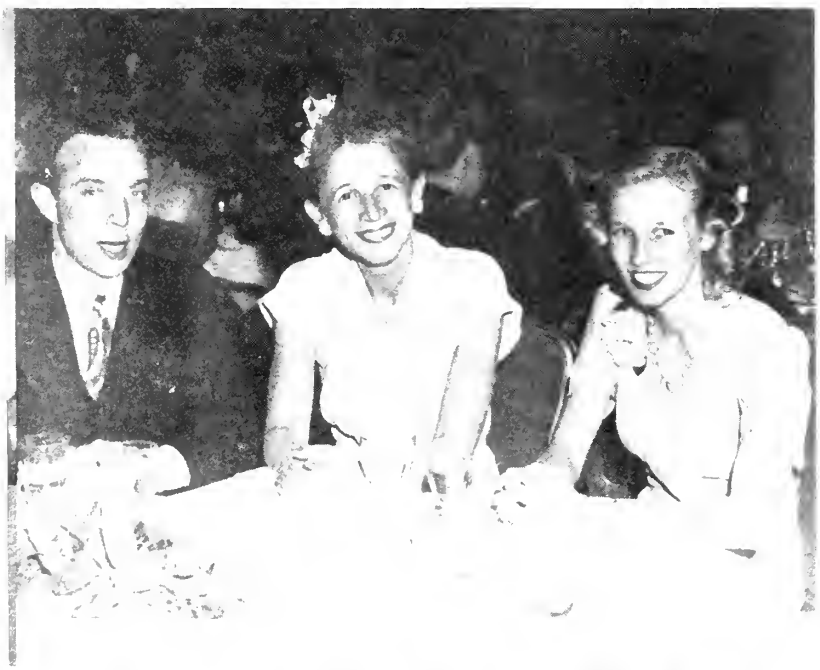
Captain Mayo, USN (retired), is handing over final instruction and bidding goodbye to Captoin Lester Martin, USNR, skipper of the S.S. Golden State, former skipper of an LSD during the war, and wearer of the Bronze Star.



Cadets receiving instruction on sextant reading by Lt. Comdr. C. H. Tubbs. Left to right: Curtis Harrison, Melvin Pollins, Raymond Wilson, John C. Welch, Jr., and Joseph Karasky.

S.F. Propeller Club 5th Annual Dinner Dance

HELD DECEMBER 15 AT THE ST. FRANCIS



Head table, left to right: Ed Harms, James E. Keller, guest from the Los Angeles Bilge Club, ond affiliated with the Pacific Coast Cement Institute of Los Angeles; W. R. Chamberlain, J. J. Geary, president of the San Francisco Propeller Port, J. A. Moore, Jr., retiring president; E. Russell Lutz, George E. Swett, Captoin Paul Cronk and Gene Hoffman.

CHANGE OF HELMSMAN

San Francico Propeller Port

The new administration of Joseph J. Geary, 1946 president of The Propeller Club, Port of San Francisco, got under way impressibly at the January 16th luncheon meeting when retiring President Joseph A. Moore, Jr. offered his valedictory remarks to an appreciative audience, turning the gavel over to the new helmsman, and his duly elected governing board.

Presentation of a beautiful gift in behalf of the membership was made to Mr. Moore. The selection, we understand, was a magnificent ultra-modern radio job (which was not unveiled because of the "fitness of things").

To hear the swan song of our retiring leader, a dignified rooting section came aboard . . . comprised by Joseph A. Moore, Sr., Austin Sperry, Charles Bulotti, Roy Folger, Nat Levy, and other friends of the Moore Dry Dock Company, where "young Joe" is the able president. Roy Folger seized the opportunity of making some dignified remarks, and gave The Propellers and their guests a rollicking

Rudy De Gorog, catering superintendent of Matson, receives a token of appreciafrom club members through Gene Hoffman.

ten or twelve minutes. Secretary Gene Hoffman, still the Club's official story-teller was next on the bill, and with a neat genuflection to Folger, managed quite well to "follow the acrobats."

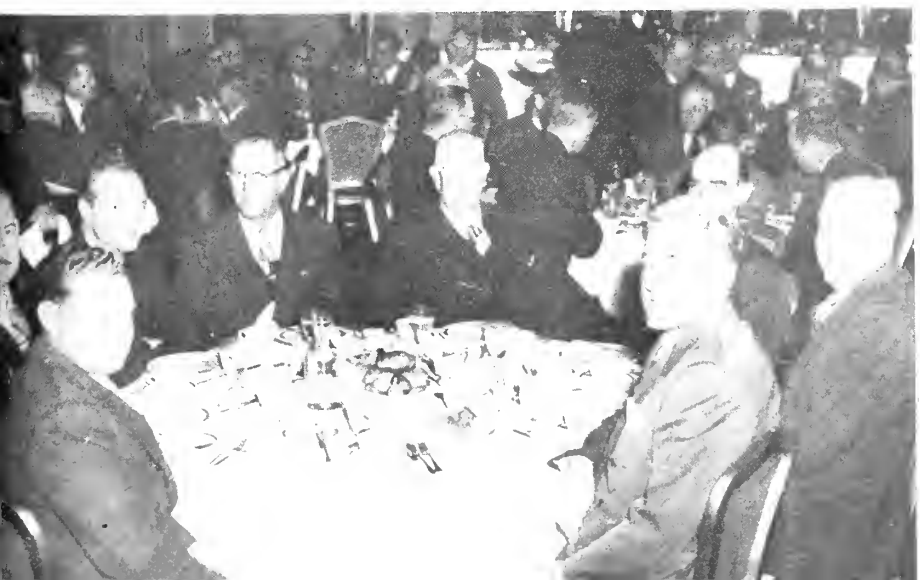
The man responsible for the excellent service which the Club has enjoyed during 1945 received the dining spotlight of appreciation! Rudy De Gorog, catering superintendent of Matson, deft member of the House Committee, was the receipient!

Among the guests in attendance was L. Godfrey Waters, proposed chairman of the board of General Engineering and Dry Dock Company. Mr. Waters attended with the President, George A. Armes.

The new members introduced during the meeting were: M. J. Burress, manager, Crane Company; Peter Howard, superintendent, Howard Terminal; Lt. Ed. L. H. Johannessen, USMS, Training Organization, WSA; Clinton L. Mosher, Schwabacher-Frey; and C. R. Redlich, vice president, Marine Terminals Corp. Thomas C. Ryan has recently transferred to the Club from the Port of Huntington, West Virginia.

L. Godfrey Waters and George A. Armes.

Gathered at the round table are, left to right: H. J. Wrigley, port engineer, Weyerhaeuser SS Co.; W. B. Littlefield, Harry W. Parsons Co.; J. W. Wallace, v.p. & gen. mgr., Hastings Co.; Mr. Lawrence, representing an Insurance Firm; Chas. Noland, Pat Mulvany and R. L. Strough, all of U. S. Maritime Commission construction office, Oakland; and Art Rosette, Bay Cities Asbestos Co.



Shoreside Personalities

Captain Arthur O. Brady, USNR, Commanding Officer of the U. S. Merchant Marine Cadet School, San Mateo.

Brady Promoted to Captain

The promotion of Commander Arthur O. Brady, USNR, commanding officer of the U. S. Merchant Marine Cadet School, San Mateo, California, to the rank of captain in the United States Naval Reserve was announced.

Captain Brady, a native of Methuen, Massachusetts, began his career in the merchant marine when he was 17 years of age aboard the U. S. Coast and Geodetic Survey vessel Pioneer. He graduated from the Massachusetts Nautical Academy in 1922 and served with the American Hawaiian Lines, United States Lines and Panama-Pacific Lines during his 20 odd years of sea experience as merchant marine officer, master and pilot.

Soon after World War II he was given an assignment as District Cadet-Midshipmen supervisor with the U. S. Merchant Marine Cadet Corps in San Francisco. Later he assumed the duties of assistant to the supervisor, U. S. Merchant Marine Cadet Corps, in Washington, D. C. He served in that capacity until December 4, 1944, when he took command of the Cadet Corps installations at San Mateo.

Election to Sterling Engine Board of Directors

Addison F. Vars, president of the Sterling Engine Company, announced that at the annual meeting held in the company's Buffalo offices December 27, Robert E. Dillon was elected to the board of directors.

With a broad experience in industrial and financial circles Mr. Dillon will be in a position to contribute much toward the continued success of Sterling Engine Company's postwar plans.

In addition to his directorship in the Sterling Engine Company, Mr. Dillon is also president and general manager of the Lake Erie Engineering Corporation, director of the Marine Trust Company, Air Investors, Inc. of New York City, and several other financial and manufacturing companies.

Mr. Dillon is most energetic in civic and philanthropic activities having served as vice president and director of Buffalo Chamber of Commerce and Chairman Erie County Emergency Relief Board.

Robert E. Dillon, elected to the Boord of Directors of Sterling Engine.

Officers and other directors of the Sterling Engine Company are: Spencer H. Logan, chairman of the board; Charles A. Criqui, vice chairman of the board and director; Addison F. Vars, president, general manager, treasurer and director; Hans Bohuslav, vice president-in-charge-of engineering and director; Frank G. Raichle, secretary and director.

OTHER DIRECTORS

William J. Conners, Jr., publisher of the Buffalo Courier Express, Buffalo, N. Y.; Lewis G. Harriman, president, Manufacturers & Traders Trust Company, Buffalo, N. Y.; Carroll E. Gray, Jr., chairman of the board, United Aircraft Products, Inc., Dayton, Ohio; Fred C. Rummel, president, Burr & Company, New York, N. Y.

New Appointments Made by Matson

W. J. Williams has been appointed as superintendent engineer of Matson Navigation Company, according to a recent announcement by Hugh Gallagher, vice president in charge of operations.

Mr. Williams, well known to the Pacific Coast shipping industry, has been associated with Matson since 1928. He has served in various capacities in the engine department on Matson's freight and passenger vessels and has occupied positions both in San Francisco and Honolulu in connection with ship maintenance and repair operations. During the war, Mr. Williams was general superintendent of the Maintenance Division of Matson's Construction & Repair Department.

While in Los Angeles, the importance of postwar plans of the Matson Lines was further stressed with the announcement of H. E. Pippin as assistant passenger traffic manager in charge of the Southern California area.

Pippin's career with Matson began in 1926, and during the intervening years he has assisted in the development of passenger traffic in Matson offices in New York, Chicago, San Francisco and Australia. Since 1942 he has been stationed in Los Angeles.

Matson is increasing its Los Angeles staff with a view to resumption of normal commercial shipping during 1946.

W. J. Williams, superintendent engineer Matson Navigation Co.

WHO'S WHO AFLOAT AND ASHORE

SKIPPER OF SWEDISH MOTORSHIP BIO-BIO: Captain Karl Andreason, who until the war, served as Port Captain for the Johnson Line with headquarters in San Francisco, was on the bridge of the Motorship Bio-Bio when this vessel arrived on the Pacific Coast last month.

A large group of friends welcomed the popular skipper upon his return, from Sweden. On his return to Gothenburg, Captain Andreason will leave his command to assume one of the key posts in the Operation Department of the Johnson Lines General Office.

ANOTHER RETURNS TO PEACETIME DUTIES: Howard H. Wickersham, member of the firm of W. H. Wickersham Company, steamship agents with offices in Los Angeles Harbor, has returned to his business duties after serving as Tanker Operation Officer with the Navy. At the time of his deployment he held the rank of Commander in the United States Naval Reserve.

PACIFIC WESTBOUND CONFERENCE MANAGER: The appointment of Harry Hornung as manager of the Pacific Westbound Conference, places in this important post an official, who by experience and acquaintance is especially qualified for the post.

Hornung, who rose to the rank of Colonel during this war, was in command of some of the most important troop cargo handling assignments in Australia and the Philippines during critical operations. Before the war he served for fifteen years as freight traffic manager with the N. Y. K. Line. He is regarded as being one of the outstanding marine traffic executives in the transpacific trade. Hornung's knowledge of rates, rules and practices in the Oriental trades, and his experience in ports of the Far East, will serve him well in handling problems which will arise in the affairs of the Pacific Westbound Conference.

Lieutenant Commander Ray Cox, USCG, Merchant Marine Technical Division.

LT. COMDR. RAY COX resigned from the United States Coast Guard Merchant Marine, Technical Division, to become associated with Walter Kidde & Company, Inc., as assistant manager of its Marine Division. Lt. Comdr. Cox assumed his new duties on November 1. Cox is a graduate of the U. S. Naval Academy at Annapolis, class of 1935, and upon graduation became associated with the Department of Commerce, Bureau of Marine Inspection and Navigation, as naval architect.

FOLLOWING MATSON'S FIRST-OF-THE-YEAR BOARD MEETING, William P. Roth, chairman of Matson Navigation Company, announced election of Platt Cooke of Honolulu, as a director.

Cooke is well-known in Hawaiian trade circles. He is vice president and general manager of Alexander and Baldwin Ltd. He fills a position on the Matson Directorate left vacant by the death of John Waterhouse of Alexander and Baldwin.

NOW ON THE STAFF OF ADMIRAL TISDALE in the Twelfth Naval District is Stanley "Sea" Allen, who is remembered as the first secretary of the Mariner's Club of California, and, until shortly before the war, a member of the Marine Department of Standard Oil Company of California.

After joining the Navy, Allen served in various assignments, most of the time attached to Caribbean Naval posts. He holds the rank of Commander following a recent upgrading upon his return to the States.

MAJOR EUGENE J. "BUD" JUDGE, stationed in the Hawaiian Islands with the U. S. Army, is expected to be discharged and return to San Francisco shortly, to join forces with W. R. Grace and Company. He will take charge of the passenger activities of the Johnson Line, which he handled for many years prior to entering the service.

Major Reginald V. Grady, son of Dr. Henry F. Grady, American President Line's president; is shown above being presented with the "Most Excellent Order of the British Empire" by Field Marshal Sir Harold R. L. G. Alexander. The award to Major Grady was for his outstanding service as Industry & Commerce Officer for Italy.

BREAKDOWN AT BY ALERT G-E

Careful inspection and cleaning of tanker's propulsion motor, completed in only 72 hours, forestalls salt water damage

Acting on a hunch that trouble was brewing in his propulsion motor, the tanker's chief called in a G-E marine engineer for a thorough inspection. Opening a port in the motor casing, this engineer noticed a powdery white deposit on the rotor. Salt! It could only mean that salt water with its highly corrosive effects on insulation was present in the cooling air for the motor.

The problem was double-edged—first, locate and repair the leak. Second, remove every trace of salt deposit. Time was short—but the only alternative was a potential breakdown of the motor's windings, possibly far out at sea.

Working 'round the clock for three days, G-E motor experts found and fixed the leak. Every inch of insulation was carefully cleaned and tested, the only really foolproof way to completely rid the motor of the salt. The tanker was able to sail after a seventy-two-hour tieup, half the delay that had been expected.

Catching trouble in the making

A vitally important part of G-E keep-'em-sailing service is the *prevention* of trouble. By careful routine inspection and thorough preventive maintenance of steam and electrical propulsion machinery, skilled G-E personnel can help eliminate the causes of major breakdowns.

Wherever your ships dock, they can conveniently use this service. For G-E maintains 28 fully-equipped service shops, eight of them in coastal cities. Moreover, a qualified marine superintendent is on call 24 hours a day in every major port. Should repair or replacement parts be needed, we can make immediate shipments from warehouse stocks strategically located for fast marine service.

You know that every hour you can lop off port time means greater earning power for your ships. That is why we have streamlined our entire marine service organization to give you fast reliable service that will keep your ships at sea, operating efficiently, earning dividends. Apparatus Dept., General Electric Company, Schenectady 5, N. Y.

Removing field coil from the rotor for cleaning and inspection. Skilled G-E workmen with years of specialized marine experience stand ready to help you get fast, reliable shipboard repairs and save days of unprofitable port time.

SEA PREVENTED

KEEP 'EM SAILING SERVICE

Cleaning and testing the windings on this huge propulsion motor kept a full G-E service crew busy night and day for 72 hours. In addition to fast, reliable maintenance service, ship owners can also get "off-the-shelf" delivery of urgently needed replacement parts from G.E.'s million-dollar warehouse stocks in New York and San Francisco.

Or, worn or damaged motors may be turned in under the G-E exchange plan (now covering some 30 types of marine induction motors) for immediate delivery of completely re-built motors. (Right) G-E technician checking the insulation on the collector rings of a motor with a meghometer.

GENERAL ELECTRIC

200-49

Eric L. Pedley, manager of San Francisco office of Martin & Turner.

Marine Supply Firm Enlarges in San Francisco

James S. Martin of Martin & Turner.

Martin & Turner recently moved to larger quarters, located at 134 Sacramento Street, and activities in this area will be under the management of Eric L. Pedley who has recently arrived in the United States from the China-Burma Theater of War, where he was a Lieutenant Colonel in the Army Air Forces. Mr. Pedley is well known in San Francisco and throughout the United States and abroad—where he was one of the ranking polo players prior to the war.

Martin and Turner have been actively engaged in the marine supply business in the Los Angeles Harbor for the past four years, and represent some of the larger concerns in the United States. It is the intention of the firm to broaden their scope in the San Francisco Bay area, and they are taking on additional lines in San Francisco and increasing their personnel.

Messrs. Martin, Turner, and Pedley are well known to one another as they were all partners in business in Los Angeles before the start of hostilities abroad.

Captain Lloyd E. Rogers, formerly with the Lloyd E. Rogers Company and the Crane Company and well known on the San Francisco waterfront, is in charge of sales in the Bay Area.

Captain Lloyd E. Rogers, sales manager with Martin & Turner.

Rest Centers for Merchant Seamen to Be Run by United Seamen's Service

The United Seamen's Service has taken over administrative control and continues operation of two rest centers for American merchant seamen hitherto operated jointly by the USS and the War Shipping Administration and scheduled to close the end of the year. The U. S. Public Health Service will cooperate with the USS by supplying medical attention and consultation at the centers.

The centers are located on the estates of Mrs. C. Suydam Cutting, Gladstone, N. J., and the late Darius Ogden Mills, Millbrae, Calif., and are the only two remaining in existence of seven operated by the USS and WSA during the war.

The decision to assume responsibility for operation of the two centers to meet needs on both the East and West Coasts was made by the USS Executive Committee, of which John E. Bierwirth, president of the New York Trust Company, is chairman. Operation of the centers will continue pending the determination of future programs for American merchant seamen.

Public Health Service physicians at the centers will care for seamen suffering from operational fatigue who can be restored to health so they can ship out again, as well as seamen suffering from traumatic war neuroses, including a considerable number of seamen prisoners of war, and seamen such as post-operative cases, who do not require hospital care or constant treatment or observation but who are unable ot work until after some convalesence.

The services provided in the centers will be good food, a pleasant, restful environment and planned but not regimented recreation, besides medical attendance and guidance.

The USS Executive Committee was influenced by surveys which indicated that hundreds of merchant seamen would suffer from the closing of the centers. Many of these seamen are repatriated prisoners of war.

Xzit Sales Company and Brickseal Refractory Co. entertained a large group of prominent executives of shipping lines at an Open House held at the Downtown Athletic Club, New York City. In this photo are a part of those who attended.

First row, left to right: G. W. Couch, R. H. Govan, W. S. Jackson, J. L. Callender, Victor Paul, W. Johnson, Charles LaPlante, H. P. Gibney, Sidney Pollock, A. J. Collins, Joseph Leahy, Bill Partridge.

McTaggart, W. W. Kilpatrick, W. E. Stein, W. Lindner, George Huff, Mike Doyle, Harold Baumgartner, Charles Holmgren, Lester Thomas, Henry Stuart.

SHORESIDE PERSONALITIES

New Leslie Agents

Leslie Co., Lyndhurst, N. J., manufacturers of regulators, controllers and whistles, announces the appointment of the following agents to handle marine sales and services:

Bruce Greaves Co., St. Louis, Mo., eastern Missouri and southwestern Illinois; Gulf Engineering Co., Inc., Savannah, Ga., South Atlantic Ports; Robinson Electric Co., Ltd., Vancouver, B. C., Canada, in that territory.

Presidential Appointment

President Truman nominated Rear Admiral Joseph F. Farley to be commandant of the United States Coast Guard for a four-year term. He will hold the rank of admiral.

Farley, 56, is a native of Oxford, Ohio. He has been serving as chief personnel officer for the Coast Guard.

Farley will succeed Admiral R. R. Waesche, who has been ill. Waesche commanded the Coast Guard during the war.

Westinghouse Names New Arizona Manager

W. E. Lee, formerly of Los Angeles and a sales engineer in the mining industries for the Westinghouse Electric Corporation there since early April, 1945, has been named manager of the company's Phoenix office.

Louis G. Berger, of Los Angeles, Southern California District manager, Westinghouse Electric Supply Company.

Louis G. Berger of Los Angeles, Calif., has been named Southern California district manager for the Westinghouse Electric Supply Company with headquarters there. Mr. Berger succeeds B. S. Manuel, vice-president of the supply firm. Mr. Manuel will continue as vice-president, with overall responsibility for operation of the southern California, northern California and north Pacific districts of the company. A native of Michigan, Mr. Berger joined the Illinois Electric Company at Los Angeles in 1920, and when this organization was dissolved, in 1927, he transferred to the Westinghouse Electric Supply Company there. He was appointed assistant district manager in February, 1945.

Gelhaus Returns

Henry F. Gelhaus has returned to San Francisco after approximately five years with the Todd Shipyards Corporation, as assistant general manager of their Brooklyn Yard.

He is now Pacific Coast sales manager for the company with headquarters at 485 California Street, San Francisco.

He is well known on the Pacific Coast and for many years was marine superintendent for the Swayne & Hoyt Company.

S. F. Office of Roto Division

C. L. Gould has been placed in charge of the new San Francisco office of the Roto Division of Elliott Company, manufacturers of tube cleaners. The office is located at 526 Folsom Street. Gould, who has been with the company for over ten years, was previously in charge of the New Jersey district.

HERE IT IS!

The

"Mariners Pathfinder"

Raytheon's Radar

FOR AMERICA'S MERCHANT SHIPS

Designed by the SOLE MAKERS of the SG and SO Radar on America's Fighting Ships!

AT LAST we can show you a picture of the new gear! Fuller details will follow.

But even without the picture *you know what you are getting* when you specify Raytheon Radar. You know you are getting *the same basic radar equipment* used by every Navy combat ship from destroyer to battlewagon, and even down to landing craft. You are getting a simplified, compact version of the famous SG or SO radar built for the Navy by Raytheon, and now built in commercial form for you.

Remember that Raytheon was the Navy's chief supplier of *surface-search* radar, the one type of radar that a merchant ship needs. Remember, too, that factory-trained technicians will be available for service in nearly every major seaport. Remember *the name that means most* in surface-search radar!

Watch for further announcements. Meantime, count on Raytheon Radar to safeguard your ships and speed up operating schedules. Early delivery and installation can be expected. Inquire. Write or wire to Marine Department, 107 Foundry Ave., Waltham 54, Mass.

The INDICATOR can be mounted on the bridge—on deck, bulkhead, or overhead. Note that the head is rotatable vertically and horizontally through 45°... *adjustable* for greatest comfort and convenience!

RAYTHEON

RAYTHEON MANUFACTURING COMPANY,
ELECTRONIC EQUIPMENT DIVISION

Excellence in Electronics

Shoreside Personalities

N. A. Moore, since 1936 assistant district manager at San Francisco for the American-Hawaiian Steamship Company, has been named to succeed **Fred N. Mills** as district manager at Portland for the company. The appointment took effect February 1.

Mills, who has served American-Hawaiian for thirty-eight years and who has been Portland manager since 1927, has announced his retirement. During his many years in Portland, Mills has been active in various steamship groups. He has served on many occasions as president of the Portland Merchants' Exchange and is now acting as vice president of the Waterfront Employers' Association. He and Mrs. Mills plan to spend their time in Oregon and California.

David Shipley, new production manager, Rodpak Manufacturing Co.

David Shipley, New Rodpak Production Manager

Rodpak Manufacturing Company, makers of Rodpak floating seal metallic packing, announces the appointment of David G. Shipley as production manager for their San Francisco plant. Shipley comes to Rodpak from Bethlehem Steel Company, where he held the position of assistant superintendent of the Submarine Repair Base.

WSA Appointment

Appointment of George E. Talmadge, Jr., as special assistant to Deputy War Shipping Administrator, Captain Granville Conway, was announced by the WSA.

Mr. Talmadge will be in charge of the development and coordination of WSA programs aimed at the resumption of private ownership and management of vessels operating in the domestic trade.

From 1940 until 1944 he was Director of the Bureau of Water Carriers for the Interstate Commerce Commission. During that period he worked with various war agencies—Lend-Lease Administration, WSA, and Office of Defense Transportation. Recently he has been transportation engineer and general sales representative of the Higgins Industries, Inc., New Orleans, La. Prior to his government service, Mr. Talmadge had been engaged in steamship work over a period of 20 years.

Naval Architect-Marine Engineer Opens Offices

Karl French, naval architect and marine engineer recently announced the opening of offices at 286 West Seventh Street, San Pedro, California.

Enlarges Quarters

To keep pace with rapidly expanding business, the George E. Swett & Co., engineers, have moved to larger quarters at 256 Mission Street, San Francisco 5, California.

San Francisco will be the principal West Coast port, according to George E. Swett, manager of the firm, and their complete organization of engineers, installation and service crews is available for marine refrigeration and other specialized marine products.

Penn Instrument Acquires Cochrane Meter Line

Penn Industrial Instrument Corporation of Philadelphia has purchased the Flow Meter Division of Cochrane Corporation of Philadelphia. The firm is headed by William C. Bennett, president and general manager, with William Melas, vice president and chief engineer, and Kenneth C. Markley, vice president and works manager.

Penn will manufacture the present line of Cochrane Flow Meters exclusively for The Hays Corporation, who will market them under the name Hays-Cochrane Meters.

San Francisco Marine Exchange

President's Report

Roy C. Ward, Cosgrove & Co., retiring president of the Marine Exchange.

Since the inception of the present form of the Marine Exchange in March 1938, as an independent, non-profit association, the Exchange has increased its services to its members; tripled its membership, and assumed new responsibilities as a ship-reporting agency to Maritime Commission representatives of the San Francisco Bay Area. The finances and income of the Exchange seem to be adequate to carry it through the reconversion period.

It can now be told that, to our knowledge, the Marine Exchange of San Francisco is the only one of all similar privately-operated agencies in this country that continued its ship-reporting activities during the war. This was made possible not only by the well merited reputation of the Exchange Staff, but particularly by the foresight of Commodore Milton S. Davis, director of the Port of this, the Twelfth Naval District, who had jurisdiction over local harbor activities from the time of Pearl Harbor and for a continuing major period of the war.

H. H. Pierson, new president of the Marine Exchange.

The Marine Exchange operated during the period of hostilities under the guidance and control of the Port Director's office of the Navy. Information on ship movements was only given to those approved by that office. Under this arrangement, private telephone lines were installed to the Army's Port of Embarkation, to naval and military intelligence offices. The Exchange switchboard provided private interchange of information to all government departments concerned with the local activities of shipping.

The trust placed in the Exchange and particularly its members was well merited. During the hectic war period, when the Bay Area handled far in excess of the tonnage of vessels and cargo ever thought possible, no misuse of information has been reported. For this the integrity and watchfulness of the members is to be greatly commended.

Now let me say a few words regarding the activities of the Exchange in fields other than ship-reporting. Necessarily, an association such as this, of steamship companies, shipyards, marine underwriters, terminal operators, ship chandlers, manufacturers' agents, jobbers and wholesalers of marine equipment machinery and supplies, ship service organizations, banks handling marine organization funds, exporters, importers, shippers in general, forwarding agents, customs and ships' brokers and others, is frequently asked to take a hand in public matters.

Requests for help came from individuals and companies who preferred dealing with government and its agencies through an association rather than in their own name, in order to secure changes in legislation and regulations, whether in effect or proposed.

In this respect, we have learned that our weight of numbers and because the Exchange can speak for the maritime industry of the Bay Area, that as a maritime association we do receive genuine consideration.

In the early part of 1941, for example, a committee of the Exchange secured a change it requested in a ruling of the Bureau of Customs of the Treasury Department placing a heavy fine on steamship companies whose vessels discharged at San Francisco merchandise which a vessel's manifest indicated would be discharged at Los Angeles.

Another committee of the Exchange was successful in the latter part of 1940 in securing amendments to proposed regulations on inflammables and explosives, that would have placed a severe handicap on the cargo movement of the port.

Again in the early part of 1941, a committee of the Exchange was helpful in defeating the adoption by the State Legislature of laws that would have adversely and seriously affected the sale of small craft.

These are a few examples of what an association can do. They have also proved, and very definitely, that the San Francisco Bay Area labors under an onerous handicap, due to its separation into twelve politically divided counties, as compared with Los Angeles County. To assist in overcoming this handicap, the Exchange proposed the formation of a Bay Area Maritime Committee. The Junior Chambers of Commerce of the Bay Area took up the suggestion. The resulting Bay Area Maritime Committee, with well selected representatives of the twelve counties, is an effective group.

San Francisco County is represented by Supervisor Chester MacPhee, Port Manager Neil Laidlaw, Don Fazackerley, executive vice president of the San Francisco Junior Chamber of Commerce and our own secretary manager. The Sacramento delegation, for instance, includes Charles Deterding, the county manager, Luke Conrad, a Sacramento County supervisor and William G. Stone, manager of the Sacramento Chamber's transportation and industrial committee.

By means of this committee, it is possible to secure support in Sacramento and Washington, D. C., similar to, but of course not on a par, to that available to Los Angeles County.

I come now to present and future activities of your Marine Exchange. We have supported resumption of intercoastal and coastwise operations by the War Shipping Administration. While government operation is not desirable, we are convinced, along with the operators, that only in this way could costs of running ships today be arrived at.

The WSA has, as you know, reestablished intercoastal service, with the former operators acting as its agents. The resumption of coastwise service still remains to be put into effect. To push this along, we have asked for support of all Chambers of Commerce in ports along the coast. Subsequently the Interstate Commerce Commission ruled that the rail port-to-port rates must include the specified differential over and above the vessel rates. This is a step in the right direction which the coastwise operators have sought for a long time.

The next step, of course, is private operation of both intercoastal and coastwise services. This depends on the experience developed by WSA operations.

Let me conclude by saying this: During the past years, the port of San Francisco, "serene and indifferent to fate" pursued the even tenor of its ways. Then the war came along and this Bay became the principal staging area in the conflict with Japan. We found it necessary not only to raise our sights, we threw the sights away. This area became the world's principal shipbuilding plant. We not only shipped most of the men and supplies to the Pacific combat area, we are handling most of the returning troops now. Why—because

San Francisco Marine Exchange

we have more facilities than any port on the coast.

There is a lesson in that for all of us.

In the past, our shipping in San Francisco declined because perhaps, among other reasons, we were not organized as an area to stop that decline. We have been indifferent. No matter what the explanation is for the past, we must work together for the future. We have all the means to make this a much greater port in peace than it ever was in war. To this end, the Marine Exchange is preparing to meet its responsibilities in the days to come.

The offices of the Marine Exchange, with your support, look for an eventful 1946.

Following the recent election, the directors to hold office are:

Leo P. Bailey, Balfour, Guthrie & Co., Ltd.; W. J. Bush, American President Lines, Ltd.; J. Harding Jensen, Matson Navigation Co.; A. E. Kihn, Standard Oil Company of California; Joseph A. Lunny, (Pope & Talbot), McCormick S. S. Co. Div.; Howard N. Middleton, War Shipping Administration; W. F. Minehan, Bank of America, N. T. & S. A.; Joseph A. Moore, Jr., Moore Dry Dock Company; John Parker, American Marine Paint Company; H. H. Pierson, De La Rama S. S. Co., Inc.; Roy C. Ward, Cosgrove & Company.

The directors chose the following officers:

H. H. Pierson, president; John Parker, first vice president; A. E. Kihn, second vice president; Joseph A. Moore, Jr., third vice president; J. Harding Jensen, treasurer.

Interocean's Operating Managers

Howard G. Beadle, operating manager, San Francisco. Mr. Beadle originally joined the Interocean family in 1937 and went into the Navy in March, 1941. Mr. Beadle will handle the operation of all vessels in the San Francisco Bay District including Intercoastal, European and Oriental, coming under that jurisdiction.

Homer B. Harris, operating manager, Los Angeles Harbor. Mr. Harris joined the Interocean family in 1934, and became experienced in the work of practically all departments until outbreak of the war when he joined the Army, gaining further shipping experience along the Pacific Coast and in the Philippines.

R. G. Jubitz, Jr., traffic manager, Intercoastal service, Portland, Oregon. Mr. Jubitz originally joined Interocean in 1938, as assistant in the Portland office. At the beginning of the war he went into the Navy and was recently discharged after an eventful career, including service as commander of Navy vessels carrying refugees from the Orient to this country.

J. G. Pacey, operating manager, Seattle, Washington. Mr. Pacey joined the firm last year to assist Mr. Alflee, district manager, Seattle, in the handling of War Shipping Administration vessels in the Puget Sound territory. In recognition of his good services he has been promoted to the position of operating manager.

Shoreside Personalities

JULIUS BAYARD, in charge of the marine service activities of the Foster-Wheeler Company on the Pacific Coast, is now located in the San Francisco office at 206 Sansome Street.

Previous to joining the company's organization in 1942, he learned his marine engineering fundamentals in Charleston, S. C., later sailing in the Gulf Oil Corporation vessels. He advanced to chief engineer with a steam and diesel license.

From 1942 to 1944 Bayard was stationed in the Pacific Northwest in connection with the installations on board the C. V. E. vessels built in Tacoma and Vancouver, Washington. In 1945 he became civilian technician for the company, attached to the U. S. Navy at Guam.

Joseph L. Turner, director of Industrial Relations, Columbia Steel Company, San Francisco.

The appointment of Joseph L. Turner to the position of Director of Industrial Relations of Columbia Steel Company, a U. S. Steel Corporaton subsidiary, was announced by Wlliam A. Ross, president. Turner, who has been in the steel business since 1928, succeeds Henry T. Lintott, resigned.

Turner started his career with Lukens Steel Company in Coatsville, Pennsylvania. After eight years with this firm, he joined Wheeling Steel Corporation as assistant to general manager of the Portsmouth, Ohio, Works. Four years later he was promoted chief industrial engineer at Wheeling, West Virginia, which position he held until his new post with Columbia Steel Company.

J. Edward Meyer, Jr., who, while Lieutenant Colonel in the United States Army Transportation Corps, established "a record of daily discharge per ship unequaled anywhere in the world," has been appointed assistant operating manager of Grace Line, Inc., it has been announced by officials of the line.

Beginning his steamship career as an ordinary seaman with Grace Line in 1934, Mr. Meyer has been subsequently employed in various capacities in pier and traffic operations. In his present capacity he replaces D. P. Darling, who was recently promoted to assistant manager of Panama Agencies Co., a Grace subsidiary in Cristobal, C. Z.

After serving in the United States Navy as a Lieutenant, Stanley G. Coppel has returned to the Weyerhaeuser Steamship Company as assistant manager of the San Francisco office.

Pennington, Vice President Of N. F. A. S.

Gearing itself to meet the many problems which will confront the American Merchant Marine upon its resumption of private, commercial operations after March 2, National Federation of American Shipping announced the elevation of its secretary-treasurer, **Maitland S. Pennington,** to the position of vice president.

Almon E. Roth, president, in announcing the promotion, stated that Pennington was elevated to the post by the Board of Directors of the Federation.

Roth also announced that the Board had elected Mrs. Marjorie Nave to the position of secretary and assistant treasurer.

Pennington, 38, only recently returned from Copenhagen, Denmark, where he represented American shipowners at the Preparatory Technical Maritime Conference of the International Labor Office.

The conference made recommendations for international and minimum standards on wages, hours of work aboard ship, training and promotion at sea and recognition of seafarers' organizations which are to be presented to the International Labor Office Conference to be held in Seattle, Washington, the end of May and beginning of June, this year.

The Briggs Filtration, Clarifier Companies Merge

The engineering and manufacturing enterprise founded in 1933 by Chase Donaldson and S. W. Briggs as the Briggs Clarifier Company took its final peacetime form on December 1, when the business was acquired by the Briggs Filtration Company, a Maryland corporation. The officers of the new company, all of whom served with the old company, are Chase Donaldson, president; S. W. Briggs, vice president; R. C. Zschiegner, treasurer; W. E. Furey, secretary-counsel; Cecil Hopkins, assistant secretary. The directors are Chase Donaldson, president; S. W. Briggs, vice-president; Richard P. Dunn, partner, Auchincloss, Parker & Redpath; Bradley J. Gaylord, vice president, the Pennroad Corporation, Wilmington, Delaware; Clark W. McKnight, Wilmington, Delaware.

The Briggs Filtration Company, which owns all patents, processes and trade names, will continue to design and manufacture the extensive line of oil filters which won the Army-Navy "E" three times. The famous Briggs Clarifier, which has won general acceptance in the diesel, automotive, maritime, railroad and aviation fields, has been further perfected by design simplification and the development of additional types of refills to meet every oil filtration need with the greatest economy.

Harry J. Price To Edit New Travel Magazine

Harry J. Price, formerly director of public relations, advertising and publicity of the Todd Shipyards Corporation, has been named Executive Editor of The Smart Traveler, a new independent national travel magazine, the first issue of which will appear April 10. The Smart Traveler will have a guaranteed circulation of 100,000 copies and a print order of 150,000, which is to be increased as printing facilities become available.

Mr. Price, a former newspaper man and foreign correspondent, is a vice president of the Overseas Press Club. He is no stranger to travel at home or abroad and his work in the travel industry is well known to all transportation executives and travel agents dating back to 1931 when his Line on Liners and Eight Bells or Thereabouts columns won him wide distinction as the Brooklyn Eagle's travel editor.

New Southern California Corp.

Formation of a new corporation, the Dauby Equipment Company of Santa Monica, California, was announced in the December issue of the Pacific Marine Review. Sales and advertising will be headed by O. J. Gilman, recently connected with the National Screw and Manufacturing

O. J. Gilman, sales and advertising manager, Dauby Equipment Company.

Company of Cleveland, Ohio, in similar capacity. Mr. Gilman's past record includes technical engineering and sales in the marine and aircraft hydraulic control field.

The remote controls manufactured by this firm are trade-named BOS'N'S MATE and include throttle, power clutch and power steering controls of the non-automatic, direct hydraulic type.

Geddco Record in War Earns Navy Award

The record of General Engineering and Drydock Company, of San Francisco and Alameda, in sending back to sea during the war over 3000 repaired and converted vessels has earned the Navy's Certificate of Achievement, the Company has been notified by Lieutenant Frederick W. Wile, Jr., USNR, Acting Chief, Industrial Incentive Division.

In a letter to George A. Armes, president of General Engineering, Lieutenant Wiles said:

"It is my distinct pleasure to advise you that the Navy's Certificate of Achievement has been awarded to your organization.

"This Certificate, which is being sent you under separate cover, signalizes the Navy's recognition of the splendid effort put forth by the men and women of your organization in support of the war production program."

Lieutenant Wile added that he hoped the Navy's "sincere appreciation" would be communicated to all of GEDDCO workers.

WSA Awards Certificate Of Appreciation

Clyde Williamson, San Francisco manager for Hagan Corporation, Pittsburgh combustion and chemical engineers, has been presented with a Certificate of Appreciation from the War Shipping Administration for help given in the cadet-midshipman training program during the war. Mr. Williamson is the first Pacific Coast man, and one of the few in the nation, to be given this form of recognition by the WSA. The presentation was made by Lt. Com. E. G. McDonald, district cadet-midshipman supervisor for San Francisco.

Nine of the company's port offices assisted the WSA by teaching and providing combustion and chemical data for the use of men being trained to operate the vast wartime fleet of merchant marine vessels.

Business Tour of Orient

Colonel Oliver Vickery, of Owesen & Company, marine electric supply house of San Francisco, will soon leave by American President liner on a business tour of Oriental ports. He will establish a branch office in Manila to take care of the company's expanding trade in that territory, and will return to San Francisco some time in May.

Colonel Oliver Vickery

Manager of Marine Transportation at Socony-Vacuum

The retirement of Charles H. Kunze and the appointment of Frederic R. Pratt to succeed him as general manager of the Marine Transportation Department were announced by the Socony-Vacuum Oil Company, Inc.

Mr. Kunze started with the company in 1904 as office boy and served in various capacities throughout the years. On December 1, 1941, he was appointed general manager of the Marine Transportation Department.

Mr. Pratt recently returned to Socony after four years in the Coast Guard. He entered the Marine Transportation Department in 1931 and in 1940 was transferred to the Distribution Department until he entered the service.

Opening Law Offices

William Radner, recently general counsel for the War Shipping Administration, and from 1939-1942 officer of Matson Navigation Company, announceves the opening of law offices in the Hill Building, Washington, D. C.

Resumption of Upgrading Training

Resumption of upgrade training for Merchant Seamen by the U. S. Maritime Service, suspended in December as a step toward overcoming the shortage of crews to man ships bringing troops home and carrying relief supplies aboard, was announced January 16 by the War Shipping Administration.

Because of continuing shortages, for the time being, officers will not be accepted for upgrade training. However, WSA will resume acceptance of applications from unlicensed personnel in deck, engine and stewards departments for admittance to Maritime Service upgrade training schools. As soon as shortages are overcome, officer upgrading will be resumed.

To be eligible, seamen must apply for such training within one week of discharge from a WSA vessel. The WSA through the U. S. Maritime Service has operated upgrade schools and examining systems during the war, and since, to help provide sufficient experienced seamen for higher ratings and officer ranks needed by the rapidly expanding Merchant Marine.

The ports at which the U. S. Maritime Service maintains upgrade schools are New York, San Francisco, Los Angeles, Wilmington, California; Portland, Oregon; Seattle, Boston and New Orleans.

Waterfront Employers Association News

The dual post of Secretary and Treasurer of the Waterfront Employers Association, vacated by the untimely death of Abraham Boyd on December 31, is now being temporarily filled by Kenneth F. Saysette as acting treasurer, and James A. Robertson as interim secretary, it was announced by Frank P. Foisie, president.

Joseph H. Travers, former Colonel in the U. S. Army, has resumed his old position as assistant manager of the Accident Prevention Bureau of the Waterfront Employers Association, Pacific Coast.

Lt. Col. John W. Hubbell, Assistant to the President of Simmons Company, in charge of merchandising and advertising.

Hubbell Returns to Simmons Company

Lt. Col. John W. Hubbell, recently released from the Army, has returned to the Simmons Company, according to an announcement by G. D. Wrightson, vice president in charge of sales. Colonel Hubbell, formerly promotional and sales advertising manager, has been appointed to a new position in the company, Assistant to the President, in which he will direct all merchandising and advertising.

New President of C. H. Wheeler Mfg. Co.

The executive officers of the C. H. Wheeler Mfg. Co., Philadelphia, Pa., manufacturers of steam condensers, steam jet air ejectors, heat exchangers, water cooling towers and deck machinery (hoists, windlasses, etc.) now consist of C. M. Brown, chairman of the board; P. S. Lyon, president, and general manager, F. L. Yetter, vice president; L. A. Droescher, vice president; J. J. Bolton, Jr., vice president, and J. S. Gabel, secretary and treasurer.

Mr. Lyon is a newcomer to the company, but he is well-known in power plant and general industrial plant circles. Until recently, he was president and general manager of the Cochrane Corporation of Philadelphia, and resigned when the company ownership changed. He was with Cochrane Corporation and the Turbine Equipment Co. of New York (Cochrane's exclusive sales representative) for a total of about 26 years, during which time he perfected and marketed the Cochrane mechanical Flow Meter. Further, he developed on a new principle, engineered and sold Cochrane's first successful deaerators for boiler water. He also was chief engineer for the Hall Electric Heating Co. of Philadelphia, and later headed the Engineering Section of the Air Conditioning Dept. of the General Electric Co. in New York City.

P. S. Lyon, President of C. H. Wheeler Mfg. Co.

Jorgensen Expands Facilities

Earle M. Jorgensen Co., steel distributors, are practically doubling their warehousing facilities in Oakland by building an additional warehouse of all-steel construction 70 feet wide by 526 feet long on the property adjoining their present warehouse, and then are enlarging their office to about three times its present size. Construction is now under way and will be rushed to completion.

Equipment for the new warehouse and additional equipment for the existing warehouse, which is also being extensively improved, will include two 5-ton overhead cranes and a 24-inch capacity friction saw for cutting structural shapes. Burning equipment will consist of 70 feet of burning tables, two 150-lb. generators for generating acetylene gas and a Cascade unit for oxygen, one 4-torch and one 2-torch shape cutting machines for cutting circles, rings, sketches, etc. In addition, two portable cutting machines for straight line cutting will be used. All torches will be equipped to cut plate up to 10 inches thick with special attachments available for heavier sections. Additional delivery equipment will include a 5-ton truck and trailer with a 30-foot bed.

The Jorgensen Company plans to carry one of the most diversified lines of steel available anywhere. Stocks will include carbon, alloy, stainless, tool and specialty steels in the form of bars, billets, plates, sheets, strip and structurals.

Clarence J. Hunter, president and general manager of The Dampney Company of America.

On Tour to Coast

C. J. Hunter, chairman of the board and technical director of the Dampney Company of America, manufacturers of Apexior for stationary boilers, locomotives and steamships, toured the Pacific Coast territory on company business during January.

Joins Research Corporation

Election of Howard G. Vesper as president of California Research Corporation, Standard of California's research subsidiary, was announced by R. G. Follis, president of Standard.

Vesper succeeds Ralph A. Halloran, who is retiring after 26 years spent as head of Standard's research activities, during which time he has been credited with directing many notable developments in petroleum processes.

Both Vesper and Halloran played important parts in Standard of California's war work, Vesper in handling allocations of all bulk products, except aviation gasoline, for essential civilian use and military requirements and Halloran in directing a research program devoted 95 per cent to government and military projects.

SELECTION OF SAFETY AND RELIEF valves simplified by new Catalog No. 45, just issued by the Farris Engineering Company. Many new valve designs and improvements in old designs are included.

A "ready-reference pictorial index chart" shows line drawings of all the basic Farris valve types. With this chart a valve user can pick out the valve he needs without having to thumb through a whole catalog. Directly opposite the pictorial index chart is a detailed index showing what the valve can be used for and where to find its specifications in the catalog.

A condensed bulletin and price-sheet is contained in a supplement (No. 45A) to the Farris catalog. In this supplement a user or jobber can readily find the net price (accompanied by an illustration) of any valve without discount computations, as all prices are net on the price-sheet.

Eccles & Davies Machinery Co., Inc., Los Angeles, California, has issued a 16-page, two-color booklet "Edco Electrodes" which describes in detail the physical and chemical properties of these time-tested phosphor bronze electric welding rods. It gives uses and techniques for welding copper, bronze, cast iron, steel and their alloys; and contains a polarity table and directions for best welding results. The information will prove valuable to every welder and shop man.

"Industrial Logistics," a 12-page, illustrated booklet issued by The Elwell-Parker Electric Co., Cleveland. Subtitled "A Survey for Management," the booklet explains how a planned system of materials transportation reduces costs in procurement, production and distribution of goods. Outstanding examples of economics are cited, such as a reduction of $20.65 per car in unloading sheet metal, $41.00 per car in unloading bagged materials; a saving of $64.00 a day through utilizing full warehouse capacity.

Auxiliary booklets entitled "Logistics of Boxes," "Logistics of Barrels," "Logistics of Bags" and "Logistics of Bales" also have been prepared.

Copies of any or all of these booklets may be obtained by addressing Pacific Marine Review.

Hot Off the Press

The Meehanite Research Institute, New Rochelle, N. Y., has published a bulletin known as DM-345 which contains design data, including an analysis of stress-strain diagrams. Other engineering applications indicating strength and toughness are also described.

Deaeration: A restatement of the science of deaeration and its effectiveness in controlling corrosion is treated in a 20-page booklet just issued by the Elliott Company, Jeannette, Pa., manufacturers of power plant equipment.

Fully illustrated with charts and photographs, the booklet describes corrosion in general and the part which deaeration plays in checking it. Included in the text is a table showing the derivation of the pH. factor and graphs indicating the effect of pH. on the rate of corrosion, the solubility of oxygen and carbon dioxide in water at various temperatures, and the solubility of the oxygen component of air in distilled water at various temperatures and pressures.

Wide Range Oil Burner: Peabody Engineering Corporation, of New York, has issued a new bulletin, No. 109, describing the Peabody CD (constant differential) wide range oil burning system. It explains how the system achieves efficient combustion over a range in capacity as great as 50 to 1, controlling any number of Peabody burners.

Pocket Library of Engineering Data: For all industrial users of screw and other fasteners the Manufacturers Screw Products Company, manufacturers of fasteners, has printed a pocket size Library of Engineering Data on four vari-colored cards enclosed in a durable handy pocket envelope.

YOURS FOR THE ASKING!

The manufacturers named in this HOT OFF THE PRESS department will gladly furnish, without obligation to you, copies of the trade literature reviewed in these pages. For quick service, please use this coupon.

Book Reviews

The Practical Design of Welded Steel Structures

This publication, which is bound in cloth and sells for $1.00 per copy, can be be obtained from the American Welding Society, 33 West 39th Street, New York 18, N. Y.

This book contains information of value to designers, engineers and fabricators who use welded construction. The text explains general and detail design considerations for simple welded joints and connections, and their application to typical structural members. Beam connections are fully treated and considered in the light of continuous structures, and a brief section deals with rigid frames. A useful feature of the book is the numerous charts to facilitate the design of welded joints and structural members. These charts are so arranged as to be applicable for any specified unit working stress.

Also included in the book are brief, yet adequate, discussions of the various welding processes, specifications for electrodes, types of welds, welding positions, qualification tests and inspection. The subject of weld geometry and stress concentration is treated at some length. Temperature effects, both physical and metallurgical, have received extended attention, and one section is devoted to the codes of the American Welding Society, which have been widely adopted for most welded construction and form the basis for the numerous charts and tables. The growing importance of fatigue in many types of structures is covered by another section dealing with this topic.

CARGO DEADWEIGHT DISTRIBUTION by Martin Heuvelmans, ninety pages 5″ x 7″ bound in blue buckram with numerous diagrams and illustrations. It is published by Cornell Maritime Press, price $1.50 net.

This is a very timely treatise on a most important stevedoring specialty of how to load all sorts of general cargo into the cargo holds and 'tween decks of a modern steamer and maintain her stability, trim and balance. The fundamental principals are comprehensively covered and adequately indexed.

This small volume should be of great value to all who have any interest in the loading of ships. The author has superintended commercial stowage of cargo in ships for his entire working career.

HOW TO CUT CAST IRON: The Technical Service Department of National Cylinder Gas Co., Chicago, Ill., has just issued an illustrated circular, N-606, completely covering the "how to" on the cutting of cast iron with the oxy-acetylene flame. For many years cast iron cutting was considered almost impossible, but now with proper apparatus and technique the job can be done both successfully and economically.

Included is discussion of proper types of equipment, preheating conditions, cutting positions, need of adequate protective clothing, proper oxygen and acetylene pressures.

RIPPLE ROCK

(Continued from page 151)

Work is now suspended until the spring of 1946.

In the meantime, Ripple Rock, one of Nature's most cunningly arranged death traps for ships, still remains in place just as it did on that eventful day in 1792 when Captain Vancouver sailed through Seymour Narrows and noted its turbulent waters in his log.

Ripple Rock, dangerously crouching, still lurks—the ancient menace it has always been. In the slang phrase of the day, it cries to all mariners: "I'll be seein' you!"

DECK-EDGE ELEVATORS

(Continued from page 156)

with a tremendous force that must be absorbed without injury.

For this deck-edge elevator a radically different type of hydraulic drive was created. Electric motors pump oil continuously into a reservoir at high pressure. To make a lift, this oil is admitted to a ram, which is a cylinder and piston some two feet in diameter and 14 feet long. The outward movement of the piston is translated by steel ropes and sheaves to vertical movement of the platform with its load. For the downward trip, the valve to the reservoir system is opened and the energy of the platform and load is absorbed by the hydraulic system. This not only provides means for braking the load, but returns to the system about one-fourth of the energy required for the next lift. Use of hydraulic mechanism provides an energy storage and partial recovery system by which the peak load on the aircraft's electrical plant is reduced by nearly three-fourths.

The new hydraulic system has an incidental but important advantage over the hydraulic plunger systems heretofore used aboard ship. The hydraulic ram nestles horizontally just inside the hull, whereas previous elevators have required two vertical rams rising through the interior of the hangar deck. Hence they form serious obstacles to the handling of stowed planes.

Numerous safety features are built into the elevator. Should the steel hoisting ropes be shot away, the platform is gripped tightly by a spring mechanism at the guide rails to prevent a load from being dumped into the sea. Ordinarily the elevator is controlled electrically by an operator at the flight deck level, but in the event of any electrical failure the elevator valves can be operated manually. All of the aircraft carriers of the Essex class are provided with Westinghouse deck-edge elevators amidships. The performance in battle has been wholly satisfactory, so much so that many features of the hydraulic system are being applied to the conventional airplane elevators in the bow and stern of the carriers.

MARCH 1946

MODERN VERSION OF THE Rope Trick

During four long years of war, the mills of the Tubbs Cordage Company were forced to learn many rope "tricks." How to "stretch" each pound of precious fiber to meet the vital needs of our armed forces. How to adapt substitute fiber so that non-military users might have some rope to meet the needs of industry.

With the war over, there is still a critical shortage of Manila fiber which means that you must still wait for your Manila rope. No rope "trick" can overcome this situation.

When you once more see the famous EXTRA SUPERIOR MANILA trademark, you will know that the top grade of selected Manila fiber has been used in its construction to assure you a rope of utmost dependability.

Pacific MARINE REVIEW

An American Shipowner's Nightmare

Not the least of the worries of the American shipowner is the great number and complexity of Federal Government departments, bureaus, divisions and agencies with which he has to deal in order to conduct his business in a legal and customary manner.

One of the large American steamship owning firms recently prepared a large chart showing all of these agencies of the Government and illustrating the complexities of American marine transportation methods.

Briefly stated, this chart shows that there are in the Legislative Branch eight committees of the House and eight committees of the Senate; in the Judicial Branch five federal courts; in the departments sixty-five divisions or bureaus; three divisions in the Executive Office of the President; forty-two in Independent Bureaus and agencies; three in the Federal Security Agency and in the Security Exchange Commission, the General Accounting Office, the Employees' Compensation Commission and the National Board of Investigation and Research. This adds up to 140 Government contacts affecting the business of the ship. Then there is the American Bureau of Shipping, a private corporation, that is in some of its functions, notably "Load Line," a Government agency. In addition there are seven International bureaus or agencies.

In some of these contacts there is no difficulty, and to the well-regulated and smooth running offices of our large ship operating firms these are merely routine matters. But in an increasingly large number of the contacts with the Independent Bureaus and Agencies there is much irritation and delay caused by the inevitable red tape of civil service and the "stuffed shirt" attitude of officials. Several of the Agencies have the power of life or death over the American ship owning business.

The American ship owner is therefore in the same position as a man undergoing torture from a cage of spikes. Whichever way he moves he is certain to run afoul of the sharp point of some Government regulation. If he howls loudly enough that point is withdrawn but the act of withdrawal brings up another point at some other location on the walls of the cage, while ranged round the outside are several wicked-looking individuals with long rapiers to administer the coup de grace should the ship owner too persistently avoid the pin pricks of the spikes.

Under such circumstances it is indeed wonderful that there is any privately owned American Merchant Marine. The cure for this is within the power of the United States Maritime Commission and Congress and would be very simple were it not for entrenched civil service and bureaucracy at Washington.

> The Maritime Commission should make a comprehensive study of American Maritime Law and codify that law into a simple body of legislation covering modern marine transportation.
>
> The Maritime Commission should make a comprehensive study and investigation of the various bureaus and agencies having jurisdiction over American shipping and should recommend to Congress legislation eliminating all overlapping jurisdiction, and so far as possible consolidating all maritime jurisdictional functions under one bureau or agency, preferably the Maritime Commission.

The U. S. M. C. is instructed by law to investigate all matters relating to American shipping. Therefore, Congress should see to it that the U. S. M. C. does a thorough job of investigating and recommending and then Congress should pass the necessary legislation to make the recommendations effective.

INSIDE STORY

NEW PACIFIC VESSELS FOR AMERICAN PRESIDENT LINES

INTERIORS FORETELL DESIGN TREND OF FUTURE LINERS

By Jack Heaney

Special to Pacific Marine Review

New York, March 1, 1946. The first public look inside new Pacific passenger liners will come this year when the S.S. Presidents Wilson and Cleveland are commissioned. Into the interior design of these three-class vessels has gone the outpouring of four years' war-bound ideas. And although all of a designer's accumulated thought could not be contained in the space of one vessel, the P2-SE2-R3's indicate the trend which future marine design may follow.

Already sample staterooms, built by the joiner contractor, Aetna Marine Corporation, reveal the luxury and comfortable convenience which travelers may expect to enjoy in their quarters on these ships. With very few exceptions, cabin class staterooms are located at the ship's side. They vary in size and passenger capacity, but the average room with its generously proportioned private bath and extensive wardrobe and trunk space is equipped for three people. Through careful design and arrangement of furniture, the atmosphere of an intimate sitting room or lounge is created, suiting the room to daytime living. Beneath one or two softly draped airports, unified as one large window by a venetian blind, sits a sofa bed. It is upholstered in an original pin-stripe mohair and has the dimensions and appearance of a regular sofa. The existence of wall-flush upper and lower berths opposite is barely indicated by their outlines on the wall. At night passengers put the modern love of button-pushing to use—berths glide from their vertical, stowed position and with further digital pressure on another disk, the back of the sofa bed

Below: **TOURIST STATEROOM DAY—**

Above: **MARINE VERANDA**

slips casually down to rest on the seat. Thus, quickly and easily, the room is transformed into a bedroom beds made up and ready for use without depending on help from a steward.

In the evolution of planning the staterooms, their furniture and other facilities, the interior design section of George G. Sharp has "aimed to please" the passenger whether his desire of the hour be to sleep thoroughly on a luxurious mattress of foam neoprene-rubber, or to entertain from a comfortable lounge chair upholstered in the same resilient material. If he likes to read late into the night, without disturbing others, he may flick off the end table lamp, turn on a light in the serrated glass cylinder which forms the lamp's base and direct light to his book only. And speaking of lighting: a space-saving floor lamp whose stem grows from the very edge of its round base fits pat in tight corners, its stem against the wall, its head leaning over and its feet completely under a piece of furniture. The simple expedient of a hinge in the armature which supports shade, bulbs and sockets makes this same lamp convertible

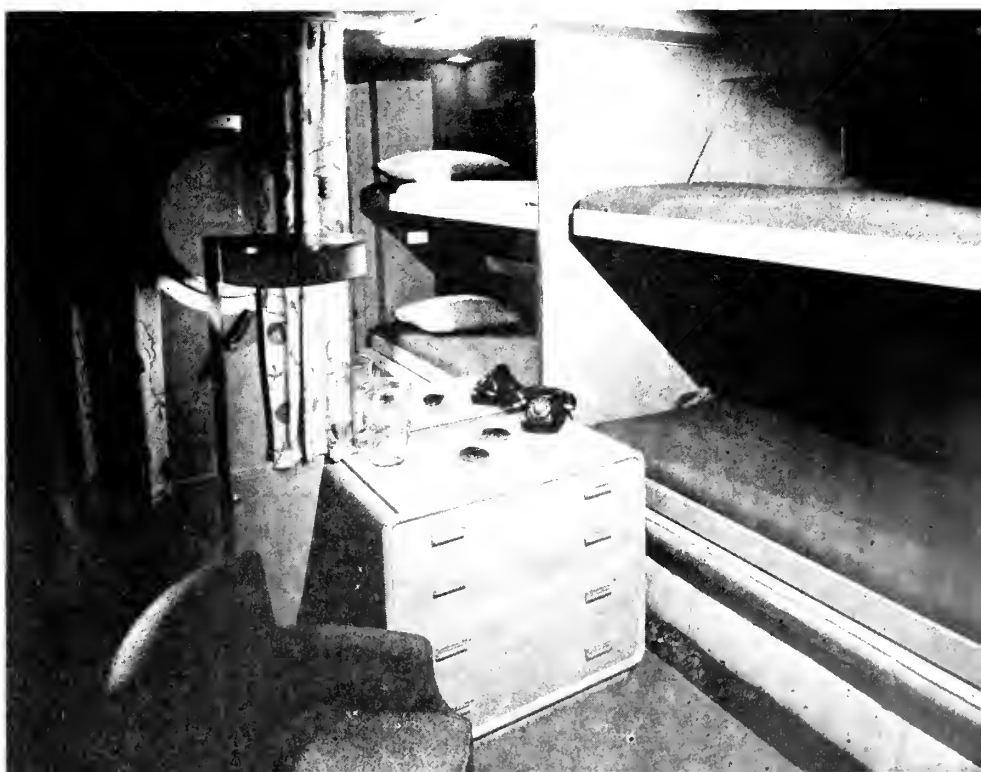
Above: **CABIN CLASS LOUNGE**

Below: **TOURIST STATEROOM —NIGHT**

from the usual indirect standing type to a direct bridge lamp.

To serve the traveling feminine world, a vanity unit is concealed in the graceful modern dresser. Miss America, or her sister, simply pulls out the top drawer of the dresser, raises and tilts back a mirror-faced lid revealing a spacious compartment made to care for small bottles, jars and such necessities. Thus, reposed in a neat vanity chair, surrounded with equipment and adequate lighting she goes painlessly to work. When she finishes, another job can be accomplished with the top down. The smooth surface of the open drawer's cover heartily suggests that the stationery in the next compartment is destined to be used for a letter home. Thus the dresser becomes a desk!

Behind the scenes, as usual, hides the construction. Upon its details, its strength, durability and flexibility for handling depends the successful culmination of design. Joiner material on these ships, manufactured and erected by Aetna Marine, fulfills this purpose. Flush, steel divisional bulk heads and similar linings are double-faced and contain an inorganic filler. The panel edges are ingeniously



formed to provide a strong interlocking joint which acts as a stiffener and thus in bulkhead erection, eliminates posts or fastenings other than retaining members top and bottom. Joiner doors and frames are fashioned to blend naturally into this modern structure, a style which is carried through, even to the Vee-joint marine veneer ceiling.

To those who wish to travel in luxury beyond that of cabin class accommodation, each ship offers two de luxe suites of three rooms each, specially endowed to please the most demanding critic. The layout comprises a real bedroom, a sitting room and a "veranda" lounge with large observation windows. Instead of creating a contrast, as in other staterooms, by setting bleached oak furniture and light shades of upholstery against darker, shadow-soft walls, the designer has done these suites in the more conventional, reverse color scheme, maintaining at the same time the simplicity and grace found in modern lines of furniture throughout the ship. With rich mahogany used for woodwork of dressers, tables and chairs, he has mixed a warm blue carpet, light pastel blue walls, textured drapery and upholstery fabrics in tones of beige, rose and dark blue, all of which blend with or complement each other. To match the woodwork, cigarette-and alcohol-proof formica used for dresser and table tops is made of "realwood" mahogany. A curvacious little end table is brought stictly up to date in material; its transparent tempered glass top is supported by delicate golden legs of anodized aluminum. Such superb surroundings suggest conveniences in the same style, and they're there in multiples of what may be found in one-room accommodations!

But let the picture of sample staterooms give a more graphic idea of useful and attractive details. In each stateroom—for comfort's sake—a "Weathermaster" unit and fan counteract the heat or cold with air conditioning and circulation. In case of any failure, airports may be opened to ocean breezes. And of course, to encourage more hot air, rooms have private phones for intraship communication, and from public booths all ship-to-shore business may be taken care of. Facilities in the tourist bathroom include a space-saving combination unit with toilet, Monel-metal wash basin, a medicine cabinet and light. Suspended on the wall are a streamlined thermo-carafe and a handy satin-finish steel Kleenex cabinet. A full-length mirror on the outside of bathroom or wardrobe doors affords a passenger opportunity for final self-appraisal before stepping out to meet the public.

Although staterooms are designed for daytime living, gregarious, fun-loving Americans will always spend more than half their waking time out on deck and in public rooms. Eating, as well as the conventional diversions of promenading, playing deck tennis, swimming, or sunning, is a favorite sport. Dining "cabin class" cannot help but be an appetizing treat in decor as well as in food. Imagine a sumptuous, Hawaiian foliage mural by a prominent artist, Andre Durenceau, blended into a soft grey-blue and beige color scheme: modern red gum buffets trimmed on top with edge-lighted Harriton carved

THE THERMOS BOTTLE*

glass panels; add comfort in gold leather chairs at regular tables or congenial chatter at diagonally patterned banquettes beneath a long range of lighted windows—it's all in one room on the President ships. Try Tourist Class—more carved glass—more mirrors, some bleached oak fluted columns—red chairs contrasting with French gray walls, and it's all done with the light hand of restraint for long durability.

A cafeteria-style arrangement for third class passengers offers quick service mid pleasant surroundings. Diners sit in well upholstered alumium chairs at spacious formica topped tables. Their lounge and smoking room has a large seating capacity, lengthy banquettes, card tables, writing desks, lounge chairs and prevailing gay, faintly Oriental atmosphere. Designed specifically for the immigrant traveler, these spaces and the third class living quarters have been handled with full knowledge of requirements, and a mind on the budget, as well as a deft space-making wand to carry comfortably and graciously all who may wish to travel this way.

Minute description of the ship's interiors, room by room, feature on feature, would make this a yarn on the installment plan. But, to be general, we could say that up on "Prom" deck there's a lot of public space, into every inch of which went months of productive thought. Renderings on these pages help tell the story and show the results till they can be seen in reality.

Since the ships will sail between the West Coast and the Orient, their public rooms have been flavored, but sparingly, with Chinese modern design. The cocktail lounge is perhaps the most evident example: the aft wall, curving out and upwards from above booths to the ceiling, is painted a deep Chinese red and adorned with a Chinese line design in gold wire. The color scheme, even the forms of chairs, tables, bar stools, their pedestals and the bar itself are reminiscent of Chinese art and architecture.

In other rooms — the masculine, mahogany paneled Smoking Room, for example — the Oriental feeling may exist only in jade handles on a modern Chinese chest, or in the decorated base of a table lamp. In the Main Lounge, a specially designed Chinese style clock, almost jewel-like in appearance, is placed in a similarly shaped niche cut in the mirror over the fireplace. Two porcelain figurine lamps sit on top of green lacquered cabinets, embellished with golden bronze trim. Faint traces of the exotic can be recognized in many other places—in a table leg, a chair back or a curving wall. But actually not half of the ship feels the influence of the Orient. Quiet, modern, American design characterizes the bleached oak paneled library and the writing room as well as the lounge and smoking room.

The Marine Veranda—as the rendering indicates—follows the suggestion of its name and creates the feeling of outdoors and a night club at the same time. Heavy white classical moldings outline doors and contrast with the dark blue walls. Windows on three sides of the room are richly draped in eggshell mohair with a banana leaf design. The orchestra backing—painted the same as the wall—is combed to show its silver lining. To carry out further the veranda effect, chairs are made of open-work cast aluminum, painted white. Pierre Bourdelle, an artist well known for his work in carved linoleum, is

COMBOLET

In Tourist Class bathrooms space saving unit combines regular toilet, folding wash basin of monel metal, medicine cabinet with mirror and lights top and bottom. Opposite is spacious "Koroseal"-curtained shower.

doing panels for the face of the movie projection booth and for wall space above the windows. (For Pursers' office lobbies, he is also doing track charts showing the course and location of the ship at sea). As in all cabin and tourist public spaces which are not carpeted, vinyl tile is used as deck covering in the Veranda. An off-white feature strip circles the midnight blue dance floor, repeating the curved design of lighting ingrown into the ceiling above the tables.

Hailed by many, of late, as the "new wonder plastic," vinyl is as yet unproved, but all tests predict that it will be the material of the future. Its wearing qualities are many times that of rubber or linoleum for floor coverings, and its surface is easily kept clean and unscarred because it is so hard. To the shipowners and operators who yearn to eliminate the expense of maintenance and replacement, vinyl tile may prove a godsend. For a dance floor, it offers a surface smoother and as danceable as hardwood. For promenade decks, it can be molded into a pattern with a semi-abrasive surface to prevent slipping in case of wet weather. For the President ships we have obtained a line of colors which will augment the appearance of any interior reds, neutral beige good for passage-ways, tones of grey or dark blue which, accented with white, may be worked into a pattern or fashioned into a feature strip to suit the design of the individual room. By various arrangements of the 9" square tiles in which it is laid, any desired effect may be obtained a pin-stripe such as is being used in the cabin class Cocktail Lounge, for example.

In two of its other forms, simulated leather and patent leather, vinyl is entering the upholstery field. A fire resistant, water-proof, highly resilient but tough material, it is used easily over rubber upholstery with no fear of stretching as leather does. In less expensive quarters, in place of shorter-lived, less attractive chair coverings, it is being used aboard the Wilson and Cleveland on banquettes and chairs in public rooms. In the Marine Veranda, a pure white patent leather type is prescribed to cover the white aluminum chairs.

On the whole, in public rooms lighting is concealed in soffits, in coves and so forth. In the Tourist Class Cocktail Lounge, a dropped ceiling with wavy edges extends the length of the room and hides fixtures which throw light down on walls covered with mirrors, and a mural. Naturally, decorative lamps are necessary and apparent to add character and touches of color to lounges and smoking rooms. Each public room or stateroom fixture, whether it be decorative per se or in its effect from a hidden source, was individually designed to do the job planned for it.

In honor of its home port, the President Cleveland will have, in its forward stairhall, stretching between Prom and Shelter decks, a perspective mural of San Francisco its hills, its bay and its bridges. Both ships will salute America with their design and decorative appointments so typical in origin, at the same time deftly introducing the fantasy of the Chinese. Several murals, both photographic and painted, will portray the reality of this country, while others will seem to wear the lei of Hawaii or bow a head to the revered ancestors of the Orient. So, to those travelers eagerly coming home to the U. S. or to those whose heads are turned with excitement towards the "Far East" across the ocean, the President ships will give first touch with what they are seeking, and at the same time they will inobtrusively provide all comforts, safety, conveniences and the facilities for a most enjoyable and happy trip on the Pacific.

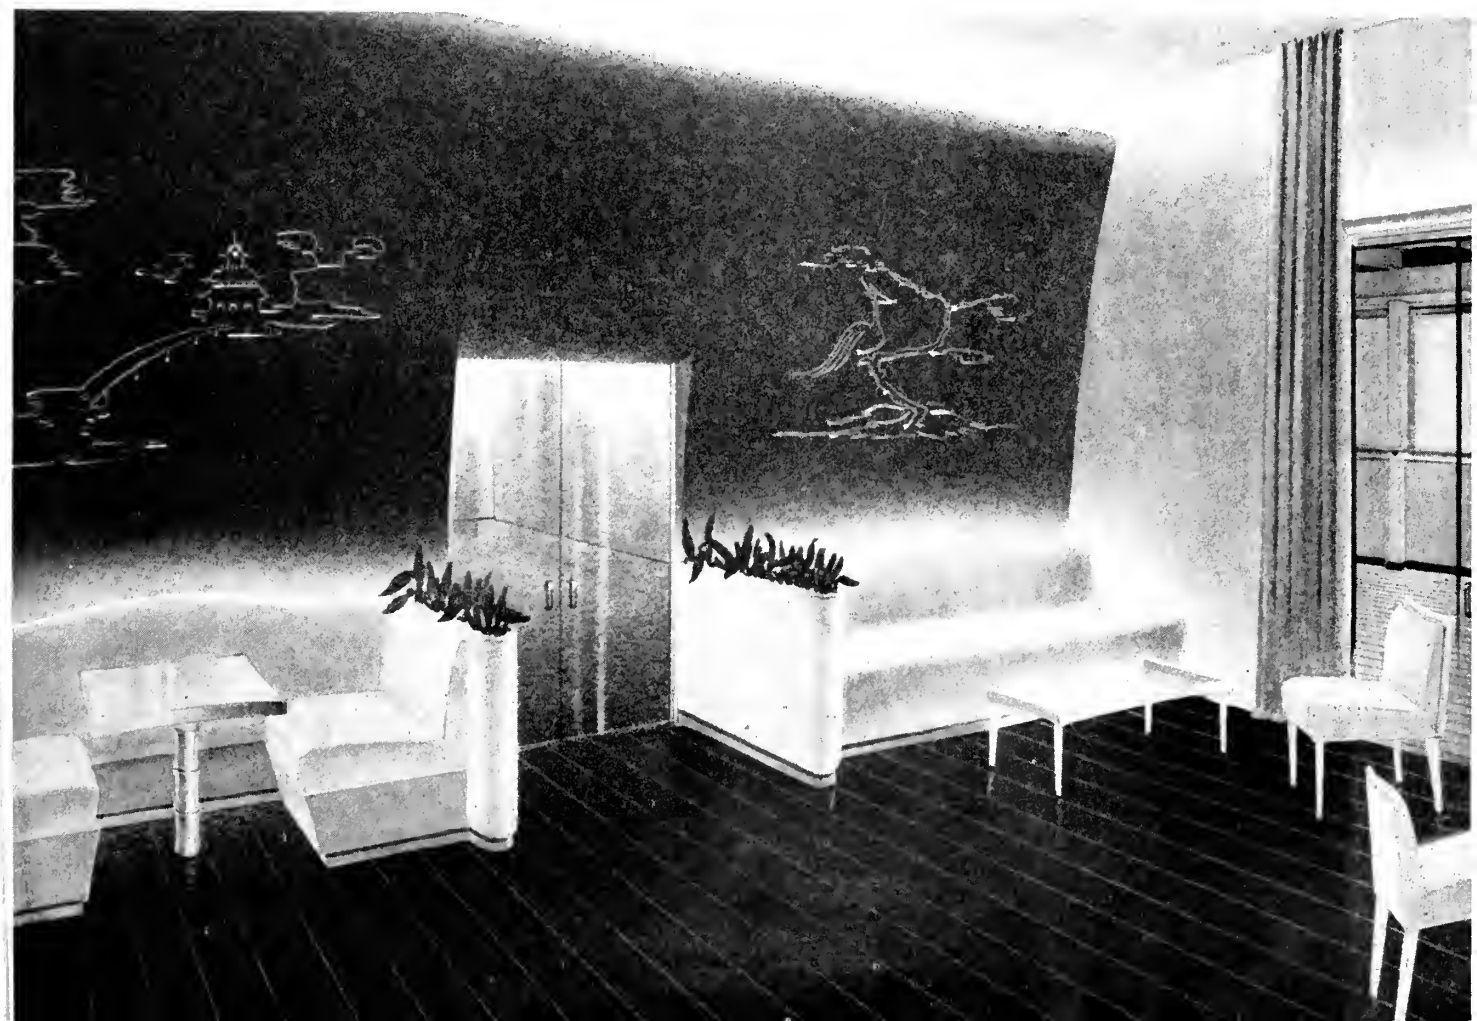
AFT WALL SHOWS TREATMENT OF CHINESE DESIGN IN GOLD WIRE



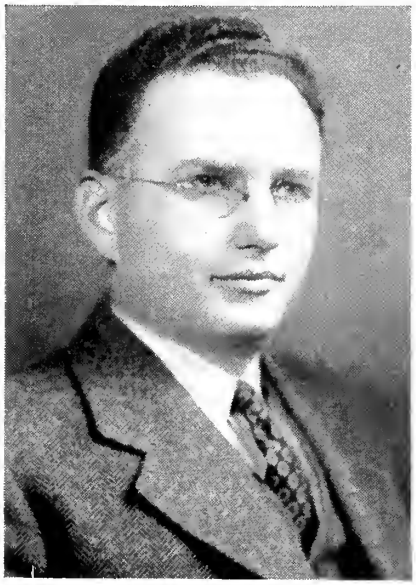
American President Lines Back In World Service

By E. Russell Lutz

Executive Vice President, American President Lines
President, Pacific American Steamship Association
Written expressly for *Pacific Marine Review,*

IN CONVERTING from war to peacetime operation, American President Lines is confronted with a number of difficulties, not the least of which stems from the unprecedented backlog of traffic, both passenger and freight, which is literally begging for shipping space across the Pacific and to ports around the world. This situation results from the inevitable timelag which occurs between winding up the traffic of war and the outfitting and equipping of suitable vessels for the commerce of peace. It is a problem more or less common to the whole maritime industry.

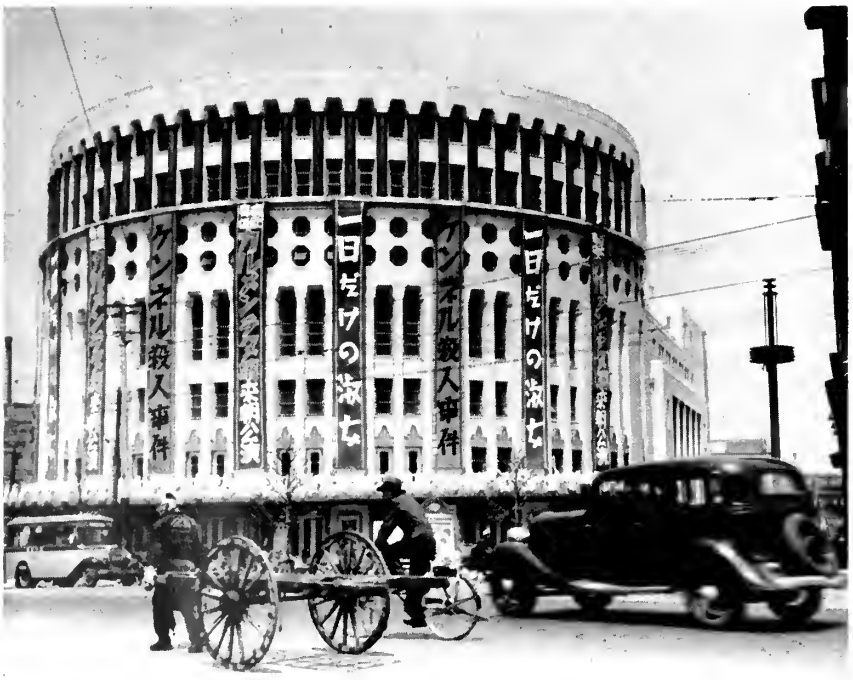
American President Lines is meeting this particular problem by acquiring certain vessels from the Government's great merchant war-built fleet, said vessels to be operated in essential services on an interim basis until such time when ships of a more permanent character, and designed especially for President Line routes, can be constructed or otherwise acquired. It is a paradox growing out of the waste and extravagance of war that in a world full of ships still more ships must be built. In no other way, however, can special trade requirements be accommodated.



E. Russell Lutz

Our company is about to take delivery of two P-2-type Navy troopships which will undergo limited conversion and then be assigned to the immediate and imperative job of relieving the transpacific traffic jam. They will continue to operate until two ships of similar hull design—S.S. President Wilson and S.S. President Cleveland—now nearing completion at Bethlehem's yard in Alameda, are commissioned into service, probably in September or October of this year. The P-2 Navy troopers will then be laid up and a real conversion job done on them. They will come out finely appointed ships, after which all four will maintain a fast passenger express schedule across the Pacific on a basis of fortnightly sailings from San Francisco and Los Angeles.

The P-2's are somewhat smaller and less pretentious than the late Presidents Hoover and Coolidge, but in many respects, notably in refinements and comforts of passenger accommodations, they will be superior to the former transpacific luxury liners. The new P-2's are 622 feet long, 76 feet wide, displace 23,000 tons and have a cruising speed of 19 knots. The Presidents Cleveland and Wilson will carry three classes of passengers with total accommodations for 552 and a full merchant crew of 331. The converted troopers will carry approximately the same totals, but will provide accommoda-



Scenes throughout this article are prewar views token along the A.P.L. routes. At left is a department store in Tokyo.

Hong Kong by day.

tions for only two classes of passengers.

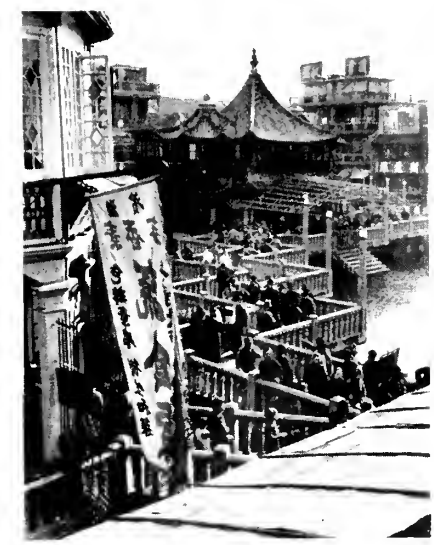
It is evident that these new P-2 President liners are all that their designers, builders and outfitters claim for them. They are truly fine ships, trim, safe and serviceable, styled and built in the best American tradition. And yet, insofar as American President Lines' long-range plans for the Pacific are concerned, they are merely interim ships; highly satisfactory for the urgent near-term job at hand, but destined within a few years to yield to even larger, much faster and more luxurious passenger express liners.

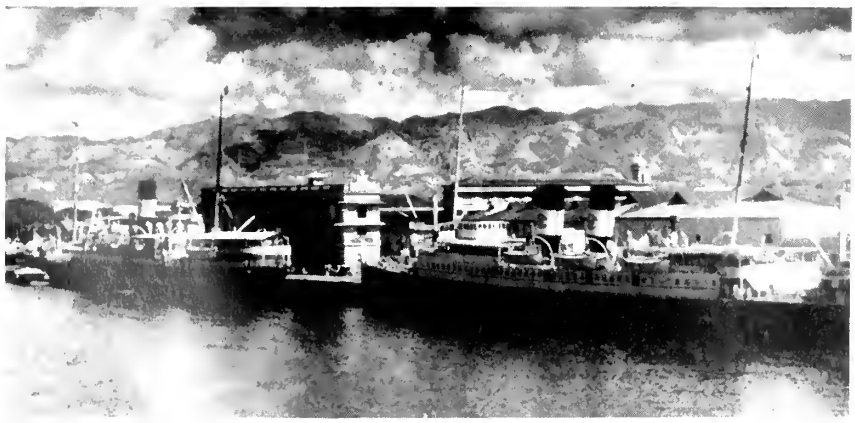
In order to bring this interim fleet into its proper perspective it is necessary to glimpse the whole of American President Lines' operations, present and projected, including the old established pre-war services plus other services for which applications are now pending before the United States Maritime Commission.

Prior to the war the company owned and operated a total of 19 combination passenger and cargo vessels, although a few of the original round-world vessels were being used solely as freighters. With a few exceptions these 19 ships were employed in three services over two essential trade routes — transpacific and around-world. Today, only three of the company's pre-war fleet remain in the ownership of American President Lines. They are the Presidents Monroe, Polk and Johnson. The first two were constructed, along with five others, for President Lines' round-world services by the Mari-

Hong Kong by night.

Scenes in Shanghai.





time Commission and were completed just before Pearl Harbor. Known as C-3P's, they were taken under charter by the Navy, and are just now being returned to the company. The President Johnson, ex-Manchuria, is an older ship which we operated as a transport during the war.

Trade routes presently accredited to the American President Lines are known as "Line A" and "Line B." These represent, however, three distinct "services," two operating over Line A and one over Line B.

Service No. 1 (over Line A) is the company's pioneer passenger express run between California ports (San Francisco and Los Angeles) and ports in Japan, China and the Philippine Islands via Honolulu, formerly dominated by the palatial luxury liners President Hoover and President Coolidge. It is for Service No. 1 that the four interim ships, known as P-2's are now being made ready. Schedule frequency: fortnightly sailings.

Service No. 2 (Line A) is a freighter service which closely parallels service No. 1 over Line A, but in which the vessels may call at additional ports as cargo offerings warrant. Minimum vessel requirements for this service, to provide 26 sailings per year, are specified as five C-3-type freighters, with 17 knots speed. The company is now operating in this trade (under WSA agreement) three such freighters, recently turned out by Western Pipe & Steel at South San Francisco. They are the Presidents Taft, Grant and Pierce. Three sister ships in the same yard are awaiting final finishing touches, currently delayed by the machinists' strike. These ships represent the last word in modern cargo carriers. They have the latest automatically-controlled refrigerated boxes, an abundance of deep-tank space for both vegetable and mineral oils, and are equipped throughout with Cargocaire.

Service No. 3 (Line B) is the company's famous and ever-popular

Top: Shanghai Bund.

Center and bottom: Shanghai Harbor.

round-the-world service over which seven comfortable combination passenger and cargo vessels on a fortnightly schedule will eventually resume calls at 22 fascinating ports in 14 countries . . . New York and Boston, Havana, Cristobal, Balboa, Los Angeles, San Francisco, Honolulu, Yokohama, Kobe, Shanghai, Hong-Kong, Manila, Singapore, Penang, Colombo, Bombay, Port Said, Alexandria, Naples, Genoa, Marseilles, then back to New York.

Minimum requirements for the round-world service are seven C-3P's of modified design, to accommodate 150 passengers. (The former C-3P's of the Presidents Monroe-Polk type accommodated only 97 passengers.) The design of the new group of vessels, which is now in progress, and their construction will take some time. These new globe-girdlers, although modest in size, will have built into them all the modern refinements and luxurious appointments known in present-day shipbuilding art. Meanwhile, until the new vessels are available, the company has made application to the War Shipping Administration for the allocation of seven C-4 freighters to be operated in the round-world service. Presumably such vessels would come from the war-built fleet. To date the company has been allocated five C-4 vessels, four with required refrigeration and deep-tank space and one without.

The three services outlined above are substantially those covered by the American President Lines' Operating Subsidy Agreement, and represent the established routes and services under scheduled operation at the outbreak of war. Since then the company has applied to the Maritime Commission for two additional services, which have been identified as Services Nos. 4 and 5.

Service No. 4 would employ a minimum of five C-3 freighters in what would be known as the Atlantic-Straits service, operating between ports on United States Atlantic Coast

and the Malay Peninsula via the Caribbean, Panama Canal, ports in California and Hawaiian Islands and ports situated in the Philippines, with privilege of calling at other ports in Japan, China, Hong Kong, French Indo-China, Netherlands East Indies, Thailand, Burma, Borneo, New Guinea and at Central and South Pacific islands lying within the general area of the route, also at Atlantic Canadian ports.

Service No. 5, known as the Pacific-India Service, likewise would use a minimum of five C-3's (freighters) between ports situated on the United States Pacific Coast and Hawaiian Islands and ports in the Philippines, Netherland East Indies, Malay Peninsula and India, with the privilege of calling at other ports in Japan, China, French Indo-China, Thailand, Burma, and Central and South Pacific islands lying within the general area of the route, also Pacific Canadian ports. Studies on essential trade routes by the Postwar Planning Committee of the Mar-

Coolie raincoats, Hong Kong.

itime Commission have led to a recommendation that this proposed India service be extended from California to the East Coast of the United States, via the Panama Canal.

American President Lines and its direct predecessors have a continuity of service between the United States and the Orient dating back more than a half century. Its famous round-world service dates back nearly a quarter of a century. The importance of these two American flag services in fostering world commerce and en-

Remnants of Spanish fleet in Manila Bay.

A small bit of the merchant marine of the Orient.

hancing the prestige of the American Merchant Marine can hardly be exaggerated. With the additional services outlined above, American President Lines will have one of the best balanced and most comprehensive operating units in the merchant marine.

Already the company has made remarkable strides on the road back to peacetime commercial operation. Those members of the organization who joined the Armed Services or took special wartime assignments with the Government are returning to the company as rapidly as they are being released. The company's training program, which had been dropped during the war, has been resumed with added features. Details are being studied with a view to integration with the G. I. training program. The planning for a post-war advertising campaign has been completed and advertisements will soon be appearing in media of large circulation. Our passenger offices, which were subleased during the war period, have been recovered and are in the process of being modernized and refurbished with a view to their early reopening to serve the public.

The company's offices have already been re-established in Manila, Shanghai, Hong Kong and Singapore, and in Naples, Italy. Another group of Far Eastern company representatives will leave soon for Japan, where they will be engaged by the War Shipping Administration until such time as they can resume commercial operations for the company. The fabled cargoes of the Far East, silk, spices and precious jewels and metals, are already making new "first" arrivals at West Coast ports on President Line ships. Soon this life-giving commerce, so vital to our own and the world's economy, will be flowing freely, on a two-way basis, through our ports for the enrichment of all mankind. American President Lines hopes to be a constant and dependable factor in contributing by ever-increasing measure to this essential public service.

Flower vendor, Hong Kong.

The P-2 Passenger Liners

President Cleveland AND President Wilson

By A. J. Dickie

A PASSENGER and cargo liner is a small city afloat and equipped with means of propelling itself over long distances and of taking care of its inhabitants in the manner of living to which they are accustomed. The changes in the design and equipment that are developed for each new liner are of great interest to the marine engineer, the naval architect, the shipper, and the traveling public. This article is written mainly with the purpose of showing the advances in these matters made by the Maritime Commission, by George Sharp, naval architect, and by the American President Lines in the hull, machinery and equipment of the P-2 design as demonstrated in the S. S. President Cleveland and the S. S. President Wilson now under construction at the Alameda, California yard of the Shipbuilding Division of the Bethlehem Steel Company.

This design was produced as a troopship for war purposes and considerable thought was expended in making it possible to convert from troopship to passenger liner with the least cost of labor and material. In January of this year we published the general arrangement plans, midship section, outboard profile and inboard profile of the passenger liner. In Pacific Marine Review for November, 1945, similar plans and profiles of the troop transport appeared. (The inboard profile and arrangement plans for Promenade Deck, Upper Deck and "A," "B" and "C" Decks are shown on the insert herewith reprinted from the January issue.) A comparison of these two sets of plans shows the structural changes made in converting from troops to passengers. The principal characteristics of the passenger liner are shown in the table herewith.

Design and construction comply with all the applicable laws of the United States and the rules and regulations of the American regulatory bodies as follows:

(a) American Bureau of Shipping for special survey to the highest class in that Bureau's Record Book;

(b) U. S. Coast Guard Division of Inspection and Navigation;

(c) International Load Line Convention;

(d) U. S. Public Health Service rat proofing instructions, and instructions for carrying and distribution of fresh water and the disinfecting of drinking water;

(e) International Convention for Safety of Life at Sea;

(f) Senate Report No. 184;

(g) U. S. Customs Admeasurement;

(h) Panama Canal Regulations; and

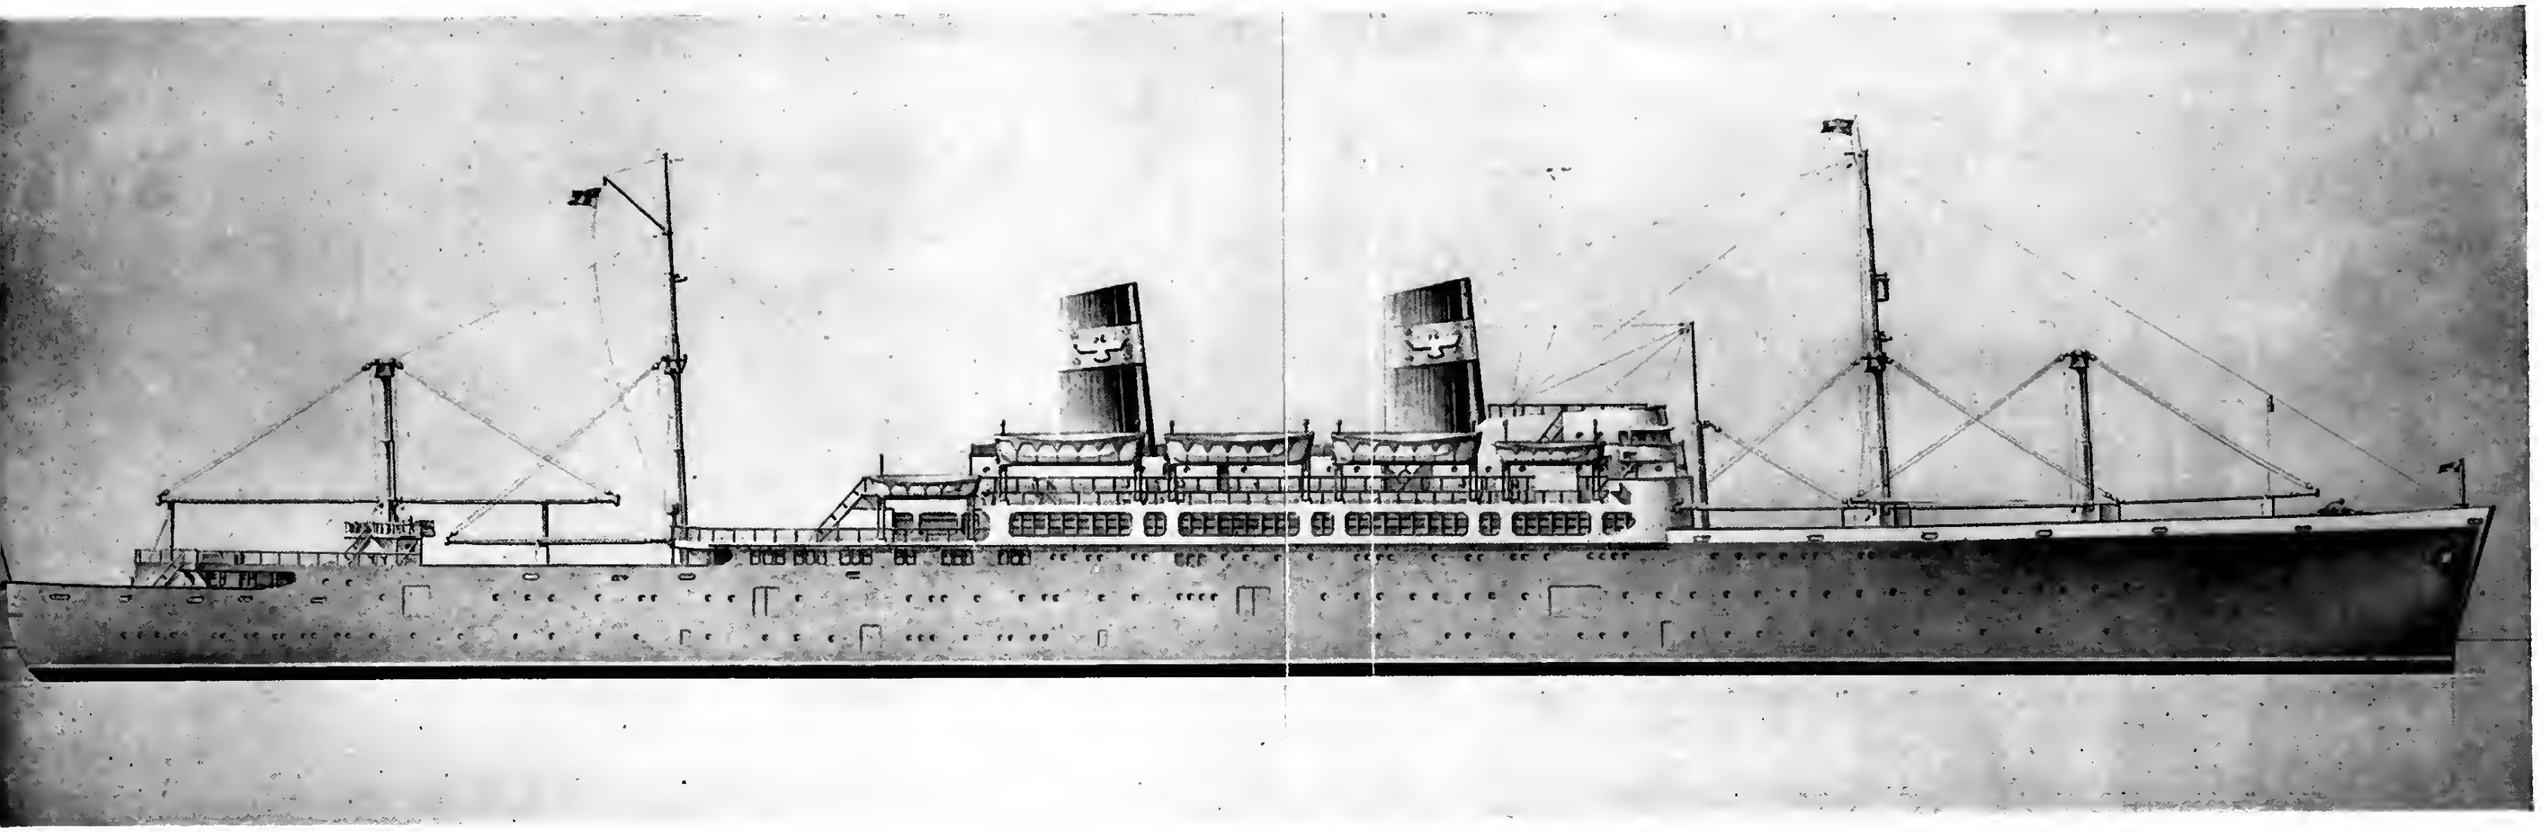
(i) Suez Canal Certificate

(Incidentally, these P-2's are the first passenger vessels built on the Pacific Coast under Senate Report No. 184).

The hull is of combined riveted and welded steel construction with a curved stem, a cruiser stern, and with three complete decks and a partial deck. These decks are designated A, B, C, and D. Above these are: an upper deck extending from the stem almost to the stern; a promenade deck extending from the stem to frame 168; a boat deck covering the midship house; and a navigating bridge deck. The midship house above the boat deck is of riveted aluminum construction which we understand saves some 75 tons in weight at a position where weight saving is important. This use of aluminum is new in merchant ship construction although the U. S. Navy has used this metal on the superstructures of destroyers and cruisers with very satisfactory service results. In this work all rivet holes are drilled or punched to a diameter 1/16th inch less than that of the rivet. After assembly and packing, with every third hole bolted, the holes are reamed to a diameter 1/32 inch larger than the rivet. Up to and including 3/8" diameter the rivets are driven and set up cold. Above 3/8 inch diameter they are driven hot.

This use of aluminum makes an interesting saving in weight and it is rather unfortunate from the commercial standpoint that in this particular hull design there is no commercial opportunity to take advantage of it by carrying more pay load. It is evident from a study of the characteristics table that in order to achieve stability under all conditions some 800 tons of fixed ballast had to be built into the hull. Thus the principal commercial advantage of the use of aluminum in the superstructure is lost by the great weight of fixed ballast necessary to maintain stability in the light condition. The hull evidently should have had four of five feet greater beam in which case somewhat less than 800 tons additional steel in the hull would give: necessary strength; additional volume providing greater hold capacity and larger and better arranged cabins; and additional displacement allowing large increase in deadweight of cargo on the same draft.

Another feature that is very noticeable in the general arrangement plans is the huge space in very desirable locations allotted to crew's quarters. Practically everything on A and B Decks forward of amidships is for the crew. Using a little "horseback arithmetic," to quote President Truman, we find that considering cabin space alone each member of the crew gets on an average 0.71 frame spaces, and each passenger gets as an average for all classes 0.473 frame spaces. Thus the average crew member, in-



P-2 PASSENGER LINERS

Artist's conception of the converted P-2 liners being completed at Bethlehem Alameda Yard for the American President Lines. Each of these two passenger liners will cost seven and a half millions for the conversion items, in addition to the seven and a half millions already expended on the vessel as a Navy transport, so that the total cost will be approximately $15,000,000 for each ship. On launching they will be christened PRESIDENT CLEVELAND and PRESIDENT WILSON.

cluding officers, gets approximately 50 per cent more sleeping space than the average passenger. On pointing out this ratio to a government shipping operator he remarked, "Why not, don't they sleep more?"

The decorative and luxury features and the construction, equipment, and arrangement of the passenger accommodations are described fully in an article by their designer appearing in this issue. We will, therefore, confine this article to the deck, navigating, cargo handling, and propulsion equipment.

All decks above A deck have both camber and sheer, A deck has sheer but no camber, decks below A have no camber and no sheer. As has been usual for some years in American passenger liners of this type, the promenade deck, in way of the house amidships, projects about 2 feet outboard from the hull, port and starboard. This serves the purpose of helping to keep boats clear of hull when lowering and allows the installation of flood lights under this overhang to illuminate the sea. It gives, of course, a wider promenade which is a decided advantage for passenger recreation and loafing space.

Provisions for air conditioning and ventilating are very complete. Air conditioning is provided: for all cabin and tourist class passenger staterooms; for a number of ship's officers staterooms and offices; for all mess rooms; for tourist and cabin class dining rooms; the library, waiting room, writing room, and shops; and for tourist, cabin, and officers' lounge rooms. Mechanical ventilation is provided for practically all the enclosed spaces on the ship. In general the air supply to all uncooled spaces is required to equal 30 cubic feet per minute for each occupant. In unoccupied spaces the air change varies from a complete change every two minutes in the battery room to a change every 30 minutes in dry cargo spaces, air supply to be for the gross cubic measure without benefit of deductions for furniture or other contents and no space to receive less than 25 cfm. Air conditioning machinery is supplied by the Carrier Corporation and the ventilating and air conditioning systems are equipped with Ilg fans. Air conditioning systems are served by heaters and cooling coils supplied by McQuay, Inc.

Deck Equipment

On the boat deck there are installed under aluminum gravity type davits 10 lifeboats as follows:

Four—36′ 6″ by 11′ 9″ by 5′ 3″, 135 person lifeboat hand propelled;

Two—36′ 6″ by 11′ 9″ by 5′ 3″, 105 person lifeboats motor propelled, and radio equipped;

Two—26′ 8″ by 8′ 3⅝″ by 3′ 7¼″, 46 person lifeboats; and

Two—26′ 8″ by 8′ 3⅝″ by 3′ 7¼″, 46 person rescue boats oar propelled.

The total person capacity here is 934, or more than enough to take care of the full complement of 890 passengers and crew.

Each pair of davits is served by an electric winch of capacity for hoisting the fully loaded boat safely at 20 fpm and for safely lowering at 100 fpm. In addition to the lifeboats there are sufficient life rafts carried to take care of 25 per cent of the total personnel. These rafts may be launched over the side or will float free in the case of sinking of the vessel. A life preserver for every person aboard and 18 life buoys are also carried for emergencies. All of the boats, davits and winches were supplied by Welin Davit and Boat Corp. All of the boats except the after pair are handled and passengers embarked from the Boat Deck. In the case of the after pair of boats they are handled from the Boat Deck and passengers embarked from the promenade deck.

The electric drive Lidgerwood windlass is mounted forward on the promenade deck and is of the horizontal shaft double wild cat double gypsy type, the entire assembly including electric motor being installed above the weather deck. This equipment is capable of hoisting two stockless cast steel anchors each weighing 15,575 lbs. and two 30 fathom lengths of 2⅝″ steel stud link chain, each weighing 11,630 lbs. at a rate not less than 30 fpm. Either gypsy head must have a line pull of 20,000 lbs. at a speed of 30 fpm. and a no load speed

The zig-zag wake of the P-2 made during the trial run as a transport. In the distance a Russian freighter heads out to sea.

of not less than 75 fpm. The motor for this windlass is rated 125 hp 230 volts, approximately 600 rpm.

The steering gear is of the Lidgerwood hydro-electric double ram four cylinder Rapson slide type, located directly over the rudder on "C" deck. It is capable of moving the rudder from hard over to hard over (70°) in less than 30 seconds when the ship is going ahead at a speed corresponding to the maximum designed shaft hp and at full load draft and in less than 60 seconds when going astern at 40 per cent of the maximum shaft horsepower. The rudder may be independently operated by either ram. The maximum working pressure ahead or astern must never exceed 1500 psi. The hydraulic pumps for these gears are in duplicate, each pump having capacity to handle the gear. Each pump is driven by a 50 hp 440 volt A.C., 3 phase 60 cycle motor operating at 1800 rpm. These motors may be controlled from four steering stations: a pair of trick wheels in the steering gear room; a mechanically connected after deck steering wheel station; the standard station in the pilot house; and a station on the pilot house top. At the last two the control is by hydraulic telemotor connection for manual steering, and by Gyro Pilot system for automatic holding to the course. Suitable switch-over arrangements prevent any interference between the steering systems.

The engineer at the controls stands by to put her "full ahead" when the skipper telegraphs the order. He is watching the General Electric propulsion control board, and it takes only a slight movement of his hand to send this P-2 clipping through the salty.

Ten single drum and six double drum electric drive winches, of double reduction gear type are provided for cargo handling at the six hatches. These winches are driven by 50 hp d.c., 600 rpm, 230 volt motors, and are capable of handling: 1½ tons at 290 fpm; 3 tons at 220 fpm; and 10 tons at 56 fpm. They were manufactured by Lake Shore Engineering Co. with motors and controls by Westinghouse.

Two 24 inch vertical Lidgerwood capstans driven by 35 hp, 230 volt d.c. motors through gearing are each capable of exerting a 20,000 pound pull at 30 fpm on warping or other hawsers. Motor and gearing are installed on deck below.

An interesting advance in the design of cargo handling machinery is the Lake Shore Engineering Co. side port loading-discharging crane for hatch No. 4 which tops on "A" deck. Two bridges each carrying one trolley and each capable of handling 2½ tons safely are installed for athwartship travel in unison. The travel of the bridges is served by a 10 hp motor; the travel of the trolleys by a 15 hp motor, and the hoist drums are operated by a 50 hp motor. A complete description of this under deck cargo hoist will be found in a separate article elsewhere in this issue. The bridges at the limit of their travel have sufficient outboard pro-

jection to give the trolley 15 feet clearance from ship's side.

Another interesting item of cargo handling equipment is a pair of portable cargo oil pumps supplied by the Waterous Company. These are of the rotary type with herringbone reduction gears driven by Westinghouse 30 hp, 1800 rpm motors and each pump will discharge 350 gpm against 100 psi with 440 rpm of the pump rotors. These pumps are handled by three electric motor drive whip type hoists each with a capacity for lifting two tons at 25 fpm.

Two elevators by Otis are installed, one for passengers and one for baggage each capable of lifting 2000 lbs. at 100 fpm. The passenger cage travels from "B" deck to the promenade deck and the baggage elevator from "C" deck to the upper deck.

Navigating Equipment

The pilot house, navigating bridges and pilot house top are equipped with all the most modern devices for making navigation simple and safe.

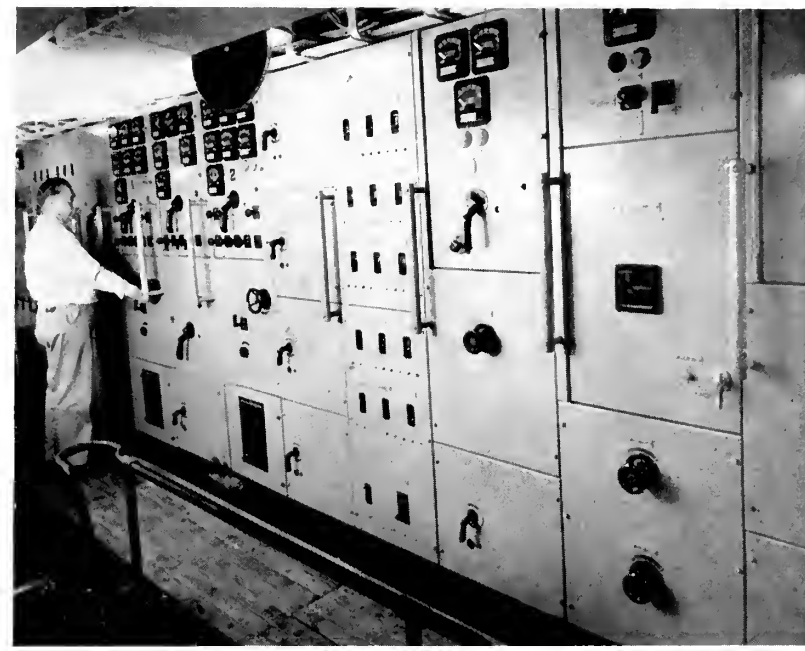
Gyrocompass system includes one Sperry Mark XIV master gyrocompass and eight repeaters mounted and located as follows: steering type repeater on gyro pilot control stand in wheelhouse; steering type repeater on column stand on wheelhouse top; bearing type repeater on column stand at after steering station; bearing type repeater on column stand, port and starboard on bridge wings; bearing type repeater bulkhead mounted in master's office; steering type repeater bulkhead mounted in steering room; and repeater mounted in radio direction finder. An automatic course recorder of the gyrocompass repeater type in the chart room keeps accurate records of all courses.

A Sperry gyro-pilot system is installed which provides complete and independent electric telemotoring for either manual or automatic control of the stroke of the main steering gear pumps. The control unit of this system is mounted in the wheelhouse.

A Submarine Signal Co. echo depth sounder provides visual and recorded reading of the depth of water under keel. This instrument has a range of from three fathoms up and its readings are accurate within 2 per cent.

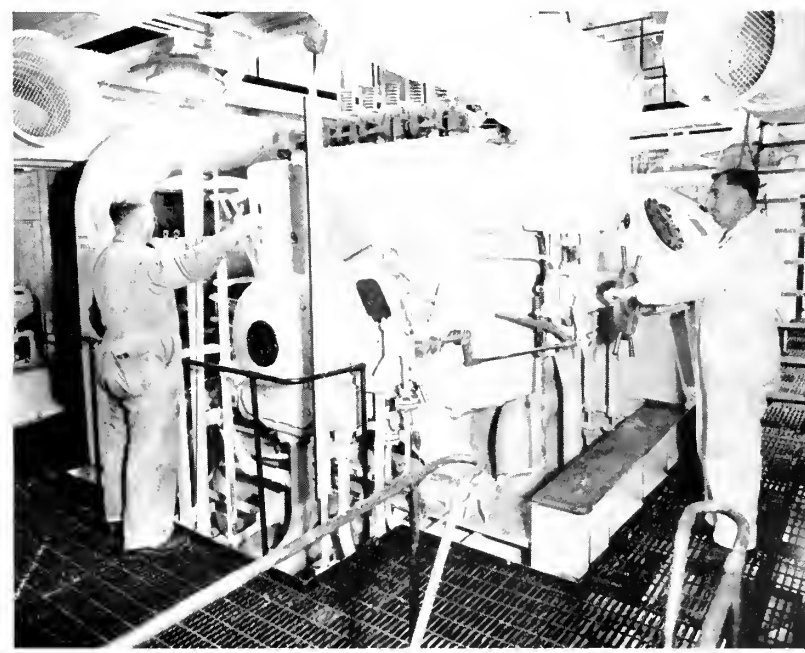
Two systems of sound powered telephones are used. System A keeps the wheel house in communication with: the wheelhouse top; the chart room; the forecastle head; the crow's nest; the captain's office; the radio room; the stern capstan; the steering gear room; and the after steering station. System B connects the wheelhouse with: the forward engine room operating station; the after motor room; the Chief Engineer's office; the emergency generator room; the steering gear room; and the electric distribution room. Voice tubes connect the wheelhouse with the radio room, the wheelhouse top, the master gyro room, and the captain's stateroom.

Port and starboard propeller shaft revolution indicators indicate the rpm and direction of rotation of each propeller. A waterproof mechanical



One of the auxiliary control boards.

Turbine-generator unit.



seven digit counter and electrical transmitter are installed on each shaft and waterproof electrical indicators: at each engine control stand; on forward bulkhead above windows in the wheelhouse; and in the chief engineer's office.

A Navy standard magnetic compass with complete azimuth circle is mounted on top of wheelhouse; a standard magnetic steering compass and binnacle in the wheelhouse; and a standard magnetic steering compass at the steering station aft.

Complete General Electric equipment for radar navigation will be installed so that regardless of visibility the navigating officer will be able to detect visually any approaching vessel or other floating object and any landfall in ample time to avoid collision or stranding.

The radio direction finder will be the latest model of the Marine Corporation of America and will be located in the chart room.

A Tyfon whistle and whistle control with control stations in the wheelhouse and on the navigating bridge, port and starboard, is arranged for both electric and manual operation.

The ship's radio telegraph and telephone installation will be supplied by R.M.C.A. and will consist of four radio telegraph transmitters of various frequencies and four receivers of various frequencies covering all the regular and emergency requirements of a passenger liner radio service. A harbor type radio telephone transmitter receiver takes care of ship to shore conversations in or near harbors. Each motor lifeboat is equipped with a radio telegraph transmitter and with a storage battery of sufficient capacity to operate this transmitter receiver continuously for at least six hours.

In connection with the ship's radio there will be installed an automatic alarm that responds to the ship's radio call letters and rings bells in the pilot house, in the radio room, and in the radio operator's cabin.

One broadcast and high frequency receiver will be provided together with loud speakers in the mess rooms, the dining rooms, the lounges, the dance floor and in other public rooms to provide for entertainment of passengers and crew.

On the pilot house top, in the pilot house, on each wing of the navigating bridge, and at the after steering station there will be installed transmitters for the Henschel electric engine-order telegraph. Two receivers for this systm are located in each of the engine rooms.

Safety Systems

A complete C-O-Two Fire Equipment Co. fire detecting and extinguishing system provides detection of smoke by eye, ear and nose through a cabinet in the wheelhouse which indicates the space from which the smoke comes and is combined with a carbon dioxide fire extinguishing system in all the spaces covered. These spaces include: cargo holds, cargo 'tween deck spaces, trunks to cargo spaces; and special cargo lockers; paint and lamp rooms, carpenter shop, engineer's paint locker and oil lockers; wiring trunks; provision and other store rooms. Separate C-O-Two systems are provided for the machinery spaces and for the gyro room, the projector booth film locker, the emergency generator room and similar spaces.

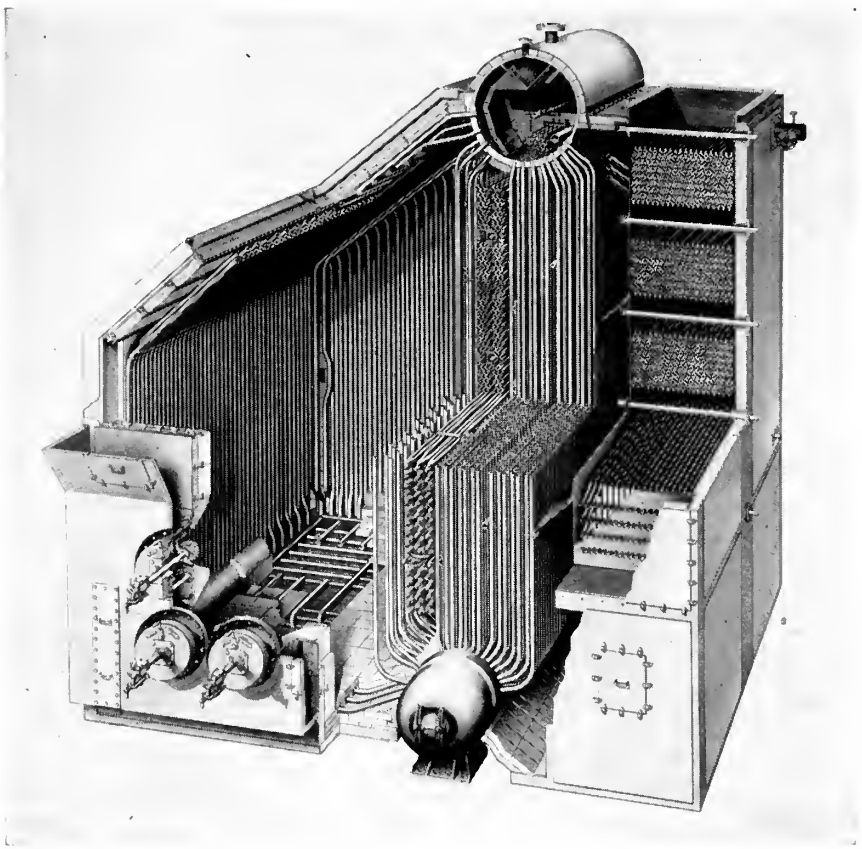
In each engine room a hose reel unit is installed having two 50 lb. carbon dioxide cylinders and sufficient length of flexible reinforced hose to reach any part of the space.

The special C-O-Two hose reel fire extinguishing equipment for the propulsion generators and propulsion motors is furnished by Walter Kidde and Company, Inc.

A complete water fire extinguishing system is served by four horizontal centrifugal pumps, two in each engine room. Each of these pumps is driven by a 50 hp motor and has a capacity for 400 gpm against 55 psi or 225 gpm against 125 psi. This system has an 8-inch pressure gage located in the fire control room so that the watchman on duty there can see at all times that the necessary pressure is maintained. Fire hydrants and hose racks are installed so that any point may be reached by two separate hose outlets.

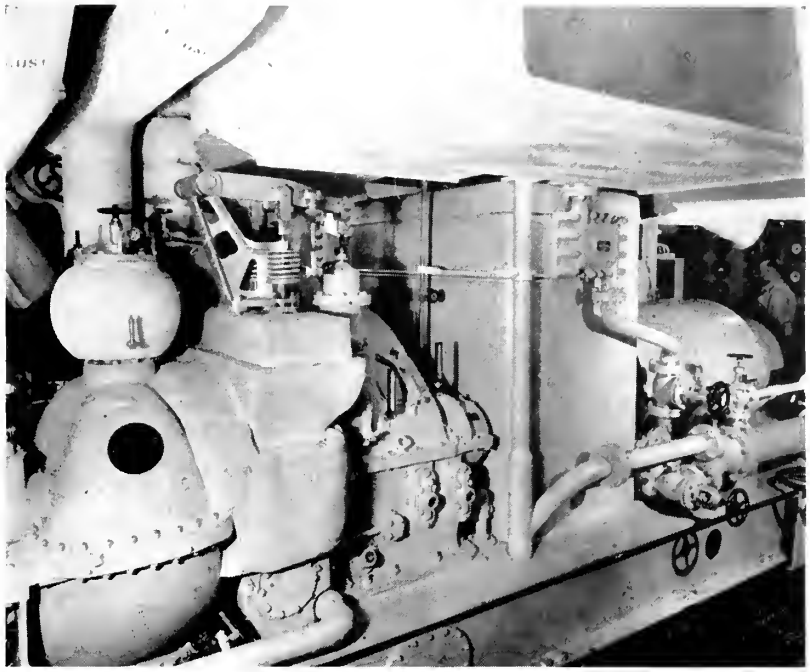
An electrical thermostat and annunciator system covers all spaces not protected by the smoke detection system, and this system will ring an alarm and indicate space and zone affected on an annunciator panel in fire control room. Fire doors are fit-

Cutaway view of one of the four boilers, showing the interior arrangement of boiler tubes, superheater tubes, and economizer tubes.



ted to stairway enclosures and to fire screen bulkheads. These are of the hinged self-closing type and can be released by electric control from the Fire Control room. A system of watchman's clocks monitors the watchmen and is supervised by the fire control room. Thus a man on watch in the fire control room can supervise all fire risks and extinguishing systems on the vessel and promptly apply the water or the CO_2 to the best advantage.

Watertight doors of the electrically operated horizontal sliding type are fitted between the motor rooms and the shaft alleys and between the motor rooms in the centerline watertight bulkhead. Same type doors provide access through the watertight bulkheads on "B" and "C" decks. These doors are controllable locally and from a central control station.



One of the auxiliary turbines. There are two of these installations in each engine room to supply power for refrigeration, pumping, lighting, etc.

Refrigeration Machinery

There are thirteen refrigerated cargo compartments in each vessel with a total volume of 52,350 cubic feet. Estimated load for the total volume with each compartment maintained at the most severe conditions is 90.05 tons of refrigeration.

The nine ship service compartments have a total volume of 17,575 cubic feet.

In addition to the above there is the refrigeration load in connection with the extensive air conditioning system. Each of these is a separate system of the direct expansion Freon type.

All the machinery for these systems is installed in one compartment.

For cargo refrigeration there are three Frick Freon-12 systems, each compressor being driven by a d.c. 240 volt 100 hp Westinghouse marine type motor.

For ship's service there are six sets of Frick Freon-12 systems with compressors driven by 15 hp d.c. 240 volt Westinghouse marine type motors.

On the air conditioning load there are two Carrier systems each served by a Carrier multi-stage centrifugal compressor. One compressor is driven by a 150 hp 3 phase 60 cycle 440 volt a.c. Westinghouse marine type motor, and the other by a reduction geared steam turbine. This air conditioning refrigeration takes care of the cooling of air for the cargo hold air conditioning system in addition to the extensive air conditioning load for the passenger and crew accommodations.

The pumps for these refrigerating systems are Warren Steam Pump Co. centrifugals.

Propulsion Machinery

The P-2 design is for turbo-electric drive and its most distinctive feature is the complete separation of its two power plant units and of its two motor units. Each power unit comprises two Combustion Engineering Company boilers generating steam at 600 psi and 840°F for a General Electric turbo generating set that has an output of 6890 K.W. at 3500 volts

One of the 10,000-hp propulsion motors. Completely enclosed, these synchronous motors are cooled by a recirculating air system and the heat is released to the atmosphere through a surface air cooler.

In the forward engine room.

3 phase 60 cycle at 3600 rpm and supplies this current to a synchronous propulsion motor normally rated 9000 shp at 120 rpm and with a maximum capacity for 10,000 shp at 124 rpm—3610 volts. Each generator is normally at full power direct connected to one of the motors giving a normal shaft horsepower of 18,000 on the twin screw propellers or a maximum rating of 20,000 shp.

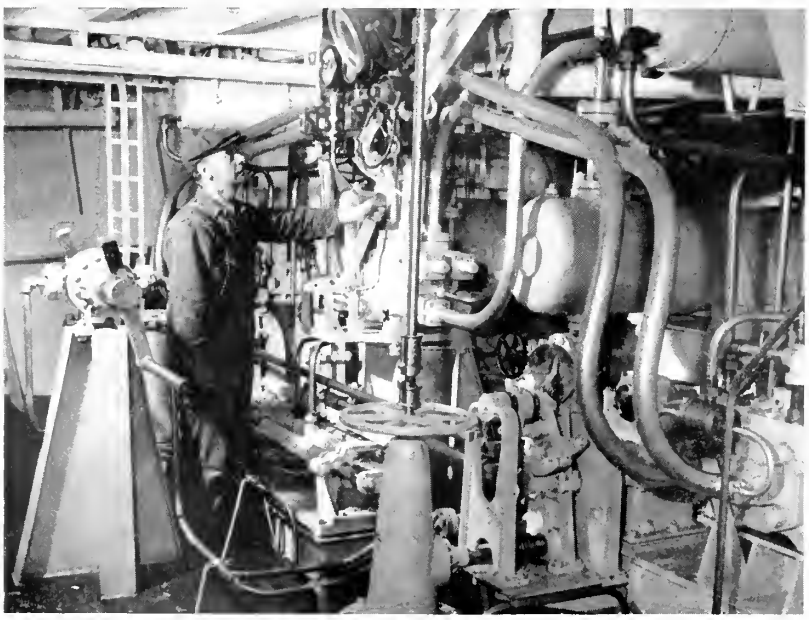
In each engine room there are two General Electric five unit turbo-generating sets. Each set consists of a steam turbine rated 600 K.W. at 10,033 rpm connected, through an enclosed reduction gear, to a 500 K.W. 450 volt 3 phase 60 cycle 1200 rpm a.c. generator, a 200 K.W. 3 wire, 240/120 volt 1200 rpm d.c. generator, and a booster exciter 750 amp. at 100 volts 1200 rpm. The a.c. generators supply power for general auxiliary ship's service. The d.c. generators supply excitation current for the propulsion generators and the propulsion motors.

The boilers in each engine room are served by Hagan Automatic Combustion Control equipment that maintains a constant steam pressure and the correct fuel and air ratio for complete combustion of fuel. Todd Hex-Press oil burners take care of correct atomizing of the fuel. Copes thermostats mounted at the front of the boiler drum operate the feed water regulating valves. Reliance water gages are used to indicate the water level. In each boiler uptake there is installed a Wager smoke indicator. In each boiler 10 Diamond Soot Blowers are fitted—three in the superheater section, two in the small boiler tube bank, and five in the economizer. Three Crosby safety valves protect each boiler, two in the drum and one at the superheater outlet. All the miscellaneous valves used in these boilers are Edward with EV alloy seats. Furnished with the boilers for cleaning the interiors of tubes are Wilson pneumatic turbine drive tube cleaners.

Specifications call for a maximum consumption in each boiler of 3002 lbs. per hour of 18,500 B.T.U. oil. That would be 12,028 lbs. per hour for all four boilers which figures at close to 0.66 lbs. of oil per brake horsepower hour for propulsion or something like 0.635 lbs. per shp hour for all purposes. This indicates a very high boiler efficiency and also the importance of the steam generator in low fuel consumption per unit of power. As will be noted in the cut-away view herewith the sides and rear of the furnace space are lined with 2" water-wall tubes. On the uptake side there are three rows of these 2" tubes, back of which are the superheater elements which are held in position by two sets of alloy support castings clamped at each side to two pairs of 2¼ inch support tubes. Back of the superheater is a bank of 1¼ inch boiler tubes. Two baffles and a partition plate direct the flow of the hot gases up through the superheater elements, down through the bank of 1¼" boiler tubes, and up through the economizer. The feed water enters the economizer at the top and emerges at the bottom on its way to the boiler steam drum. An economizer is thus a last stage feed water heater utilizing the heat left in the combustion gases from the boiler furnace.

A forced draft blower is provided

In the steering gear room. The vessel is normally steered from the wheelhouse, not from this location.



for each boiler. This blower takes its suction air from the machinery space and delivers it to the furnace front of the boiler through an air preheater which is heated by 75 lbs. steam bled from the main turbines. This pre-heater raises the combustion air from 100° F to 280° F.

Two fuel oil service pumps each capable of serving both boilers are provided in each engine room. These pumps take suction from the fuel oil settling tanks and deliver it to the burner headers on the boiler fronts through the fuel oil heaters. Three of these heaters are provided in each engine room. Any two are capable of heating 6500 lbs. of Bunker C fuel oil per hour from 100° F to 230° F when supplied with steam from the contaminated evaporator at 50 psi gage. The water drains from all oil heaters are pumped to the contaminated evaporator where they are heated to wet steam at 100 psi by desuperheated steam at 250 psi.

Steam from the boilers comes through a short pipe lead to the main turbine in each engine room at 590 psi 815° F total temperature for normal operation at 9000 shp and at 585 psi 845° F total temperature for maximum output at 10,000 shp. The turbines are of the impulse reaction General Electric type. Each turbine is mounted over and exhausts directly into its condenser which is of capacity to maintain a vacuum of 28.75 inches hg when its unit of the propulsion machinery is developing 9000 shp ahead with normal extraction from the turbine. Condensate and feed water system is of the closed type and follows the U. S. Navy-Maritime Commission flow type that has become practically standard on marine turbine drives. There are two condensate pumps to each condenser. The suctions of these pumps connect to the hot well under the condenser. The discharge is through the intercondenser of the main air ejector, the drain cooler, the gland cooler, the after condenser and the first stage heater to the deaerating heater. From the deaerating heater one of the two main feed pumps takes the feed water and discharges it through the economizer to the steam drum of the boilers. A 20-ton distilled water tank in each engine room provides make up feed where necessary. Each auxiliary condenser is served by a similar condensate and feed system discharging to the deaerating feed heater. Arrangement of piping and tankage in each engine room provides for feeding of boiler compound into the feed pump discharge.

Steering in the wheelhouse.

Each main generator is equipped with a totally enclosed ventilating system having fans integral with the generator rotor. The air coolers are mounted below the generator frame. Cooling water is forced through the tubes of these coolers by a motor driven pump and the capacity is such that at maximum power requirement the ventilating air must be kept at 40°C when the circulating water enters at 85°F. The same type of ventilating system with the same requirements is used on the propulsion motors with the exception that the fan is external and operated by a separate motor.

A main control panel in each engine room adjusts the circuits between each main generator and its corresponding propulsion motor. These panels are of the dead front type. Combined with transfer panels in the motor rooms these panels make possible any workable combination of generators and motors.

With the exception of the main feed pumps and a few stand-by pumps practically every auxiliary machine on these ships is motor drive. All of the auxiliary power circuits and lighting, cooking, and heating circuits are distributed from the switchboards in the main engine rooms through a panel board system. The panel boards, the motor controls and practically all of the motors in these systems are supplied by Westinghouse.

Culinary Equipment

There are three galleys on "B" deck that in combination with dumb waiter service and pantries provide good food for the three classes of passengers, the officers and the crew. These galleys are equipped with the most up-to-date electric ranges, charcoal broilers, coffee urns, bains-marie, baking ovens, mixing machines, and all the other items that are required by the up-to-date chef and his various assistants. Blickman Bros. are supplying the galley and pantry equipment.

It will be apparent from the foregoing rather sketchy description of these vessels and their equipment that they are complicated intricate mechanisms complete in themselves to transport and care for all the needs of nearly 900 modern luxury-loving humans.

The Alameda yard of Bethlehem has already completed successfully several hulls of the same model propelled by the same power plant and outfitted as troop ships. These vessels have made many transpacific voyages with great satisfaction to their operators. The President Wilson and President Cleveland will be the first passenger liners anywhere near this size built and equipped on the Pacific Coast. Therefore, the Pacific Coast ship operators and ship experts are watching the progress and will await the trials and the maiden voyages of these vessels with more than usual interest.

SHANGHAI PORT FACILITIES

The China-America Council of Commerce and Industry has made available to its members a special report giving existing conditions and aids to navigation in the Yangtsze River approaches and the present Shanghai port and drydock facilities. The report, 49 pages of text and many charts, was prepared on the spot under the direction of U. S. Navy personnel and is as recent as December 1, 1945. Through the cooperation of the Council, Pacific Marine Review is privileged to publish the charts shown on these pages.

The Future of U. S. Navy Plastic Type Antifouling Paints in Commercial Shipping

By

A. E. Burns, Jr.
Paint Chemist, Mare Island Naval Shipyard

Lt. Comdr. F. J. Dannenfelser, USNR
Former Docking Officer, AIM, S. F.

Lt. R. M. Mueller, USNR
Former Hull Inspector, AIM, S. F.

This is a paper presented at the February meeting of the Northern California Section of the Society of Naval Architects and Marine Engineers, which meeting is more fully reported elsewhere in this issue.

Comments from the floor following the reading by Mr. Burns served to point out the difference between Navy practice during war conditions and peacetime commercial practice, with particular emphasis on costs, and also on the utility of certain proprietary paints made especially for particular types of cargo vessels and in certain zones of operation. A factor of great importance in any comparison is the rule requiring annual drydocking of commercial vessels under which the item of drydocking costs shown in the charts would be materially affected—Ed.

MARINE FOULING is an age-old problem which has been estimated to cost the shipping industry of the United States at least $100,000,000 per year. Many surveys have shown that fouling on vessels can result in losses of top speed approaching 50% and fuel consumption increases of at least 40%. In extreme cases large vessels have collected several hundred tons of fouling having an average thickness of over 6 inches. It has been the practice of the British Admiralty, for design purposes, to allow for an increase of frictional resistance of ¼% per day out of dock in temperate waters and ½% per day out of dock in tropical waters. Such inefficiency in ship operation has generally been accepted as a necessary evil which can be controlled only by frequent and expensive dockings.

Although a myriad of fouling forms exist, examination of several hundred vessels which had operated under a wide variety of conditions has shown that barnacles, worm tubes, hydroids, algae, sea squirts and molloses are the only organisms which seriously affect ship operation. Barnacles and hydroids appear to be the most dangerous forms for ships operating in temperate waters. Together with worm tubes these same organisms constitute the most serious fouling hazard to ships operating in tropical waters. Very heavy mollusc and sea squirt fouling is frequently observed on hulls which have been moored for periods exceeding six months but these organisms are seldom observed on active ships. Algae fouling is encountered on almost all vessels, but this growth is generally restricted to a narrow belt at the water line.

It is well established that practically all fouling results from the attachment and subsequent growth of larvae or underdeveloped juvenile fouling organisms which are brought into contact with a ship's hull by water currents. The larvae form a temporary and generally weak attachment which rapidly increases in strength as the organism grows. Recent work has demonstrated that the common fouling larvae are not capable of attaching to a flat surface moving at a speed of more than 2 knots and that speeds in the excess of 10 knots will remove most fouling organisms up to one week after the initial larval attachment. It is obvious that fouling attachment does not occur while vessels are under way but only during inactive periods in a harbor or at a mooring. Thus ship operation can have a large effect upon fouling attachment, since vessels which are in port only for short intervals rarely foul.

Most fouling organisms are indigenous to shallow water and do not occur in the open sea where few surfaces are available upon which they may attach and grow. The only fouling larvae in the open sea are those carried by ocean currents from an

---

Battle of Barnacle Hill

Oh, the barnacle is a curious thing,
It has such stick-to-it-ive pride;
In its realm it is known as King of Cling,
With many fine ships to ride.

Some barnacles are quite choosey, too,
Having their specific hankers;
They won't lounge on rocks to bill and coo
If they can cruise on husky tankers.

But there are many kinds of barnacles, lad,
And they all cut your speed, 'tis true;
They're a weight and a drag that drive men mad—
So don't let 'em get on you!

—Barnacle Ballad

area where colonies of adult organisms exist. As a result there is little chance of fouling attachment at any great distance from the coast line.

During the past 2000 years many people have attempted to develop antifouling ship bottom coatings, almost invariably without success. A large number of theories have been propounded whereby fouling could be either killed or repelled. Perhaps the most popular of these has been the theory that fouling organisms could be poisoned or repelled by toxic or noxious substances incorporated in ship bottom paints. As a result almost every disagreeable or poisonous substance available has been tested as an antifouling agent. Another interesting theory has been the proposed use of exfoliating paints which chalk or flake off in successive thin layers, thereby preventing fouling growths from developing a firm attachment. Since the larvae of many fouling organisms are negatively phototropic and do not attach as readily to light as to dark colored surfaces, the use of light colored paints has been proposed as an antifouling remedy. Other workers have proposed the use of slick, resilient, smooth, non-wettable, greasy or hard coatings to which fouling organisms presumably could not attach, this being known as the surface texture theory of fouling prevention. Electric currents, high pressure steam, revolving knives, under water concussions and many even more visionary schemes for the elimination of fouling have been recommended at various times.

Probably the first effective antifouling coating to be employed on ships was copper sheathing, introduced by the British Admiralty during the 18th century. This material was expensive and difficult to maintain but was quite effective in preventing fouling attachment and teredo attack. As a result copper sheathing was widely adopted and soon became a standard treatment for wooden vessels.

With the development of iron ships, bottom fouling again became a serious problem. It was soon found that copper sheathing, which proved so effective on wooden ships, could not be used on iron ships. The galvanic couple established by contact of iron plating with copper sheathing in sea water resulted in rapid corrosion and destruction of an iron hull. In addition, since iron coupled copper sheathing is cathodically protected

and no longer free to corrode, soluble toxic copper is no longer available at the surface to repel fouling growth. As a result the coupled copper sheathing has very poor fouling resistance.

The failure of copper sheathing on iron ships stimulated the search for effective antifouling paints. By the end of the 19th century a few moderately statisfactory paints had been developed and put into general use. Perhaps the best of these were the hot metal composition of McInness, the tar base paint of Tarr and Wonson, the shellac base paint of Rahtjen and the hot melt composition developed in Italy, known as Italian Moravian. As far as is known all these materials employed copper, mercury or arsenic compounds as toxics to inhibit marine growth. Although relatively poor by today's standards, these paints were a notable advance over the previous ineffective compositions.

The U. S. Navy commenced manufacture of ship bottom paints for its own use in 1908 at the Norfolk Navy Yard, being forced to this action by the unavailability of standardized, effective commercial compositions. The first Navy antifouling paint utilized shellac as a binder and mercuric oxide as a toxic pigment. This paint, or modifications thereof, constituted the standard antifouling coating of the Navy from 1908 until 1926, when formula 15RC was adopted for general use. Formula 15RC utilized a coal tar plasticized rosin binder and contained both cuprous and mercuric oxides as toxic pigments. This coating, which had an effective life of 3 to 6 months in waters of high fouling intensity, was abandoned in 1939 in favor of the far superior Mare Island hot plastic paint. An antifouling paint, very similar in composition and effectiveness to the old formula 15RC, is currently used in large quantities by the U. S. Maritime Commission. Many presently available commercial antifouling paints are also similar in composition and performance to the 15RC formulation.

In 1922 the Chemical Warfare Service at the Edgewood Arsenal was requested by the Navy to undertake an antifouling paint research program. Since Italian Moravian, a hot melt composition manufactured in Italy, was generally conceded to be the most effective antifouling paint available at that time, a major part of the Edgewood Arsenal work was

directed toward the formulation of hot melt coatings. A large number of compositions were developed and tested by panel exposure at Beaufort, North Carolina. In 1924 the most promising hot melt composition was applied to a naval vessel. However, the paint proved only moderately successful in ship service tests and eventually the Mare Island Navy Yard undertook the development of hot melt coatings, using the Edgewood Arsenal research as a starting point. After several years of empirical research this Navy Yard developed a new hot melt paint which differed widely from the composition of either the Moravian or Edgewood formulations. Extended ship service tests indicated the Mare Island hot plastic to have outstanding performance and led to its eventual adoption as the standard Navy antifouling composition, which, in somewhat modified form, it remains today. The almost startling contrast in performance between the Mare Island hot plastic and old formula 15RC is illustrated by figures No. 1 and 2.

Prior to the Mare Island developments, hot melt compositions had been melted, poured into paint pots and swabbed on a hull with ordinary paint brushes. The first applications of the Mare Island hot plastic were made in a similar manner. It was recognized that this method of painting had serious limitations, and Captain A. S. Pitre, USN, who had been placed in charge of ship bottom paint research at Mare Island, conceived and pressed the development of hot plastic paint spray equipment which would allow the rapid and uniform application of hot melt coatings. After much experimentation, satisfactory electrically heated pressure pots, spray hoses and spray guns were developed. This equipment made practical the present large-scale use of hot plastic paint.

The name "hot plastic paint" has frequently been termed a misnomer, since this hot melt composition bears little resemblance to an orthodox paint. By strict definition, the material is not a "plastic," this term having been employed, perhaps inadvisably, because of the composition's physical properties. Hot plastic is a resinous composition which exists as a soft, somewhat plastic solid at room temperature and melts rather sharply at about 130°F. It is quite fluid at higher temperatures and has a very low viscosity at 300° F., the normal application temperature. When sprayed onto a hull, the molten, solvent free composition cools and solidifies almost instantaneously. Thus no "drying" period is required and a ship can be undocked immediately after painting.

Since its adoption as the standard Navy paint in 1939, hot plastic has been used in very large quantities to coat practically all major units of the fleet. Although the Pacific fleet operated throughout the war in prolific fouling waters, ship fouling never became a serious problem. Vessels operated at high efficiency for long periods out of dock and were seldom docked primarily for bottom painting. Based upon this experience, it can be safely stated that hot plastic paint has established an entirely new standard of antifouling performance far superior to anything attained previously. The excellent performance of this paint on naval vessels is illustrated by Figures 3 and 4, 5 and 6.

The outstanding durability of hot plastic paint can be attributed to several factors. The paint has been carefully designed to liberate copper toxic at an adequate but not excessive rate during its entire life. Its average copper leaching rate generally falls in the range of 10-15 ug/cm²/day. On panels the paint has given complete protection from fouling for over 5 years. A normal application contains sufficient toxic for at least a 10-year life. The physical durability of hot plastic results largely from the fact that it is a hot melt coating. Up to 50 mils of paint is applied in a single pinhole-free coat to provide an essentially water impermeable barrier. As long as the antifouling film is physically intact, the underlying steel hull is completely protected from corrosion. Thus the superior corrosion resistance of the hot plastic paint system results from the use of a very thick, water impermeable antifouling film. With solvent type antifouling paints 5 to 10 coats are required to obtain a film thickness equivalent to hot plastic. A solvent applied antifouling film is always more permeable and less durable than a hot melt film of equal thickness and similar composition.

As might be expected, hot plastic paint has several weaknesses which tend to limit its use under some conditions. Satisfactory application of the coating requires the use of relatively expensive and highly specialized electrically heated spray equipment. The present formula is somewhat difficult to apply at temperatures below 50° F. and should never be applied at temperatures below 30°F. There is also room for considerable improvement in the flexibility and adhesion of the present hot plastic, particularly in cold waters. The relatively low melting point of the paint is a disadvantage in a warm climate where direct rays of the sun may cause the coating to soften and sag before a vessel is undocked unless precautions are taken to hose the hull down with cool water. In order to obtain the best performance from hot plastic, a better quality bottom cleaning job is required than that used for the present commercial antifouling paints. Improved hot melt formulations now under extensive test should eliminate most of these deficiencies, but it is certain that specialized spray equipment, skilled labor, careful supervision and a relatively good job of bottom cleaning will always be required for satisfactory application of hot plastic paint.

Since hot plastic paint could not be used in very cold weather and in the absence of specialized spray equipment, a good quality solvent type antifouling paint was required by the Navy for use at advance bases, in small building yards and in northern yards during the winter. As a result "cold plastic" paint was developed to duplicate as far as possible the outstanding durability of hot plastic. Cold plastic is a brushable solvent type paint which has an effective life at least 3 times that of the old formula 15RC formulation. On ships this coating has given complete protection against fouling for 12 to 16 months. On test panels two coats of the paint have an effective life in excess of 24 months. The best of many commercial antifouling paints tested under identical conditions have failed in less than 8 months.

It is doubtful if an improved cold plastic or other solvent paint can ever equal the performance of hot plastic under practical conditions. At least 25-50 mils of hot plastic can be applied in a single coat as contrasted to maximum of about 6 mils of solvent type paint per coat. Since these paints must wear at the surface to continu-

ously expose active toxic, their service life is theoretically determined by the paint film thickness. Actually, at equal thickness solvent applied paint films tend to be more water permeable than hot melt films and may fail prematurely by blistering. Thus a better anticorrosive paint system is required for solvent type paints than for hot melt paints.

It is obvious that both hot melt and solvent type antifouling coatings have a place in the ship bottom paint field. Hot melt coatings are indicated where the ultimate in durability is required and where proper facilities for their application are available. Although intrinsically less durable than hot plastic, paints such as Navy cold plastic are much more effective than the average commercial antifouling paint available today. These paints can be applied with presently available dockyard spray equipment and without major changes in present docking procedure.

Millions of dollars are spent to obtain an extra knot from a naval vessel whose top speed may easily be reduced a much greater amount by marine fouling. Obviously the maintenance of top speed and maximum cruising radius is of such tremendous tactical importance that selection of an antifouling paint can be based entirely upon efficiency and not upon cost. Undeniably the present U. S. Navy antifouling paints are far superior to the proprietary paints used by commercial shipping companies. However, this fact alone does not necessarily guarantee that the Navy type of paints could be utilized economically in the commercial shipping field, if and when they are released for general use. Their intrinisically higher initial cost would have to be more than counterbalanced on a dollars and cents basis by increased operating efficiency. In the following sections of this paper an impartial analysis of the subject will be attempted.

Commercial ship bottom painting practice has generally been based upon a one-day docking schedule. In a typical case the vessel is docked in the early morning and the bottom superficially cleaned of fouling, corrosion products and loose paint with long handle hoe scrappers. Little care is exercised in the cleaning operation and the surface is usually in poor condition for repainting. A single coat of anticorrosive is applied and rapidly followed with a coat of antifouling paint. The vessel is then undocked late the same day.

Ship cleaning and painting contracts are frequently awarded at a unit price per gallon of paint applied. It has been observed that in many commercial docks paint is sprayed on ship bottoms by use of a 10-or-15-foot length of pipe flattened at the discharge end to provide a crude spray fan. When such spray equipment is used, the bottom paint is frequently a mass of runs and sags with many icicles of paint hanging from the plate laps and many gallons of excess paint in pools on the dock floor. Obviously such painting procedure leaves much to be desired and is not conductive to satisfactory paint performance.

In an effort to obtain valid and representative costs for the docking and painting of commercial vessels, a number of shipping companies in the San Francisco Bay Area were contacted by the authors. These companies were very cooperative and readily supplied the desired data. Table I lists the various charges incurred in docking, cleaning and painting an 18,000-ton passenger liner in the San Francisco Bay Area immediately prior to the war. This ship was docked on a one-day schedule and received what is considered to be an average commercial bottom paint job.

The docking procedures and paint application techniques of the Navy have been selected primarily to obtain optimum bottom paint performance. Hulls are generally wet sandblasted to obtain the best possible surface upon which to paint. This process removes all old paint, scale, corrosion products and fouling growth.

The wet sandblasting process developed by the Navy differs from the common dry sandblasting process in that a slurry of wet sand is used as the cutting agent. Very little sand or dust spreads from the immediate blasting area. The spent sand and

blasting byproducts are eliminated in the form of a mud which is washed from the work during the blasting. Either wet or dry sand may be fed to the blasting machine. Superficial corrosion of the freshly blasted bright metal surface can be controlled by adding chromate inhibitors to the wet sandblast slurry or by applying phosphoric acid painting pretreatments after the blasting operation.

After cleaning the hull, two coats of anticorrosive are applied with conventional paint spray equipment. A minimum drying time of 2 hours is normally allowed before the antifouling paint is applied. Navy hot plastic, formula 15 HP, is melted and raised to 300°F. in large reducing kettles. The molten paint is transferred to special electrically heated pressure spray kettles equipped with electrically heated spray hoses and spray guns. A 0.030 inch film of hot plastic is rapidly applied in a single coat with this equipment.

Navy cold plastic paint, formula 143, can be easily applied by either brush or conventional paint spray equipment. A film averaging about 0.005 inches thick is normally obtained in a single coat. Whenever time permits, a second or even third coat of cold plastic is applied to obtain a thicker, more water impermeable and durable paint system.

Cost estimates for application of the Navy hot and cold plastic paint systems to the previously described 18,000-ton vessel are listed in Tables II and III. These cost analyses are based upon labor and material records obtained from the Naval Shipyard, Mare Island, California, the United Engineering Co., Ltd., Alameda, California, and the Kaiser Company, Shipyard No. 3, Richmond, California. During the course of the war these shipyards applied hot and cold plastic antifouling paints to many vessels of the U. S. Navy.

The paint costs assumed in this study are estimates of what comparable products could be sold for on the commercial market. The contractor's profit for sandblasting and cleaning has been estimated at 15 per

TABLE VI

PROPOSED DOCKING INTERVALS FOR COMMERCIAL SHIPS

Paint	Passenger Ships	Freighters
Present Commercial	9 Months	12 Months
Cold plastic	15 Months	18 Months
Hot plastic	24 Months	30 Months

TABLE VII

DIRECT DOCKING COSTS OVER A 72-MONTH PERIOD

Paint	Number of Dockings in 72 months	Cost of One Docking	Docking Costs for 72 months	Docking Cost per Year
Hot plastic	3	$7,688.16	$23,064.48	$3,844.08
Cold plastic	5	5,552.80	27,779.00	4,629.83
Commercial	8	4,409.50	35,276.00	5,879.33

cent of direct labor and overhead. The commercial dock charges are the same as those used in Table I.

The high cost of the standard Navy plastic paint applications would in all probability restrict their use by commercial shipping operators. Anaylsis of Tables II and III show that these high costs result largely from the sandblast cleaning operation and from the long and expensive docking interval. The Navy has considered sandblasting necessary to assure optimum paint performance. Due to war conditions, vessels could seldom be docked at regular intervals, although most of the Pacific fleet operations were in waters of high fouling intensity. The complete elimination of fouling for periods up to two years was considered to be of paramount importance in order to avoid unacceptable losses in top speed and cruising radius. The Navy antifouling paints and painting procedures achieved this goal and fouling never restricted fleet operations. It must be emphasized, however, these same conditions do not apply to commercial ship operation, where any extra expenditure for painting must be justified on an economic rather than strategic basis.

It is the conviction of the authors that commercial operators, who can set definite drydocking intervals for their ships, can dispense with regular sand blast cleaning without seriously reducing the service life of the Navy type of bottom paints. There have been many cases where Navy hot plastic paint has been applied to ships which were not sandblasted, and these applications have given excellent service for periods ranging up to 30 months. In fact, the outstanding durability of hot plastic was conclusively established during the late thirties by ship service applications on vessels which had been superficially cleaned with hoe scrapers and wire brushes.

If sandblast cleaning is eliminated, the cost of a standard Navy plastic application is greatly reduced and the time in dock is appreciably shortened. While it is believed that sandblasting could be eliminated as a regular procedure, it would always be desirable to sandblast hulls which were in very poor condition. At subsequent

dockings sandblast cleaning would not be required and the cost of the initial operation would be more than repaid by improvement in paint performance and reduction in hull corrosion over a period of several years.

When the Navy type of antifouling coatings are applied over old paint, only a single coat of anticorrosive is required. The primary function of the anticorrosive in such a case is to improve the adhesion of the antifouling coating. Elimination of the second coat of anticorrosive obviously lowers the cost and time required for a bottom paint application.

The estimated costs for application of hot and cold plastic paints to the previously described 18,000-ton vessel are listed in Tables IV and V. Sandblasting has been replaced by the commercial type of bottom cleaning and the use of single coat of anticorrosive paint has been assumed.

Bottom painting is not the only factor which determines the drydocking interval of a ship. The underwater fittings, bearings, overboard discharges and legal requirements as to the pulling of tail shafts must be considered. A ship must be drydocked at least once every 3 years for pulling and inspection of the tail shafts. The time that the other underwater fittings can go without inspection or repair is usually governed by the quality of materials used. Lignum vitae or micarta bearings should give satisfactory service for 5 years. Sea valves should give satisfactory service for 24-30 months. Based upon these data and the established service records of the Navy paints, commercial operators could safely increase their drydocking intervals by adoption of the Table IV or V bottom paint systems. It is believed that the docking intervals for hot and cold plastic paints proposed in Table VI below are conservative and entirely practical. The present average docking interval of commercial ships has been included for comparison.

A comparison of docking costs over a 72-month period for the Navy plastics and present commercial ship bottom paints has been prepared in Table VII, using the docking intervals proposed in Table VI and the docking costs of Tables I, IV and V.

It is indicated, therefore, that substantial savings in direct docking charges would result from use of either the Navy hot or cold plastic paints by commercial shipping operators. In addition, several other savings and benefits would accrue from use of these effective paints. The decreased frequency of drydocking would result in considerably less time lost in dock and would simplify ship operation. Corrosion of the shell plating should be materially reduced from what is encountered at present.

Matson steamer Mahukona—after cleaning.

As far as can be determined, fouling on commercial ships, at the present time, is controlled more by operating conditions and frequent drydockings than by any action of the bottom paints. With present drydocking schedules, active ships generally foul rather lightly while inactive ships almost invariably foul very heavily. Most active commercial ships appear to suffer a 5 to 10 per cent loss in operating efficiency from fouling after 9 months out of dock. Much higher losses are encountered with ships which spend considerable time in harbors. Use of the Navy type of antifouling paints should completely eliminate the fouling of commercial ships and result in substantial increases in operating efficiency. The potential savings from elimination of fouling cannot be accurately estimated, but they undoubtedly would be very large.

During the war period many commercial dockyards were equipped with hot plastic spray equipment. These yards painted hundreds of naval vessels with hot and cold plastic paints. Therefore suitable equipment and trained personnel for application of the Navy type of antifouling paints are already available in commercial dockyards.

The formulas for the Navy hot and cold plastic paints were naturally considered important war secrets. These compositions are still classified as confidential by the Navy Department and consequently are not available for use on commercial ships at this time. The authors have no knowledge regarding the possible declassification of the Navy plastic paints for commercial use, but consider such action a distinct possibility.

Heavy Tools at Hunters Point

By Frank A. Stanley

Fig. 1: The two original docks, huge machine shop and parking lot.

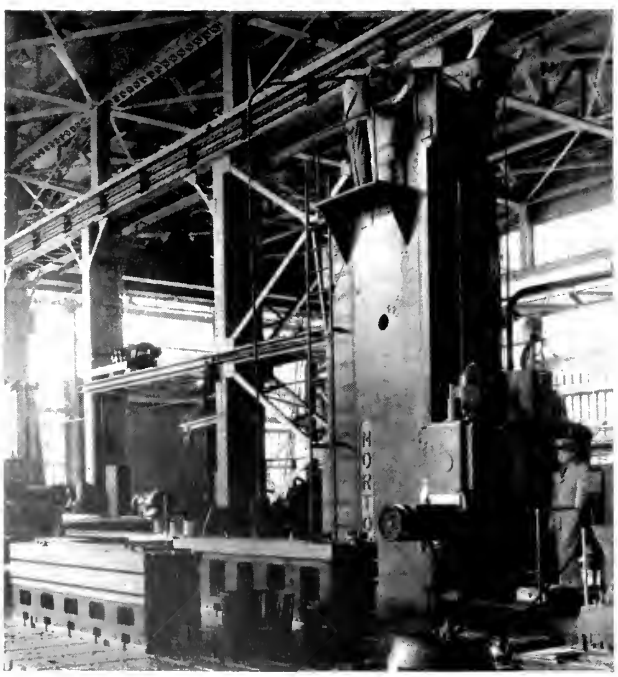

Fig. 2: World's largest size boring, milling and draw cut machine.
(U. S. Navy Official Photograph.)

The main machine shop at the U. S. Naval Dry Docks at Hunters Point, San Francisco Bay, is provided with facilities for overhaul and repair of machinery and equipment from all classes of ships and craft of the Navy. The shop structure is a two story building 600 feet in length by 170 feet wide equipped throughout with modern tools occupying all available floor space on main and upper floors. Among the machines on the main floor are some of the most massive and largest capacity tools ever constructed by their builders. The complete installation is adapted to the performance of standard and special operations in the way of drilling, turning and boring, planing, milling, grinding and other machine work on an apparently unlimited variety of undertakings related to the class of

(Frank A. Stanley is long-time editor of Western Machinery and Steel World and co-author of American Machinists' Handbook, and author or co-author of 20 or more books on mechanical subjects.)

jobs necessitated by naval machinery repair and maintenance.

An excellent general view of the exterior of the great machine shop is reproduced here in Fig. 1, where it will be seen in the right distance, with the two original dry docks at the left and the liberal parking area in the foreground. Without entering into specific details of the docking facilities in this article, it will be of interest to note that under the great expansion program which has been carried out at Hunters Point there is now a total of six docks with a combined capacity greater than the entire graving dock capacity of the Pacific Coast pre-war. Its No. 4 dock will accommodate any ship afloat, whether naval or mercantile, and No. 3 dock will take all such ships, with one or two exceptions. These facts regarding docking facilities and a wealth of other pertinent information regarding Hunters Point are contained in a feature article in the October 1945, issue.

It is the purpose in this present story to confine details largely to machine tool equipment of the shops. In all some 800 or more important tools are included in the machining facilities for large, medium and smaller work, as handled here.

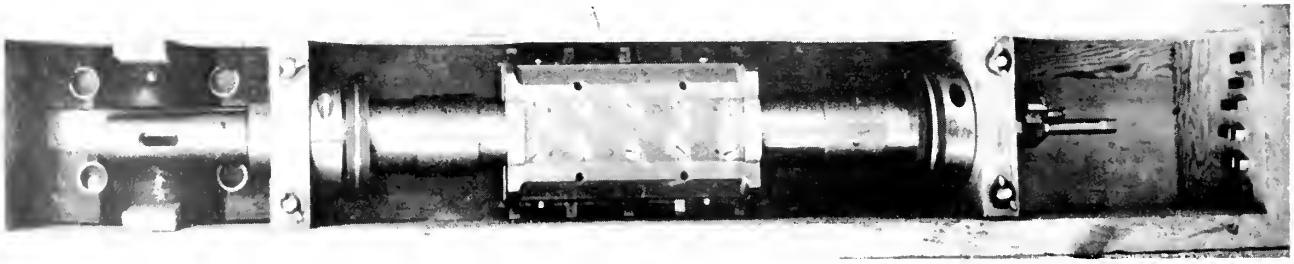
Mammoth Draw-cut Machine

The latest big machine tool to be installed in the main shop and the largest design of its type is illustrated in Figs. 2 and 3. This is a Morton boring, milling and draw-cut machine whose installation was completed the early part of November last, or some four months ago. It is known officially as a 96-inch horizontal boring, drilling and milling machine and draw-cut traveling head planer, and is an outgrowth or development of the well-known Morton draw-cut shaper so familiar to railroad shop machinists and Navy Yard craftsmen.

This machine, universal in its flexibility, was built with one other of precisely the same dimensions for machining heavy armor plate in an Eastern steel mill. Both machines were provided with 36-foot base plates or beds proper for the horizontal travel of the massive upright column or housing for the vertically adjustable saddle, in which is mounted the draw-cut planing ram and boring bar and operating mechanism. It was decided to divert one of these machines to Hunters Point, and the excessive bed length being considered unnecessary for marine shop activities the bed was cut in two, or to an over-all length of 18 feet, which is now the maximum length of horizontal feed for the machine illustrated here.

Consider a few major dimensions of this draw-cut unit. The ram which does the work of planing is 15″ x 15″ in section and has a maximum cutting stroke of 96″ and an extreme length of stroke of 108″. It handles an 8″ boring bar, and an outboard housing for mounting on the big floor plate converts the draw-cut into a large

Fig. 10: Boring bar with multiple cutters for pump casing.



capacity horizontal boring machine. In Fig. 2 the ram is seen with a large inserted tooth face milling cutter mounted on an arbor carried in the ram. Face milling with such a cutter is one of the typical operations to which this machine is adapted. The height of the machine may be estimated by comparing it with the person standing on the operating platform at the right of the column. This is Lt. J. D. Stoddard, Machine Tool and Shop Facilities Officer, whose many courtesies and assistance in connection with the gathering of material for this article are here gratefully acknowledged.

Wide Range of Operations

The shaping or planing head is shown removed in Fig. 2 to permit the application of the face mill. In place, the head carries planing tools 2″ x 2½″ in size, and the hand feed of the tool head is 12″. Another entirely different type of work is shown in Fig. 3, where the ram is shown fitted with a head for carrying an end mill or drill, an obvious convenience when a relatively small job is to be performed at some very difficult point on a large piece of work.

In this instance the mill is at work cutting T-slots in a section of the big floor plate which is being installed at the front of the draw-cut for all classes of heavy jobs that may be required to be machined here. These sections are cast blocks 6 feet by 12 feet in area and about 12″ thick and the T-slots enable the outboard support for the boring bar to be situated wherever required as well as allowing work of all kinds to be set up and properly secured.

Spaced a few feet apart will be noticed across the floor plate a number of groups each of three counterbored holes. These represent the seats of as many adjusting jack screws and hold-down bolts and nuts by which the big sectional floor plate may always be kept truly level. The counterbored seats are sufficiently large in diameter to provide ample clearance for the special socket wrenches used on the screws and nuts. The T-slots cut in the bed are sized for 1¼ inch bolts.

The main drive motor for this machine is 20 horsepower and the feed motor is 7½ horsepower. The machine stands above the floor plate a height of 22 feet 6 inches. To people unfamiliar with the cost of modern, large capacity, heavy machine tools, an item of interest will be the statement that the draw-cut machine here described represents—with various appurtenances not included in the views—an outlay closely approximating $350,000.

Convertible Openside Planer

Turning now to another class of heavy tools, let us refer to Fig. 4 and the Cincinnati convertible openside Hypro planer there illustrated. This planer is rated as a 132-inch machine with a maximum height under the rail of 96 inches. The left-hand housing can be removed when work wider than the planer's regular capacity is to be machined. The housing can also be adjusted to slide on its base to bring it close to the bed when so desired in order to make full use of the left-hand-side head. This is a particularly valuable detail when handling certain classes of work in the same manner in which machining would be done with a conventional two-housing planer.

The planer has also a supplemental rolling table to take care of any size job regardless of width. At the time this photograph was made two long steel bars were being finished on the regular planer table; they do not in any way suggest the very heavy jobs the machine is adapted to handle, but do emphasize the fact that in any maintenance plant the hurry-up work that comes in has to be taken care of in the first available machine which may be standing open at the moment on the shop floor.

This Hypro planer has a 36-foot table and a bed 80 feet long. The main drive consists of a 75-horsepower direct current reversing motor combined with a motor-generator set—a 125-horsepower unit operating under 440 volt, 3 phase, 60 cycle alternating current. This motor-generator set will be seen in Fig. 4 installed in the overhead structure near the center background of the photograph.

Normally the type of drive provided with this maker's planers gives a range of cutting and return speeds from 8 to 240 feet per minute. Wide experience of the company with machining of various kinds of metal has led them to definite recommendations as to roughing and finishing speeds for planing. Some of the data they have developed in connection with the operation of their variable

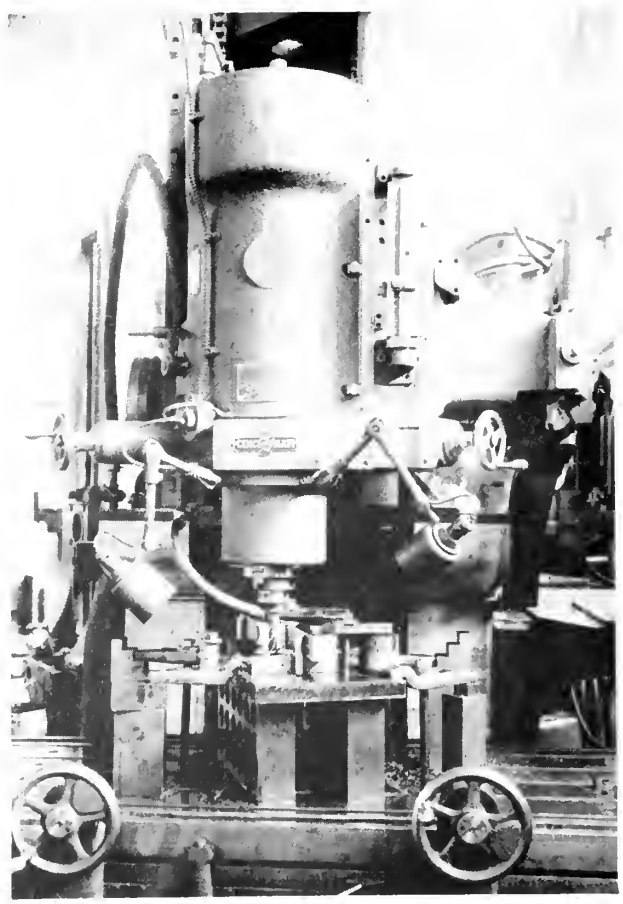


Fig. 11: Cincinnati Hydro-tel milling machine.

speed planer drives have aided in establishing standard practice in respect to both cutting and return rates, particularly on large and medium-sized work.

Big Vertical Boring Mill Capacity

Another type of big machine tool is illustrated in Figs. 5 and 6. This is a Sellers vertical boring and turning mill with table 20 feet in diameter. Here again the work under way at the time of making these photographs does not do justice to the spectacular proportions and capacity of the machine itself. Note the massive columns, arch and cross rail with the long tool rams and their long range of travel when the rail is elevated to extreme height.

The work shown in Fig. 5 is a simple boring and facing operation accomplished with the two tools in simultaneous action, one fed downward by its ram for boring, the other fed crosswise by the ram traveling on the rail. The job in Fig. 6 consists of facing a pair of heavy brackets or angles forming part of a special table for one of the big machine tools. The two angle castings are secured to a central support and are finish faced on their upper working surfaces by rotation under the two cutting tools in the rams, one set for roughing, the other for taking a finish cut by following up the lead of the roughing tool. The angle castings measure 6 feet by 3 feet across the working surface.

A row of Hypro vertical boring mills is illustrated in Fig. 7. These range up to large capacity in diameter of table and height under rail in uppermost position. The piece of work seen in the second machine in the row is a bronze sleeve which is chucked in the table jaws for boring to diameter and facing off to length.

A Long Bed Lathe

The 60-inch lathe in Fig. 8 is a Betts-Bridgeford tool, designed as a turning and boring lathe for long work, as a gun barrel lathe, or as used here for turning and handling long propeller shafts. It swings between centers work 60 feet long and its 150-foot bed fits it for boring work 60 feet in length. The job in the lathe is an 18-inch destroyer shaft which has had its bearings built up by the metal spraying process, and the work under way here is the finishing of the sprayed surface to diameter. The long shaft section is centered at the coupling end by the chuck jaws and supported at the outer end in the big steady rest. The turning tool is immediately behind the supporting rest.

Work of this character has of course to be centered carefully at the outer end before setting up the steady rest jaws. A portion of the smoothly finished bearing surface will be noticed directly behind the ends of the jaws. This practice of rebuilding and refinishing shaft bearings by metal spraying is a common one today, particularly in marine shops. It must necessarily be carried out with proper attention to preparatory operations, and after building up, the surface must be machined with due care in respect to the use of the finishing tools.

The surface to be built up must be clean and rough, and is often prepared by using a lathe tool which will produce what appears like a roughly threaded job; or the shaft can be sand blasted or steel grit blasted to give a rough surface. In any case, the purpose is to provide a surface to which the sprayed metal will be keyed or bonded securely as it is melted in the flame of the gun and shot against the work. The effect is to produce a sleeve of new metal which can be refinished to size by turning or grinding.

If a lathe tool is employed the cut should be light and the feed equally so in order to avoid all possibility of tearing the bonded metal loose from the parent surface. In fact, much of the work of this class is finished by the grinding process, and in the shop under description here a specially designed Dumore grinding attachment has been built for application to shafts of this size as well as smaller ones, the work being handled according to size in certain lathes arranged for the purpose.

Another big machine soon to be installed in the same section with the large tools already described is a lathe from Meata Machine Company, who had started to build a 36″ mortar designed for use against the Japs when the end of the war brought this project to an end. The mortar was designed to fire a missle weighing two tons. Although of large caliber the mortar was relatively short and the lathe intended for turning and boring was designed for 60 feet between centers and had a swing of 110 inches. To adapt the machine especially to the requirements of the Hunters Point shop, raising blocks supplied will increase its swing to 132 inches.

Other Lines of Operations

A few more operations, these on machines of more moderate capacity, are illustrated in the views which follow. Thus in Fig. 9 a high pressure pump casing is shown in the process of being roughed out on a Universal boring, drilling and milling machine. This casing, divided in halves along the longitudinal center, is a pair of steel castings which have been built up over all worn places by tough alloy electrode application to dimensions sufficient for machining back to original size. This tough weld metal is machined by single point tool, and time and patience are required in handling the work.

The boring bar, Fig. 10, is used in a following operation in a horizontal boring machine for roughing and finishing the interior for the impellers, with five cutting tools working at once in as many annular channels which have to be definite width and depth. Two sets of square stock tools are located in the body of the boring bar; five roughers adapted to be fed out automatically from one side of the central location and five finishing cutters directly opposite in the body of the bar. The latter tools are retracted during the time the roughing tools are at work, and upon withdrawal of the roughing cutters the finishing tools are fed out radially to complete the grooving operation.

During the channel operation the boring bar is mounted in the impeller bearing seats and is thus in truly central position. An ingeniously arranged register at the outer end of the bar gives the operator an accurate indication of the depth to which the tools are fed in to the work.

Vertical Hydro-tel Milling Machine

A Cincinnati vertical Hydro-tel miller with hydraulic automatic depth control is represented in Fig. 11. Longitudinal travel of the table, cross travel of the cross slide and vertical travel of the head provide a three-dimensional combination of movements adapting the milling ma-

chine to handling any class of work in the line of dies or other intricate shapes. With the automatic control copying can be done from a master or a template.

The illustration shows the set-up for producing a cam-shaped bucking bar for the sheet metal shop, this being a heavy piece of steel about 2 inches square with peculiar offsets for convenience of handling and applying to the work.

In this instance the copying is done from a template secured to a bracket at the extreme right of the photograph.

The work piece is about 18" long and is secured crosswise to the longitudinal table. The actual milling to shape is accomplished by cross travel of the cross slide.

All movements, longitudinal, cross and vertical, are actuated hydraulically, and all controls are so located as to be most conveniently handled by the operator. This is brought out clearly in the photograph. The method of holding the work is seen with the supporting plate in the immediate foreground, and the helical tooth mill will be noticed in actual cutting operation upon the edge of the work.

Some Balancing Operations

Two Gisholt Dynetric balancing machines are illustrated in Figs. 12 and 13. The first of these half-tones shows a large machine with reversible propeller in place for balancing. The other machine is shown balancing a ship's blower unit. These are only two sizes in the above company's regular line of balancing outfits, which in total cover a range of work from parts weighing as little as a fraction of a pound up to a piece weighing several tons.

The requirement of higher speeds in modern equipment, the demand for noiseless operation free from vibration, and the desire to cut down maintenance delays and troubles, are among the reasons why proper balancing of many classes of parts is essential today.

Unbalance may be due to a number of factors, such as lack of concentricity of the part; lack of homogeneity in materials; lack of uniformity or squareness of the work about its axis, due perhaps to improper machining operations; or to one of a number of other causes. In any event correct balancing of rotating parts has become of utmost importance.

The elimination of vibration due to unbalance is accomplished by application of corrections which may be in the form of weights added to the body or material removed from the body. These machines locate and measure the amount of unbalance in rotating parts with great accuracy.

Large Cargo Carrier for A. P. Lines

S.S. Marine Leopard Runs Successful Sea Trials

The S. S. Marine Leopard, a U. S. Maritime Commission Type C-4-S-A-4 cargo vessel, ran successful trials on February 8, 1946, and was delivered to the American President Lines.

This type of vessel was described in the November issue of Pacific Marine Review when the drawings of the profile, general arrangements, and midship construction section were also published.

She was originally constructed as a C-4 troop transport, one of the 35 built at Yard No. 3, Richmond, California, by the Kaiser Company Inc. Since the end of August, 1945, in the process of reconversion she has undergone removal of an estimated 700 tons in miscellaneous bulkheads, deckhouses, gun emplacements, machinery, and other defense features, as well as changes from troop accom-

modations for 4209 persons to cargo space.

The following is a list of her main particulars:

Length	522 feet 10 inches
Beam	71 feet 6 inches
Depth	43 feet 6 inches
Draft (loaded)	32 feet 0 inches
Horsepower	9,000
Speed	18 knots
Total Displacement	19,850 tons
Deadweight	13,096 tons
Lightweight	6,754 tons
General Cargo	10,493 tons
Wet Cargo	836 tons
Dry Cargo	9,284 tons
Refrigerated Cargo	373 tons
Complement	58
Keel laid	May 17, 1945
Days in Basin	71
Launched	July 27, 1945
Ordered Converted	Aug. 12, 1945

New C-4's at Portland

A series of trial runs by the C-4 class of ships being built in Portland-Vancouver area started at Portland in January when the SS Louis McHenry Howe, built at Kaiser's Vancouver shipyard, ran her trial. This is the largest general cargo type built during the war period. Her main house is forward and engine compartment is aft. When one-half of an ordinary shipload of lumber is carried on her main decks the cargo capacity is some 14,500 tons. When she was laid down on the ways last spring, the Howe was scheduled to be a troop carrier with berths for about 3500 men, but the sudden end of the war caused this vessel and seven other hulls to be converted into peace time cargo carriers of a new class. The Howe is scheduled to go into intercoastal service with the Luckenbach S. S. Company if her trials proved her as good a ship as her builders believe. New features incorporated in the Howe are steam schooner type of rigs with special remote-controlled topping lift winches and three-section hatch covers for quick handling, and vertical battens in the holds to increase capacity and decrease damage claims. The Howe has seven large holds. No. 3 hold has four 400-ton cargo oil tanks, with special heating and cleaning systems. No. 7 hold is fully refrigerated. The power plant is a 900-hp double-reduction turbine.

37,778 Ships Handled By Bethlehem During War

FOUR LARGEST ALLIED TRANSPORTS ARMED AND CONVERTED

The Queen Elizabeth, Queen Mary, Aquitania and Mauretania, the four largest ships available to the Allies as troop transports after the burning of the Normandie, were all armed and converted by Bethlehem Steel Company in New York Harbor.

Lifting the veil of security which shrouded many phases of its wartime activities, the company has disclosed that it handled a record total of 37,778 ships during the war years. Aggregating 302,224,000 dw tons, this armada represented a tonnage more than five times as great as the world's pre-war merchant fleet and more than 25 times the size of the American merchant marine in 1939.

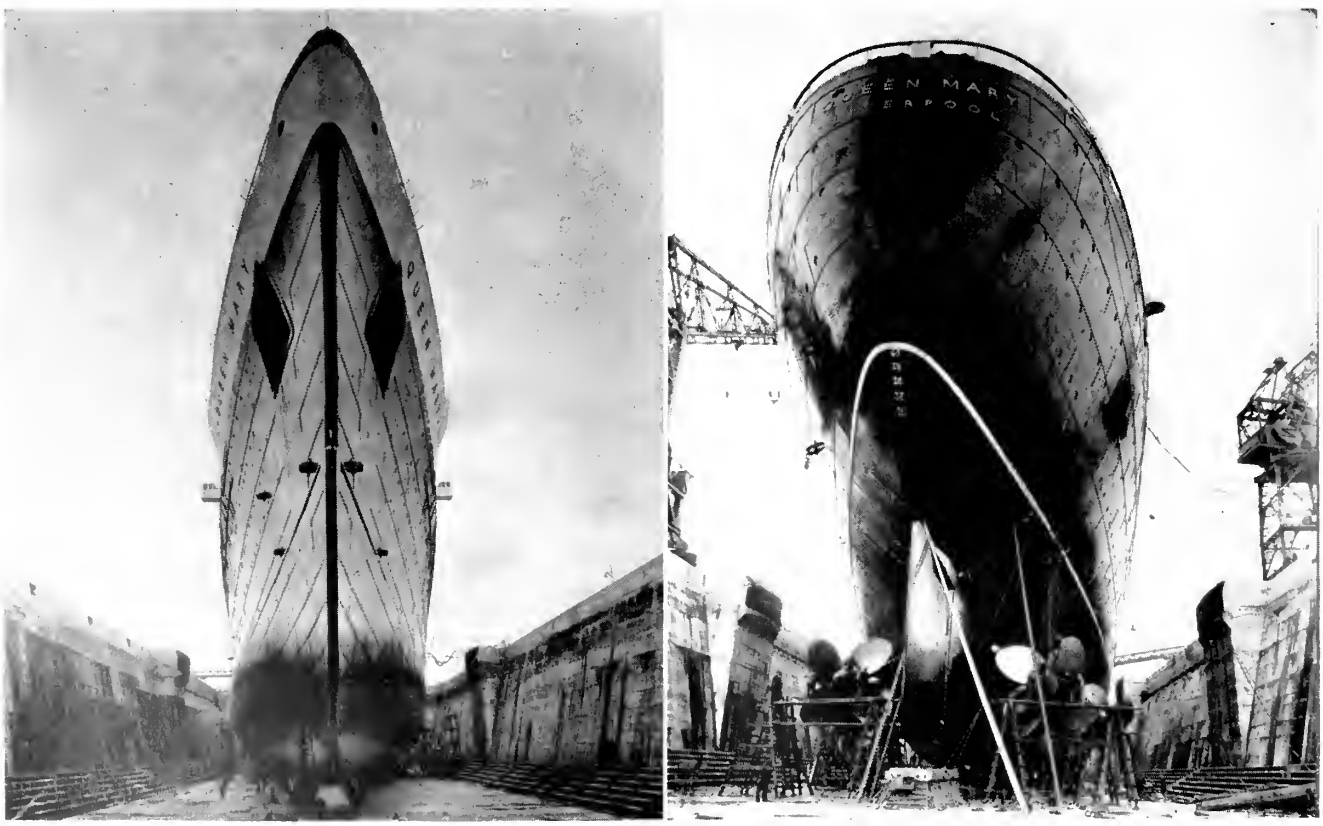
Ships of virtually every type afloat were handled, including battleships, aircraft carriers, submarines and other warships, in addition to merchantmen.

The four largest Allied transports were among 16 of the world's largest troopships which were regularly assigned to Bethlehem yards for repair and servicing from shortly after Pearl Harbor to the surrender of Japan. Other ships on the "regular list" were: Pasteur, Britannic, Andes, Orion, Argentina, Brazil, Uruguay, Franconia, Scythia, Samaria, Mariposa and Monterey.

Conservative estimates are that these 16 vessels transported more than one-third of all the troops moved from America to the war zones. The Queen Mary and Elizabeth alone were reported to have moved some 800,000 American troops to Europe. The Mariposa and Monterey, crack Matson liners, were among the largest carriers of U. S. personnel to the Pacific theater.

The urgent need for these large troopers necessitated special planning for their maintenance. They were

Queen Mary—Bow and stern views in drydock.



boarded by a Bethlehem representative at the conclusion of each voyage, even before they had completed docking. Together with officials of the shipping company, work was surveyed and laid out on the basis of the ship's sailing date.

So efficient was this method that not a single big ship under Bethlehem's care ever missed a departure date or broke down at sea.

With a rated speed too high for convoy, the 81,225-ton Queen Mary was armed with 33 guns, including one six-incher; 12 rocket projectors; one range finder; and one central gun control house. In addition, the big vessel was completely degaussed to protect her from the mine menace. Concrete and steel emplacements were built for the armament.

Conversion of the 975-foot vessel, a veritable floating seven-story hotel, was completed in three weeks, or in less than one-third the time originally estimated. The luxuriously-appointed dining saloon, built to feed 500 passengers at a sitting, was converted to a mess hall at which 2000 troops could be fed at a time. Troop quarters, galleys, recreation areas, hospitals were fashioned out of swimming pools, cabin spaces, etc. De luxe one-bed staterooms were converted into 12-bunk troop cabins.

Bethlehem also reconditioned the vessel's propulsion machinery, the first time that job had been done in the United States.

The 83,673-ton Queen Elizabeth, largest vessel in the world, was armed similar to the Queen Mary, with the exception of one 20-mm gun. She also was degaussed and converted by Bethlehem.

Biggest job on the liner came when she suffered heavy sea damage. Following one of the worst Atlantic gales in years, the big ship arrived here with her forward deck smashed down 14 inches, and heavy superstructure damage. It was originally estimated that repairs would take three months but the job was completed in less than a month.

Slated for the scrap heap before the war broke out, the 44,786-ton Aquitania also was pressed into service as a troop transport. The one-time "Mistress of the Seas" had been built before World War I, however, and one of the biggest reconditioning jobs of the war was necessary to put her into proper operating condition. The ship's turbines, the largest direct-drive marine engines in the world, were disassembled, renovated and cleaned, and then reassembled. Her boilers required virtual rebuilding and into them went 36 miles of 2-inch piping. Some of the decks were almost rebuilt. The Aquitania, because of her lower speed, carried two six-inch guns, in addition to 27 other guns, 17 of which were installed by the British and 12 by Bethlehem. Bethlehem also armed the ship with four rocket projectors and installed a central gun control house.

Completed just before Germany marched on Poland, the 35,677-ton Mauretania, which replaced an older Cunarder bearing the same name, also was brought to Bethlehem for arming and conversion.

One of the most spectacular repair jobs of the war was completed on this ship. At the height of the movement of troops for the North African invasion, the liner, loaded to the rails with American soldiers, was in a collision with another ship in New York Harbor. A survey showed that she had suffered heavy damage at the water line. Estimates were that the vessel could not be repaired sooner than from three to six days. Plans had already been made to disembark the troops when the Bethlehem representative promised to have the ship ready to sail in 24 hours. On that pledge, the troops were maintained on board.

In order to get the vessel to sea in the shortest possible time, it was decided to rivet huge plates over the damage. Plates of that type were not immediately available there so an emergency call was put through to one of Bethlehem's steel plants. Within a few hours the big plates arrived and selected riveting crews went to work. Twelve hours after the liner had limped back to her berth she was ready to sail again. The speed with which this job had been completed allowed the vessel to join a convoy she had been scheduled to make half a day earlier.

The emergency repair job stood up so well that permanent repairs were not made until six months later, when the troop movement to the European theater slackened.

San Francisco Port Engineers' Association

A group of San Francisco port engineers met on February 1 at El Jardin and took the initial steps in the organizing of a Port Engineers' Association.

The society, which is of a professional nature, is organized for the benefit of port engineers, and the main object of their association is the study of problems in the operation of the engine room department.

The officers of the society are Joe Gisler, port engineer of Interocean S. S. Corp., president; Frank Smith, port engineer of American Mail Line, vice president; and Charles Steel of Interocean S. S. Co., secretary.

Six-Star Admiral Has Six Ships

China's top admiral, Chen Shao-kwan, has six stars—one more than any other admiral in the world. He also has six small ships in his entire navy.

"What kind of sailors are they?" asked St. Peter.

"Yanks," replied the gatekeeper.

"Oh, let 'em in," said the Saint, "in six months they'll be asking for a transfer anyway."

F.-M. Opposed-Piston Two-Cycle Diesel

Some 10 years back Pacific Marine Review announced the first in a series of Fairbanks-Morse diesels built to a new and then very promising design. This was the opposed-piston two-cycle diesel with upper and lower crankshafts connected through bevel gearing by a splined vertical shaft. A number of these engines were in satisfactory operation when World War II came along and the Navy contracted for a group to drive various small auxiliary craft. Performance was so satisfactory that many more orders were received, and today there are now engines of this type developing about 3,000,000 shp in active service as marine, stationary and locomotive installations.

Cylinder Block

As shown in the cutaway views here, with the cylinder block is the main structural unit of the engine. This is a weldment, with all parts cut from steel plate and assembled on jigs by welding. This block has compartments for: the control end; the vertical shaft assembly; the upper and lower crankshafts; the camshafts and fuel pumps; the injection nozzles; the air receiver; and the exhaust manifold. The air receiver, vertical drive, and control end compartments are fitted with access covers. A sheet metal top cover is fitted with several small inspection holes with spring loaded covers. An oil pan closes the lower crankshaft compartment, and suitable large covers at the sides complete the closure.

Plate for this frame is cut into the various forms needed by automatic gas flame cutting machines. The pieces thus formed are assembled in small weldments and are then placed in a specially designed fixture which holds them rigidly in position while they are tack welded in place. The entire frame is then moved to a huge positioner where welding is completed.

As first designed there was a shrinkage of 1/8 inch to the foot during the welding process. Redesign reduced this shrinkage to 0.039 inches to the foot.

The frame is then sandblasted and Magnaflux tests made to check all vital points in the welding. It is then stress-relieved to remove the internal strains due to the welding process.

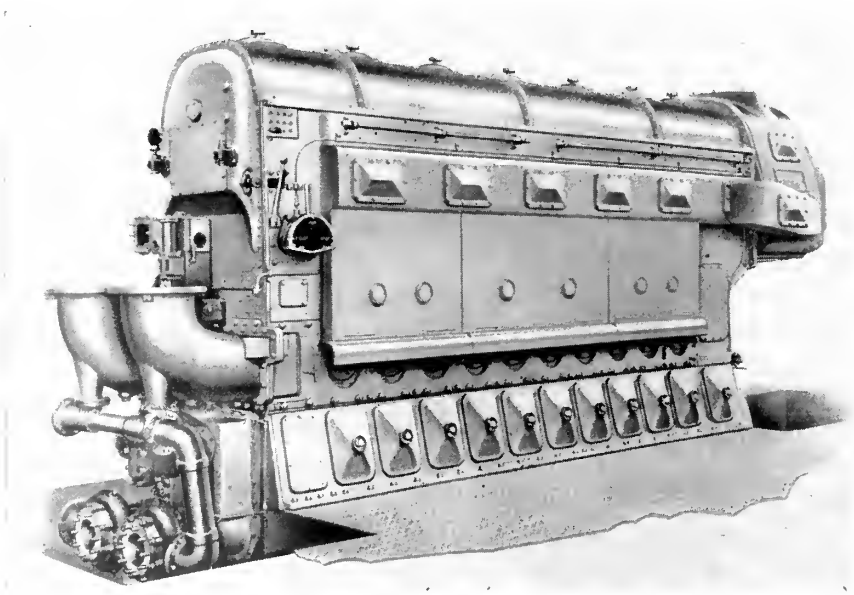
Cylinders

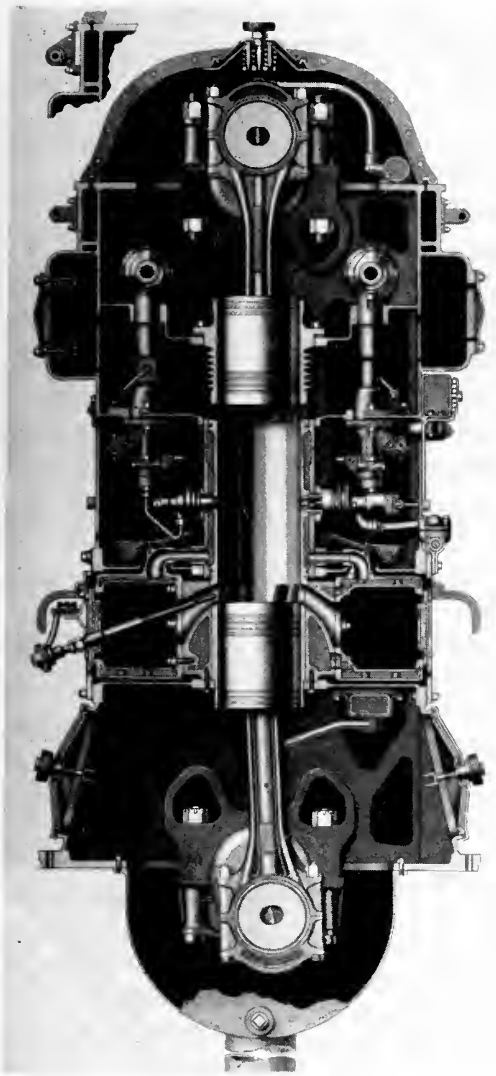
A close-grained cast iron of great tensile strength is used for the cylinders, which are bolted into the main frame along its center line, the holes being bored in accurate alignment with the crankshaft throws. Each cylinder is composed of a liner, a jacket, rubber rings, and a lock ring. The water jacket is rolled from steel plate and welded at the seam. After accurate machining it is hydraulically pressed onto the liner. The rubber rings act as a water seal and the lock ring prevents any movement of the jacket due to expansion. The circular ribs near top of liner act to help cool this part of the liner which is surrounded by scavenging air. The vertical ribs in the jacketed space act as guide vanes for, and present a larger radiating surface to, the action of the cooling water.

Piston Assembly

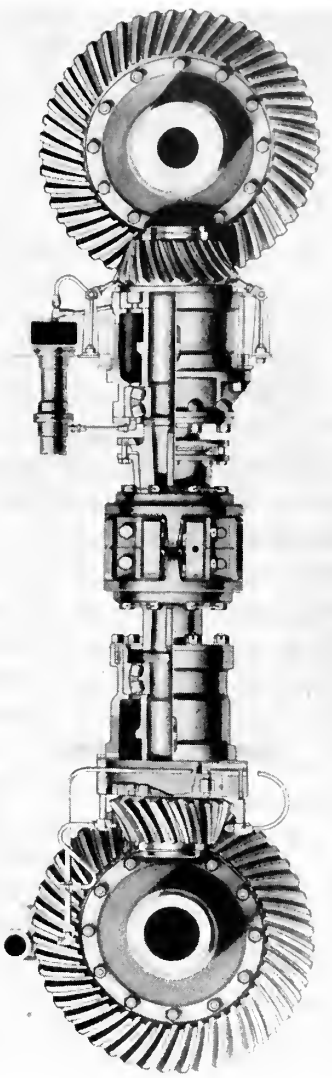
In this design there are no cylinder heads. The two pistons in each cylinder therefore have four basic functions: (1) to act as movable gas and compression tight closures; (2) to act as exhaust and scavenging air valves; (3) to form the combustion space at inner dead center; (4) to transmit the energy of the expansive forces to the connecting rods and crankshafts. Upper and lower piston and connecting rod design is similar, with the ex-

10-cylinder Model 38D8-1/8 O.P. diesel engine, control side.





Model 38D8-1/8 O.P. engine, cross section.



Model 38D8-1/8—8 1/8 x 10 O.P. engine, crankshaft vertical drive.

Connecting rod and piston parts, bronze bushing type 8 1/8 x 10 O.P. engine.

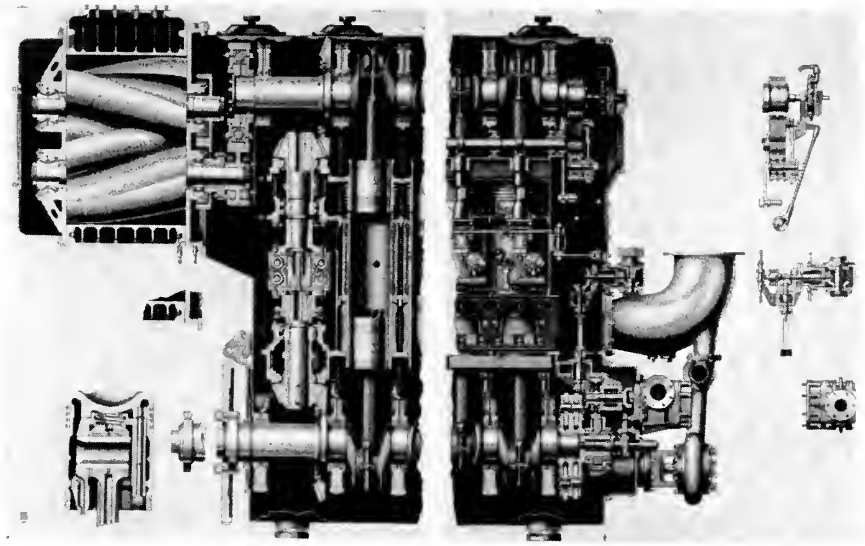
ception that the lower con-rod is 4 inches longer than the upper one.

The wrist pin is held in a separate bracket which fits into and is bolted to the cylinder so as to form an inner wall for the oil cooling jacket. Lube oil for the wrist pin bearing and cooling oil for the piston are both forced under the pressure system through drilled holes in the con-rods and into the wrist pin bearing and out into the piston cooling jacket, then out through a discharge-fitting into the crank cases, from which it drips down to a sump tank under the lower crankcase. This design gives an unbroken smooth cylindrical surface on the outer face of the piston, which is fitted with compression rings at its closed end and with oil control and oil drain rings at its open end.

Crankshaft Assembly

Crankshafts on this engine are of chrome - nickel - molybdenum alloy, precision machined to insure perfect wearing surfaces, and perfectly balanced. At its after end the upper shaft drives through spur gearing the scavenging air blower, and at its forward end, through sprocket chain, the camshafts. Power is taken off the after end of the lower crankshaft through a flexible coupling. At its forward end the lower shaft is fitted with a torsional damper to eliminate criticals. The gear for driving the governor and all attached pumps is keyed to the spider of this damper.

One of the novel features of this design is the vertical shaft assembly that connects the two crankshafts. This assembly is in three main parts, an upper and a lower vertical pinion shaft and the flexible coupling that connects them. Each pinion shaft runs in a large roller bearing next to its pinion and is supported by a substantial thrust bearing. The two halves of this shaft can be adjusted



Model 38D8-1/8 opposed piston engine.

to "time" the upper crankshaft properly in relation to the lower shaft.

Fuel Oil Supply

A fuel supply pump driven by gears from the lower crankshaft draws oil from the fuel service tank and delivers it through a strainer-filter to the engine inlet, building up and maintaining a pressure of around 15 psi in the fuel header, which is fitted with a regulating valve that by-passes back to the tank any excess oil. There are two injection pumps and two injection nozzles for each cylinder. The pumps are mounted vertically directly under the camshafts. They are of the constant stroke, single valve, rotating plunger type, the amount of oil delivered being dependent on the position of a helix machined on the plunger relative to the inlet port on the pump barrel. The angular position of this helix is adjustable through a rack and pinion mechanism controlled by the Woodward governor. Each pump is connected to its differential type, spring loaded, injection nozzle by a short (equal length for all pumps) section of high pressure tubing.

Cooling

Two pumps on the forward end circulate water, one fresh water, the other sea water. The fresh water is circulated through the cooling water jackets of the engine in a closed system that includes a heat exchanger. The salt water is circulated through this heat exchanger to cool the fresh water.

Scavenging

The scavenging blower of positive displacement type is mounted on the after end of the engine frame and supplies abundant quantities of 3 to 6 psi air to the air receiver compartment, which extends the full length of the frame and completely surrounds the tops of the cylinders at the upper port level. Thus, the air enters the cylinders under pressure and completely sweeps out the products of combustion through the lower ports and into the exhaust manifolds. Enough scavenge air remains in the cylinders to provide fresh air for the next compression stroke.

Starting is by air at 250 psi supplied to the cylinders through a header and spring loaded check valves in each cylinder. These valves are pneumatically opened by air from a distributor valve, controlled by a cam at the forward end of the upper crankshaft. A single lever at the control station governs the maneuvering positions. A second lever resets the emergency speed governor, and a push-button actuates the emergency stop.

The design is standardized around an 8 1/8 inch cylinder bore with 20 inch combined piston stroke. The normal speed is 750 rpm and the 10 cylinder size develops 1500 shp at that speed with 79.5 psi mep. The weight is approximately 25 pounds per shp and the over-all dimensions for 10 cylinders are: length 18′ 10 3/16″, width 4′ 7½″, and height, 9′ 8½″. The height above engine room floor required for removing cylinder liner is 8′ 7″.

New G. E. Industrial Electronics Training Course

An Industrial Electronics talking slidefilm training course which offers a thoroughly practical understanding of the subject of industrial electronics has been announced by the General Electric Company. This new course is expected to have wide use throughout the industrial and power company fields.

In industrial plants, the course should provide electrical personnel with sufficient theory and application information to acquaint them with electronics in general; production, design and process engineers as well as production managers and plant superintendents should obtain increased electrical knowledge and much stimulation, and should find that it offers innumerable practical suggestions and new ideas. The course is certain to provide new sales power to engineers with background necessary to deal helpfully with customers and for training their own sales staff.

Presented in a clear, non-technical manner, the course consists of 12 talking slidefilms (35-mm film strips and 16-inch, 33-1/3-rpm records) each approximately 30 minutes in length; 25 copies each of 12 lecture review booklets keyed to the slidefilms; and an instructor's manual covering the 12 lectures; and an attractive carrying case designed to accommodate the complete course.

Admiralty Decisions

By Harold S. Dobbs
of the San Francisco Bar

Bargeman Held to Be "Member of Crew"

For many years both the employer and underwriter have been plagued with the difficult task of determining in any given case whether injuries suffered by its personnel should be reported to the United States Employees' Compensation Commission and compensation paid according to the statutory schedule or, on the other hand, should be treated as a P & I[1] claim, assuming negligence is one of the factors. The decision is, of course, especially important from a dollars and cents liability standpoint. In the case of a true longshoreman's claim, namely one where the injury occurs upon navigable waters and the injured employee is **not** a member of the crew as defined by the Act,[2] the employer makes certain reports to the Compensation Commission and regular weekly compensation payments follow after the first seven days of disability. Of course there are many ramifications to the handling of these claims through the Commission which are too voluminous to discuss in the space provided. If the claim falls within the category of P & I claims, we have a vastly different problem. If the claim comes within this group we must assume that the injured employee was at the time of his injury a "member of the crew" and not a longshoreman, harborworker or similarly entitled maritime employee. It is this category, as previously mentioned, that gives the employer and underwriter so many sleepless nights. Litigated cases upon the subject have repeatedly and consistently required a strong and complete showing of facts upon which the court could say without fear of contradiction that the subject employee was a "member of the crew." With this background in mind, it is interesting to examine **Dillon's case** (1945 A.M.C. 1486, United States Cir. Ct. of Appeals, Third Circuit), where the court breaks away from the old standards previously discussed and announces a new liberal standard or measure for determining the definition of a member of a crew in any given case. Of course this case involves the question of the application of Section 3(a) (1) of the Longshoremen's and Harbor Workers' Compensation Act (33 U. S. Code sec. 903[a] [1]), in that it must be determined whether one Dillon was a "master or member of the crew" of the barge ARMY. The Deputy Commissioner found that ". . . Dillon was not a master or member of a crew . . . his status being that of a laborer or harbor worker . . ." and allowed compensation to his minor grandchildren. The pertinent findings of the Deputy Commissioner are as follows:

"(1) that on . . . (August 9, 1941, the day of death) and for about ten years prior thereto . . . Dillon had been employed on the barge ARMY as a caretaker . . .; (2) that it was the duty of Dillon when excessive leakage occurred, to attend to and to supervise the loading and unloading thereof, to fasten and unfasten lines as necessary and at all times to protect the barge from damage and otherwise safeguard the interest of its owner; (3) that his duties were limited to the barge ARMY; (4) that he was the only person employed thereon; (5) that he lived, ate and slept on the barge and bought his own meals; (6) that he was not a qualified or licensed seaman and held no seaman's papers; (7) that said barge had no motive power of its own and was towed by tug boats; (8) that its operations were confined principally to the Philadelphia harbor; (9) that the duties performed by the deceased employee prior to his death did not relate principally to the navigation of the said barge, but on the contrary his duties had substantially no relation to navigation, being principally the duties incident to common labor and custodial service . . .; (10) that . . . Dillon was not a master or member of a crew, within the meaning of section 3(a) (1) of the Longshoremen's Act, his status being that of a laborer or harbor worker . . ."

The District Court concluded that the Deputy Commissioner's finding that Dillon was not a master or member of a crew within the purview of Section 3(a) (1) of the Act ". . . is not supported by any evidence adduced before him and hence is not in accordance with law." The higher court continued by concluding that "on the contrary, the basic facts found by the Deputy Commissioner rightly call for the conclusion that Dillon was a member of a crew within the meaning of the . . . Act and therefore outside the scope of that Act."

It was held, therefore, that the Deputy Commissioner misconstrued the Act. As Mr. Justice Douglas stated in **Norton** v. **Warner Co.,** 321 U. S. at page 569, 1944 A.M.C. at page 341: "If the award were to stand, there would be brought within the Act a group of workers whom we do not believe Congress intended to include." The history of the Act was reviewed by the Supreme Court in **South Chicago Coal & Dock Co.** v. **Bassett,** 309 U. S. 251, 1940 A.M.C. 327, and in **Davis** v. **Department of Labor,** 317 U. S. 249, 1942 A.M.C. 1653. Nothing can be added by this court's opinion to those cogent recitals. The barge ARMY in the instant case is a vessel, despite the fact that it had no motive power of its own. It was a means of transportation on water. Dillon was on board the ARMY and aided in her navigation as the evidence demonstrates and the Deputy Commissioner found in his second finding of fact. Compare the facts in the **Bassett case,** 309 U. S. 251 at page 260, 1940 A.M.C. 327. The fact that the Deputy Commissioner concluded that Dillon was a caretaker is immaterial. He did take care of the barge but no one fact is conclusive. The purpose of the Longshoremen's and Harbor Workers' Compensation Act, as is pointed out in S. Rep. No. 973,

[1] Protection & Indemnity.
[2] Longshoremen's and Harbor Workers' Compensation Act.

69th Cong., 1st Sess., p. 16, was to provide compensation for persons ". . . mainly employed in loading, unloading, refitting, and repairing ships." These persons ordinarily are longshoremen and ship-fitters. Dillon was not such. He had some duties in respect to the loading and unloading of the ARMY. These duties, however, as the court below pointed out, were for the purpose of making sure that the loading or unloading of the barge was done in such a way that it would not be injured by excessive strain or capsized by unequal loads. In the court's opinion Dillon falls within the legal category of Rusin in the **Norton case** rather than in that of Schumann in the **Bassett case.** Accordingly the judgment of the court below is affirmed.

Removal Where Defendant Not Employee

Under the Jones Act, 41 Stat. 1007, 46 U.S.C., sec. 688, a seaman may sue his employer for personal injuries either in the state or federal courts. Experience has proved, however, that seamen and their counsel appreciate the benefits to be gained by trying their personal injury cases in state courts rather than under federal jurisdiction. It is, therefore, quite common to have the federal court remand to the state court any such case originally filed in the state court and removed by petition upon the ground that diversity of citizenship exists between the parties. In the interesting case of **Owen Steele v. American South African Line,** 1945 A.M.C. 1505, United States District Ct., No. Dist. of Calif., Sept. 19, 1945, a different result follows because the named defendant was not in fact the employer of the seaman and, therefore, was entitled to removal from the state court to the federal jurisdiction after alleging diversity and a claim exceeding $3000, even though the seaman had alleged a Jones Act situation.

In the **Steele case,** the plaintiff, a junior engineer of The S.S. CAPE BLANCO, moved to remand this cause to the state court, from whence defendant had previously caused its removal. The action is one to recover damages for personal injuries claimed to have been caused plaintiff on the CAPE BLANCO due to the negligence of defendant, whom plaintiff seeks to hold responsible as his employer at the time.

Removal of the cause to this court was accomplished on the ground that the claim of the plaintiff that defendant was his employer was colorable, if not fraudulent, and for the purpose of ousting federal jurisdiction. The removal petition asserted that plaintiff fraudulently alleged in his complaint that defendant was his employer in order to maintain the action in the state court pursuant to the Jones Act. The petition further alleged that in truth and fact, the defendant was not plaintiff's employer, and that consequently the cause was in reality a simple common-law action for negligence and therefore, because of diversity of citizenship, of federal cognizance. It was further charged in the petition that defendant was in fact the agent of the United States, the owner of the vessel. Such being the case it is asserted, the United States was plaintiff's employer and his cause, if any, based on the Jones Act, must therefore be litigated in this court, as provided in the suits in Admiralty Act, 46 U.S.C., sec. 741 et seq., and Public Law 17, 50 U.S.C., Appendix, sec. 1291.

In support of plaintiff's motion to remand, it is first urged that, in fact, defendant and not the United States was plaintiff's employer. However, by the "Service Agreement" between the defendant and the United States War Shipping Administration, the United States and not defendant was plaintiff's employer. This position has been firmly established by the following decisions of Judge Goodman: **Conlon v. Hammond Shipping Co., Ltd.,** 1944 A.M.C. 443, 55 F. Supp. 635; **Murray v. American Export Lines, Inc.,** 1943 A.M.C. 1426, 53 F. Supp. 861; **Baker v. Moore McCormack Lines,** 1944 A.M.C. 1248, 57 F. Supp. 207 (decision of Judge Roche).

It is next contended that at the time plaintiff signed on the CAPE BLANCO, he was unaware that the United States was the vessel's owner and that defendant held itself out as the vessel's owner-operator. Consequently it is urged that, on the basis of the well-known principle of the law of agency, i.e., that an agent may be held as a principal when the latter is undisclosed, defendant is suable as if it were in fact the employer. In support of this contention, plaintiff cites a decision of Judge Knox of the United States District Court (SDNY); **Lewis v. United States Navigation Co.,** 1944 A.M.C. 1241, 57 F .Supp. 652. That case, however, is distinguishable in several vital respects. Judge Knox found as a fact that the plaintiff Lewis was hired in the customary way through his maritime union by defendant shipping company and further that he was unaware that defendant, which had signed the shipping articles in its own name as "operating company," was acting as agent of the United States in servicing the ship and was without any authority over the vessel once she was on her way. Upon that theory, Judge Knox decided that plaintiff had a good cause of action against defendant under the Jones Act.

In the instant case, the Shipping Articles, signed by plaintiff, were executed by defendant as "Gen. Agts." Also attached to and a part of the Articles were certain regulations "pertaining to all American Flag vessels owned by or under bareboat charter to the War Shipping Administration." Hence plaintiff cannot here successfully maintain his position that he was in ignorance of the identity of his employer. Judge Goodman continues by stating:

"Moreover, I find myself unable to agree with the theory upon which the learned and experienced judge decided the **Lewis case.** The Jones Act fixes the rights and liabilities of seamen and their employers with respect to personal injuries suffered by seamen during their employment. It provides for the maintenance of actions by seamen against their employers. Sec. 33, Jones Act, 46 U. S. C., sec. 688. 'The statute is concerned with the relative rights and obligations of seamen and their employers arising out of personal injuries sustained by the former in the course of their employment.' **Panama R. R. Co. v. Johnson,** 264 U. S. 375, 387, 1924 A.M.C. 551. I cannot see how a cause of action specifically created by statute can be maintained against any party, other than the party statutorily charged with liability. Unawareness of the identity of the employer, at the time of signing on the vessel, is not, in my opinion, legally sufficient to fasten statutory liability upon a party not made responsible by the terms of the statute.

Coast COMMERCIAL CRAFT

Steel Welded Clipper Assembly Line

Steel welded tuna clippers are being built in a West Coast yard on an "assembly line" basis that is speeding up production, enhancing economy of plant operation, and insuring uniformity in standards.

Until the war, National Iron Works San Diego, California, specialized in steel fabrication for large industrial and commercial structures and similar projects. Closest it had come to a strictly marine product was its famed Ingle ranges, used widely by fishing craft, and by the Navy.

But during World War II, National was assigned to produce numerous steel barges, and the company developed a "know-how" that in recent months has been adapted to large-scale output of clippers for San Diego's far-ranging tuna fleet.

Three 52-foot vessels already have been produced, and have made several long-distance voyages in fair weather and foul, surviving without serious damage some of the worst weather in the "chubasco" (hurricane) zone off the Mexican and Central American coasts.

A 70-foot ship has been launched and will be commissioned in March. The keel has been laid for a 105-foot clipper, and another one will be started soon. All this is being performed in National's spacious new yard, on San Diego's waterfront, at the same time all its traditional steel fabrication for buildings is proceeding at an accelerated peacetime tempo.

National cut its eye-teeth in the boatbuilding business with construction of the Juana, setting the pattern for the 52-foot class of tuna clippers, all of which are capable of 9-9½ knots speed and have a cruising range of 6000 statute miles. Fish-carrying capacity of the 52-footers is 34 tons.

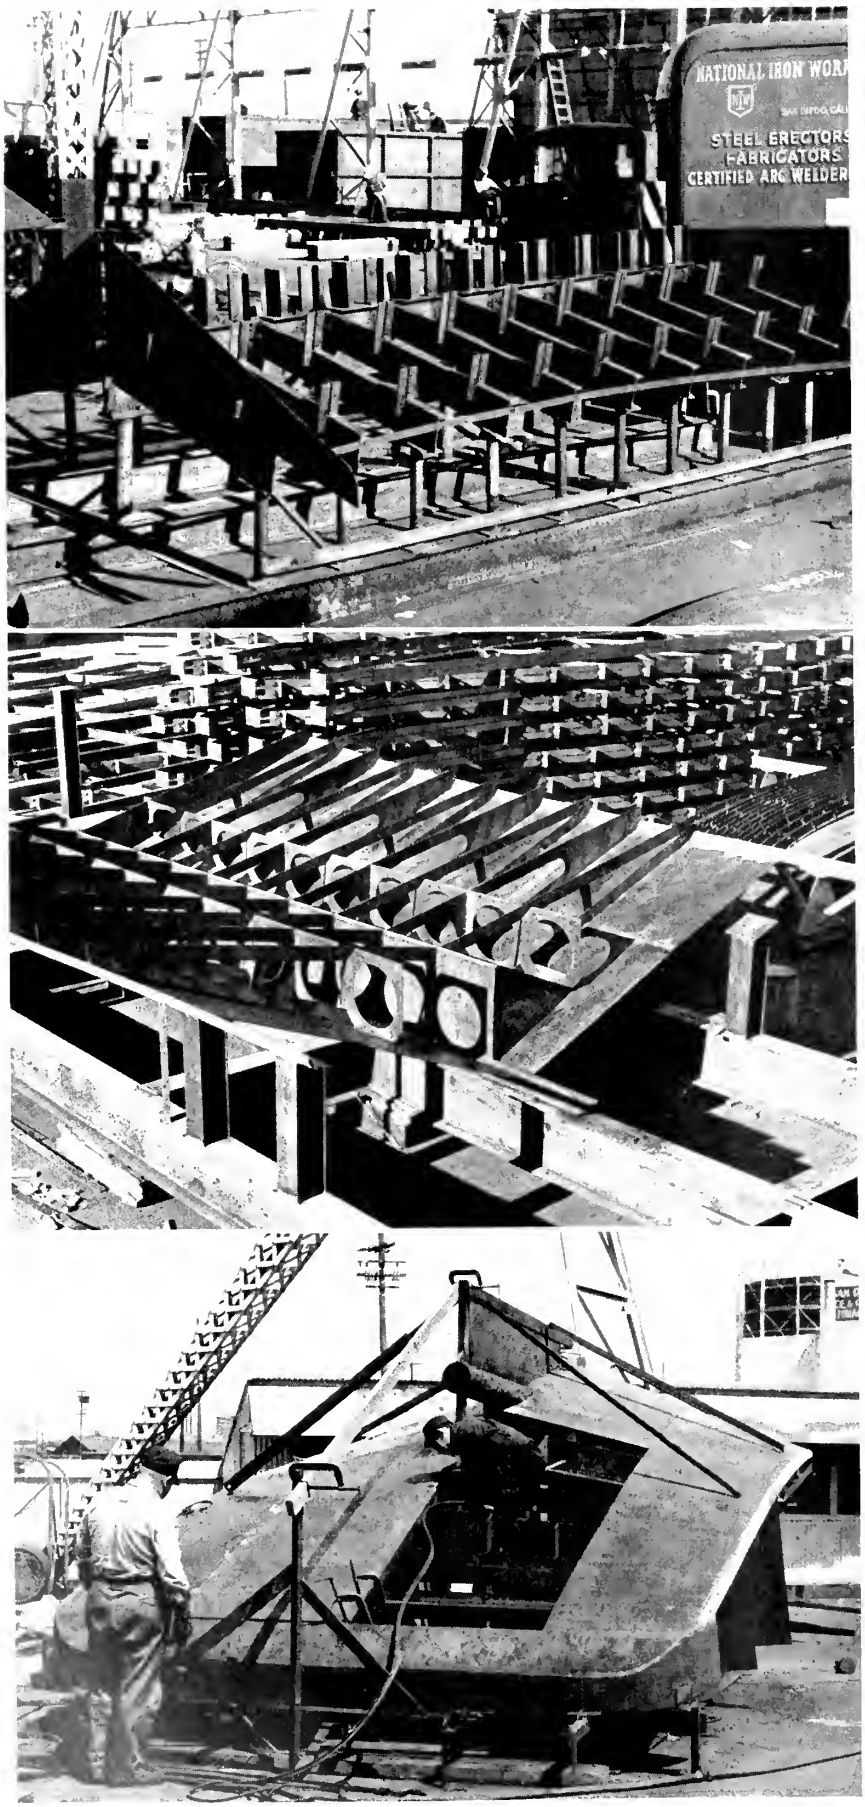
In mechanical equipment, the Juana differs somewhat from the Golden Bear and Lady, the other 52-footers. All are diesel-driven and have diesel auxiliary engines, but in the Juana the engines drive the generator, refrigeration compressor and pumps by means of belting to a line shaft. In the Golden Bear and Lady, the auxiliary engine drives a generator; the compressor and pumps are driven by means of individual electric motors.

Main engine of the Juana is a six-cylinder Model 65 Graymarine diesel with 3:1 reduction gears that can develop 165 hp at its maximum speed of 2000 rpm. The Golden Bear and Lady have Model D6-M six-cylinder Lorimer diesel engines rated 100 hp at 600 rpm.

Auxiliary engine of the Juana is a two-cylinder Graymarine diesel, equipped with a 12-volt electric starter unit with positive engagement of pinion through solenoid relay, and with a 12-volt, 250-watt generator with voltage control. Generator is belt driven. In the other two 52-footers, the auxiliary engine driving the 15-kw generator is a Model A2-S, 25-hp, 600-rpm Lorimer diesel of the four-stroke cycle, solid injection type.

Other engine room equipment on the Golden Bear and Lady includes a 7½-hp, 115-volt d.c. drip-proof, compound wound, marine type, 1750-rpm horizontal electric motor equipped with vee-belt pulley for driving ice machine; a 3-hp, 115-volt d. c. 1150-rpm horizontal electric motor for driving anchor windlass; a Campbell Machine Co. vertical impeller bait-water type pump with 5-hp ball-bearing vertical electric motor; and a Campbell horizontal and centrifugal type pump with 1½-hp ball-bearing electric motor. In addition, there is a Viking positive displacement gear pump, with built-in relief, back gear driven by a 1-hp ball-bearing electric motor for fuel transfer. Magnetic type starters, with Allen Bradley push-button control, are provided.

These vessels are equipped for ice refrigeration, and the system also provides for cooling brine in the bait well for chilling of fish. The 2-cylinder, 3½" x 3½" compressor is a Baker Ice Machine Co. product. The condenser is of the shell and tube type, 18 inches in diameter and 5



feet long. The receiver is 12 inches in diameter and 5 feet long. Approximately 1000 linear feet of 1¼-inch black steel ammonia pipe coils are provided in the fish holds, 300 linear feet in the bait tank, and 30 linear feet in the galley refrigerator box.

Insulation consists of 3 inches of granulated cork board in two layers on the underside of the deck, the sides, the end bulkheads, and the bottom, and on four sides and top of the bait tank on deck. All interior surfaces in the fish hold are finished with ½-inch waterproof plywood over the corkboard.

The shell and deck plating is of 3/16-inch steel. All frames are 3/16-inch steel bars and plates, except that ¼-inch plate is used for engine girders, engine room floors and center girder. A forepeak fuel oil tank, built integral with the ship's sides and bottom, has a 410-gallon capacity. The fresh-water tank, installed above the oil tank with a 3-inch cofferdam between them, has a capacity of 655 gallons. A lube oil tank of 85 gallons capacity is in the forward end of the engine room.

Under the fish hold is a fuel oil tank, with a capacity of 2310 gallons. Two more fuel oil tanks, one each side of a three-foot access passage to the rudder quadrant, can carry 675 gallons each.

Around the main deck is a 3/16-inch rail, with a 1-¾-inch hardwood rail cap.

Although the hulls are of steel, deck houses in all three 52-footers are of wood frame construction. Sides have ½-inch plywood exterior sheeting and ⅜-inch plywood interior sheeting. Deck overhead has ¾ inch of plywood sheathing. The deck house is securely fastened to a 3/16-inch steel coaming plate welded to the main deck.

Galley has a No. 114-S Ingle marine oil-burning range, equipped with Valjean carburetor.

The Juana has a Doran propeller, while the other two have Coolidge propellers. They are of manganese bronze, with 38-inch diameter and 22-inch pitch. The propeller shafts

Top: A special jig used to position correctly all the component members of a bottom subassembly of a 52-foot boat.

Center: This subassembly, a section of a ship's bottom, has been placed in a jig ready for joining to connecting subassemblies. It was first fabricated in an upside down position in another jig.

Bottom: Bottom plating being fitted to stern subassembly of 52-foot tuna boat.

are 2-11/16" cold rolled steel, with two intermediate Dodge Timken roller bearing pillow blocks.

The 70-foot tuna boat Pico, recently launched, has a beam of 19 feet and a molded depth of 9 feet, 9 inches. It has a raised fore deck and square stern. Fish holds include three brine wells on each side with a 3-foot shaft alley between. Forward wells are piped for fuel oil, and the middle wells for bait water. Fish carrying capacity is 74 tons, including the six wells in the hold and one well in the bait tank. Bunks are provided for eight men in the deck house, which also contains a storeroom, toilet and galley. Unlike the 52-footers, the Pico has a steel main deck house, but its pilot house is of wood.

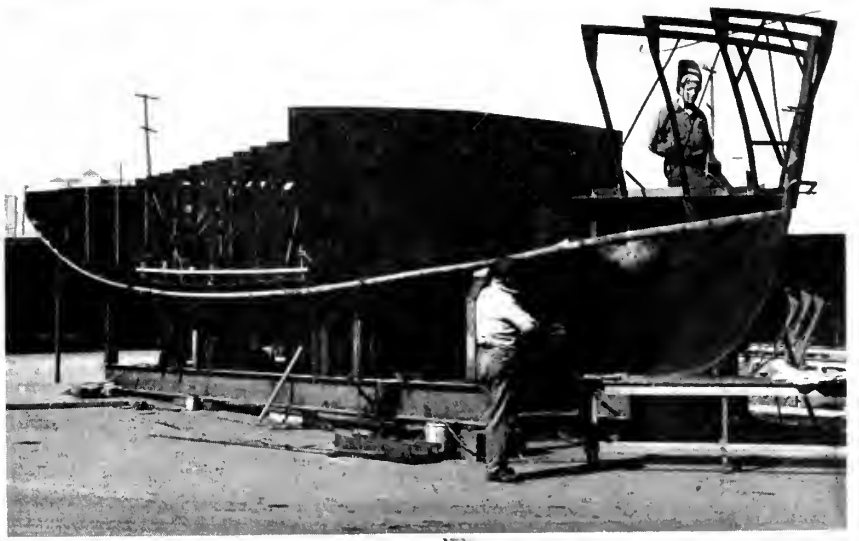
Regular fuel tanks have a capacity of 6200 gallons, and in addition, the forward fish wells can carry 6800 gallons of fuel oil, providing a combined capacity of 13,000 gallons suitable for a cruising range of about 12,000 miles. Lube oil tanks have a capacity of 400 gallons and fresh water tanks 700 gallons. Stern tanks can carry additional fresh water when used as trimming tanks.

Main engine is an 8-cylinder FA8-R Lorimer diesel, rated 200 brake hp at 600 rpm. Auxiliary engines are two Model D4 25-hp Lorimer diesel electric sets, with 15-kw Bardco generators.

Two Baker Ice Machine Co. 4-cylinder 3½" x 3½" are provided in the ammonia type refrigerating system. Galley has an Ingle oil-burning range.

The two 105-foot vessels will be the raised deck type, with slightly raked stem and modified tuna vessel type stern. They will be subdivided with five transverse oil and watertight bulkheads and transom bulkhead extending to main deck. Beam is 25 feet, and molded depth 12 feet. Brine well capacity under deck will be about 145 tons, and brine tank capacity about 27 tons. These craft will have a fish capacity of about 172½ tons.

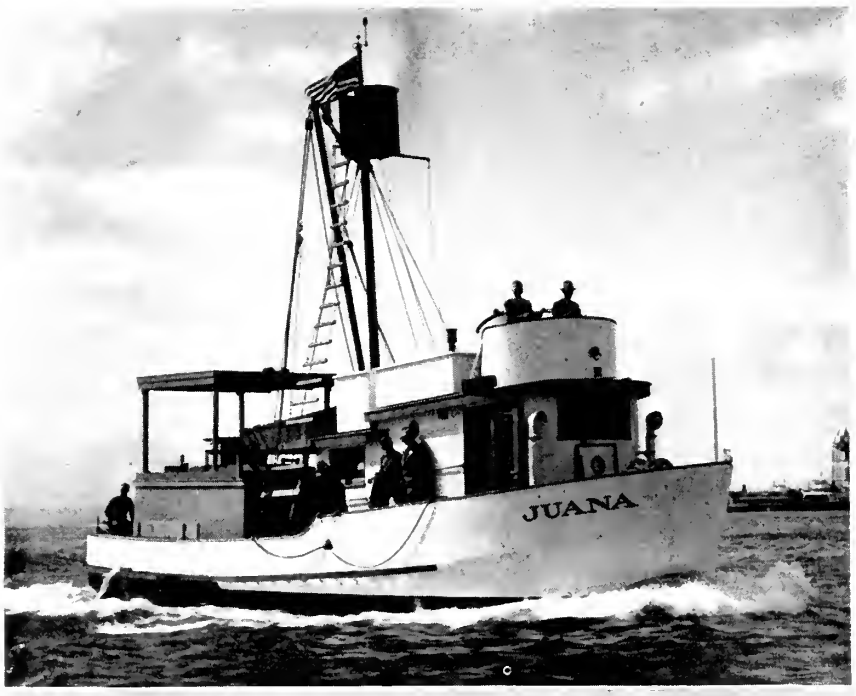
The pilot house will be of plywood. Three small boats, an 18-foot

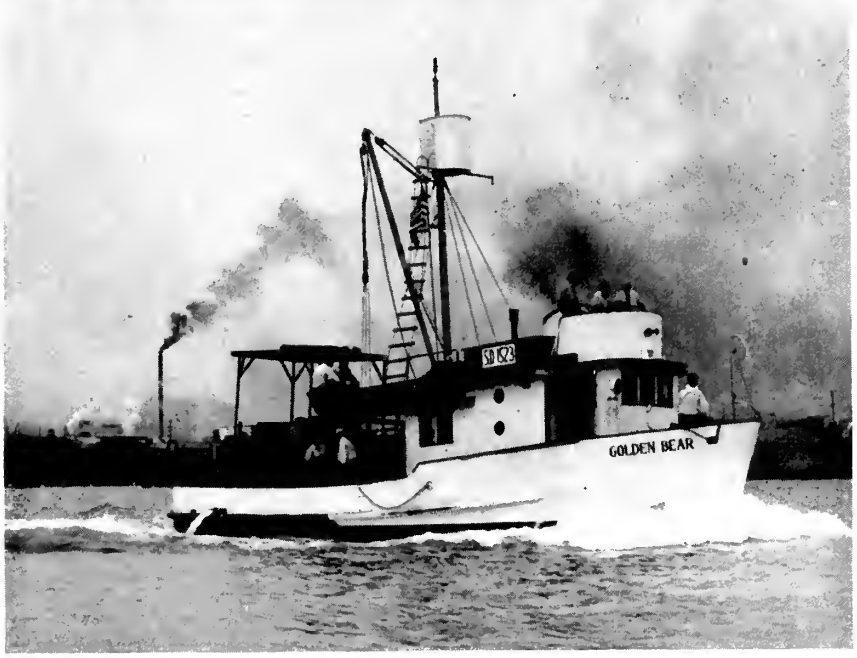


Top: A view along a portion of the waterfront in N. I. W.'s spacious yard. Shown are three of the N. I. W. built tuna vessels—the 70-foot Pico and the 52-footers Juana and Lady.

Center: Hull assembly work for a 52-foot boat in progress in a special cradle type jig.

Bottom: The Pico on stocks in the National Iron Works yard during final stages of construction prior to launching.





Upper: The Juana making 9.5 knots in her speed trials. Note the plywood construction of superstructure.
Lower: The Golden Bear on her trial run on San Diego Bay.

wood power speedboat, an 18-foot and a 13-foot skiff, will be stowed on the raised deck. Refrigeration for eight brine wells and two bait tanks will be the brine quick freezing system. Propelling engine will be a direct-reversible Model 6HM, 13″ x 16″, 550-hp, 300-rpm, 6-cylinder Atlas Imperial marine diesel engine, connected to a special William Lambie designed Doran propeller.

Auxiliary machinery will consist of two 75-kw a. c. Atlas Imperial diesel generating sets located on each side of the main propelling engine.

O. Tellefsen designed the hulls of the 52-footers and the 70-foot craft, while G. Bruce Newby of Long Beach designed the 105-foot clippers. National Iron Works contemplates a special streamlined superstructure on the larger boats, in accordance with sketches by Joslyn and Ryan, naval architects and marine engineers of San Francisco, to improve eye-appeal.

Work Boat Fire Protection

By H. H. Dierksen
Manager Marine Division
Walter Kidde & Co.

Workboats, tugs, barges, picket boats, dredges, schooners, draggers and launches are going to be turned out in quantity. They are going to be new in design and construction for small craft received a lot of scientific attention during the late war. Marine diesels have become more efficient and as a result more people will be able to afford to operate and maintain small boats.

Everyone who has been associated with the sea knows that good seamanship countenances no unnecessary risks. It is common sense to protect your boat with the most modern fire extinguishing systems. Carbon dioxide provides protection against a variety of common hazards.

In applying carbon dioxide fire protection to small craft, the owner has a choice of either a built-in system or portable extinguishers. For many reasons, the built-in type gives the best protection: for one thing, it eliminates the human element in getting the extinguisher to the seat of the fire, and it pipes the gas to the fire source in spite of fumes or flames. Also it enables the boat owner to smother an engine-room or bilge fire without opening doors or hatches.

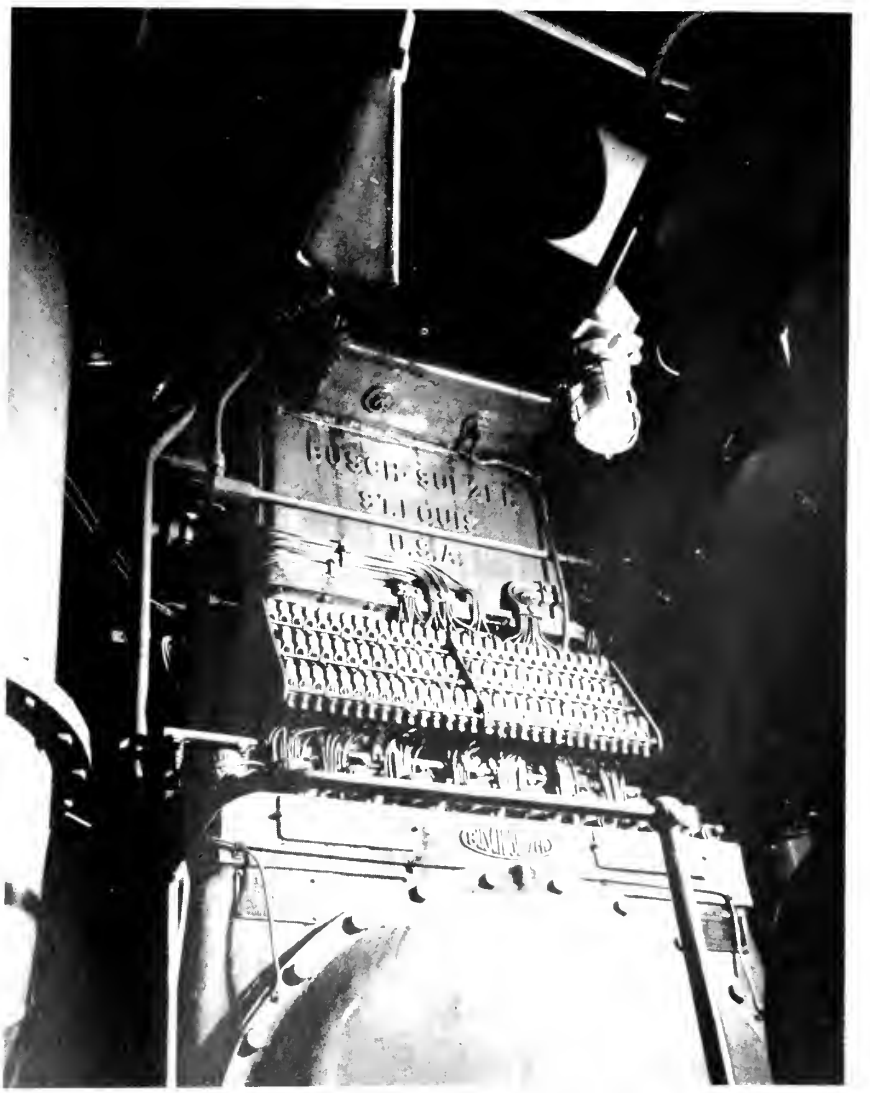
With built-in systems, discharge of the gas may be by manual control or fully automatic. Again it is best to eliminate as much of the human element as possible by the use of an automatic system, for many a boat fire occurs when no one is aboard to fight it, and many others are preceded by an explosive type of combustion that renders the crew incapable of quick, clear thinking and gives them a bad case of jitters.

In its most simple terms, a built-in extinguishing system consists of one or more steel cylinders containing compressed carbon dioxide, connected by pipes to discharge horns strategically located in the engine compartment and bilge. If and when gasoline fumes or drainage collect in proportions sufficient to catch fire, and the necessary spark or back-fire occurs, the valve is opened. Immediately the cylinder discharges a heavy, cold gas-and-snow discharge through

the horns to every nook and cranny of the engine and bilge spaces. Because this gas is inert, it so dilutes the oxygen that the fire is smothered —all in a matter of three to ten seconds.

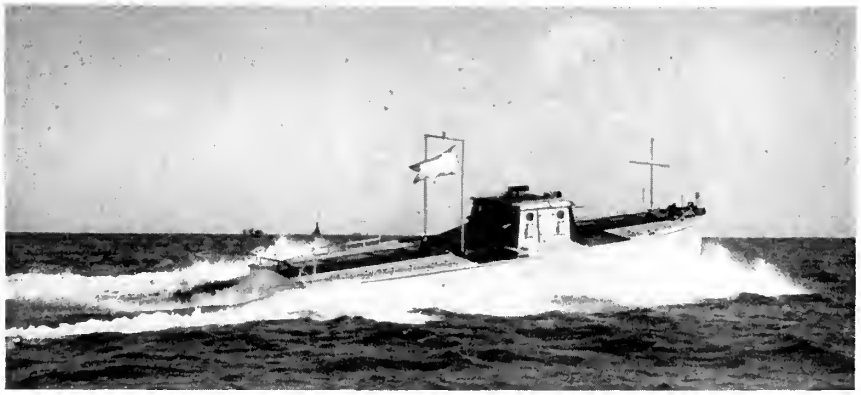
In case you have an engineering turn of mind, here is what happens—expressed a bit mathematically. There is normally 21 per cent of oxygen in the air, and gasoline needs only a 17 per cent oxygen content to burn fiercely. When the carbon dioxide gas system is discharged, it cuts the oxygen content to 14 per cent or less, and your fire is automatically out. This is true of bilge fires, fuel tank compartment fires, blazing gasoline streaming from a broken feed line, or conflagrations that fill the whole engine space. And, many boat owners have found their automatic systems discharged and smoke smudges on bulk-heads when they came aboard, but find no trace of damage. Also, there are cases of explosions blowing the hatches off the engine compartment, yet the carbon dioxide system puts the subsequent fire out immediately.

As mentioned above, carbon dioxide systems can be either automatically or manually discharged, depending on the layout of the boat and the habits of its owner. In automatic systems, for example, a small heat detector is mounted over the engine, and is connected to the discharge valve for releasing gas. Several types of detectors or actuators are available, but the one most commonly used is the "rate-of-temperature-rise" type. This consists of a small metal air chamber, the air in which expands upon sudden temperature jumps, ac-

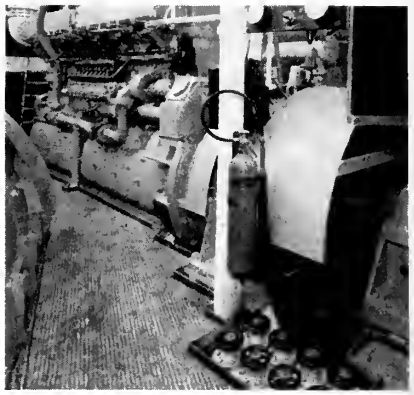


Upper: Such boat-fires as this one should be extinguished by using a portable carbon dioxide cylinder, like the one pictured. One thing that makes carbon dioxide so effective on boat fires is its three-dimensional characteristic. Fire itself is a three-dimensional phenomenon and burns around ribs, braces, pipes and all sorts of obstructions wherever oxygen is present—and it follows that an effective fire extinguisher must also move in three directions.

Lower: Machinery spaces are protected by built-in carbon dioxide systems, released from a point outside the engine room. The shielded nozzle in upper center is directed toward the potential fire hazard, and the blanketing gas penetrates the gratings in the machinery spaces to extinguish flames in hard-to-reach locations.



The ever-present danger of fires from gasoline fumes, which accumulate in the bilge of small boats like this one, can be dealt with by a portable carbon dioxide fire extinguisher. The non-toxic gas can penetrate the remotest parts of the boat, to blanket flames instantly. Galley fires also can be put out in a few seconds with such an extinguisher . . . and no harm is done to food or machinery.



Standing guard over a direct-current generator is a portable carbon dioxide fire extinguisher, ready for instant use. The non-toxic gas reduces the oxygen in the air to a point where fire can no longer burn. It is quick acting.

tuating the release valve through a length of copper tubing. Slow temperature changes, such as caused by sun or overheated engines, do not affect it, but outbreak of fire sets it off in two or three seconds. Even a candle flame held near the detector will actuate it. This system is entirely mechanical in its action, self-contained and independent of the boat's electrical system.

Smaller boats sometimes can have adequate protection by the use of portable fire extinguishing systems. At any rate, they are a mighty good "jury rig." Portables placed near fire hazards such as the engine room, and galley and the bilges can put out fires in a few seconds.

Carbon dioxide is harmless to any material, so harmless that food in the galley is perfectly edible after it has caught afire and the fire has been extinguished by carbon dioxide. When used on engine fires it does not hurt the metal or the working parts of the engine. Electrical fires can be quickly extinguished with complete safety. (Often it is forgotten that water is a conductor of electricity and electrical shocks result when some thoughtless person attempts to put out an electrical fire with a water or water solution type of fire extinguisher.)

One thing that makes carbon dioxide so effective on boat fires is its three-dimensional characteristic. Fire itself is a three-dimensional phenomenon, and burns around ribs, braces, pipes and all sorts of obstructions wherever oxygen is present—and it follows that an effective fire extinguisher must also move in three directions.

Coast Guard Announces New Line-Throwing Gun

Coast Guard Headquarters, Washington, D. C., has announced the existence of two new type guns, which were designed and developed by the Research and Development Division, Coast Guard Headquarters, Washington, D. C. Developed and designed specifically by Chief Gunner's Mate James E. Sieg of Baltimore, Maryland, the weapons carry his name.

One gun developed by Sieg is known as the Sieg Line-Throwing Gun. It was developed primarily for use by the U. S. Merchant Marine. It promises to surpass all previous models in both range and accuracy. The line-throwing gun is of .50 caliber, and uses a four-pound projectile with a 150-lb. test nylon line. It has a range of 400 yards, and a total weight of approximately 25 pounds. It uses two different types of projectiles: one of solid steel, and the other of steel, but with a mechanism in it for firing a CO_2 cartridge, which inflates a "do-nut" float upon impact against the water.

The other gun is known as the Sieg Automatic Rifle, which combines all the features of present automatic rifles, plus several new and revolutionary innovations. The gun is of 30.06 caliber, weighing 10⅝ pounds, and is 36 inches in length. It has a magazine capacity of 20 rounds. Full or semi-automatic, it has a rate of fire of 650 to 700 rounds per minute. It is composed of 103 parts. Folding sights permit the use of a "Bull Pup" stock. The double trigger is pivoted

for semi and full automatic fire. A combination safety and magazine release is located on the right side. It is equipped with a unique compensator that may be turned off for use with flash hider or grenade-launcher. This compensator does not interfere with the use of the above equipment or a bayonet. When tested by Army Ground Forces, Fort Benning, Ga., it produced excellent results. The effectiveness of the compensator is described as being so satisfactory that the weapon may be fired with one hand. Recoil is negligible, and the muzzle actually depresses unless the front is supported by hand.

The breech mechanism is entirely sealed to prevent dirt from entering working parts.

The first working model was built by Sieg aboard the USS Mohawk, C. G., in 1944. Two other models were built under the direction of the Research and Development Division of the Coast Guard Yard, Curtis Bay, Maryland. The present model was manufactured by the High Standard Manufacturing Company, New Haven, Connecticut, with plans designed by Sieg, on a contract from the Research and Development Division of Coast Guard Headquarters, Washington, D. C.

This latest model is being turned over to the U. S. Army for further test and study, and evaluation.

Sieg was born in Richmond, Virginia, in 1916. He was educated in Atlanta, Georgia, where he completed his schooling in 1936. In 1937 he enlisted in the U. S. Army as a private, and was immediately sent to Honolulu, where he served the remainder of his enlistment. In 1940 he was honorably discharged from the Army as a sergeant, and enlisted in the U. S. Coast Guard as an apprentice seaman. He received his first petty officer rating of gunner's mate 3/c in 1940, and subsequent advancements as follows: GM 2/c, 1941; GM 1/c, 1942; CGM, 1943. He has had duty aboard the cutter Tahoe, a sub-chaser on Greenland patrol duty, and the cutter Mohawk on North Atlantic patrol duty. He received his gunnery experience and training at the Coast Guard Gunner's Mate School, Curtis Bay, Maryland. Sieg is entitled to wear the European Theater Ribbon, American Theater Ribbon, American Defense Ribbon with Star, and the Good Conduct Medal.

The new Sieg line-throwing gun is demonstrated by its designer, Chief Gunner's mate James E. Sieg. Designed and developed by Sieg under the direction of the Research and Development Division of the U. S. Coast Guard primarily for use by the U. S. Merchant Marine, this gun promises to surpass all previous line-throwing guns in both range and accuracy. *(Official Coast Guard photo)*

National Marine Exposition

After more than three years as the largest U. S. Army induction center in the country, Grand Central Palace, New York City, has resumed its pre-war status as the home of expositions. For decades, "the Palace" provided the space and facilities for expositions of every character, and now, after extensive remodeling and restoration work, has reopened for business.

One of the first large post-war shows scheduled at New York's Grand Central Palace is the National Marine Exposition, which will be held the week of May 20-25. The exposition will be held under the sponsorship of the Propeller Club of the United States not only as a service to the marine industry but also as a feature in that organization's program to further develop public interest in the American Merchant Marine.

The marine exposition will be particularly timely. Public attention has been attracted to the American marine industry by its war record. In four years, American shipyards turned out a merchant fleet which today exceeds in tonnage the combined pre-war fleets of the world's leading maritime nations. Despite the loss of 743 merchant ships during the war through direct enemy action and marine hazards due to war conditions, the U. S. Merchant Marine consisted of 5,529 ocean-going vessels on February 1 of this year. Even more spectacular in the eyes of the general public was the war record of American ship operations which contributed so importantly to Allied victory.

Displays at the marine exposition will portray the part played by leading concerns in the industry during the war. Devices and equipment developed for war use but which will be adapted to peacetime service for improved navigation, safety at sea and more efficient ship operations will include radar, Loran and other electronic apparatus. Several large shipbuilding companies will exhibit models of ships constructed in recent years, while leading American steamship companies, again able to offer their facilities to the public for travel and shipment of cargo, will be on hand to show the traveler and shipper what they may expect of the new American Merchant Marine in the near future.

Other exhibitors will include manufacturers of marine machinery, engineering devices, specialties and equipment. Large oil companies will show displays, with experts in attendance to discuss problems relating to the lubrication of marine machinery. Also included will be displays of both wire and manila rope, the latest in marine paints for hull and topsides protection, and many other exhibits directly applicable to the marine field.

The present plan is to open the exposition to the general public only on certain days—the attendance for the balance of the week will be by invitation only, thus enabling the exhibitors to devote their undivided attention to shipping and shipbuilding executives, operating officials and others directly concerned with the various phases of maritime activity.

An elaborate program for the week of the exposition is now being formulated by the Propeller Club. Other leading associations in the marine field have been invited to participate, with each day of the week dedicated to a particular group or activity. Rooms will be made available in Grand Central Palace for meetings and other functions, with facilities for showing motion pictures provided for exhibitors and associations.

The week of May 20-25 was selected because this will be observed throughout the country as "Foreign Trade Week." May 22, the anniversary of the sailing in 1819 of the American ship Savannah on the first Atlantic crossing by a steam vessel, will as in previous years be observed throughout the country as "National Maritime Day." On the evening of that day the Propeller Club, Port of New York, will hold its annual Maritime Day dinner at the Waldorf-Astoria Hotel.

Three Floors—200 Exhibits

It is anticipated that the marine exposition will occupy three floors of Grand Central Palace. According to Roger E. Montgomery, general manager of the exposition, the number of exhibitors has now passed the one-hundred mark, and it is expected that that figure will be more than doubled by the time the exposition opens its doors.

"The American Merchant Marine," said Arthur M. Tode, honorary president of the Propeller Club of the United States, and Chairman of the Marine Exposition Advisory Committee, at a meeting of the marine press on February 8, "looks forward to an era of greatly accelerated activity in the post-war years." New and fast cargo ships will provide the shipper with more rapid and efficient service. All signs point to a greatly enlarged foreign trade both in volume and ports covered, and there appears to be no valid reason why the goal of twenty million deadweight tons of American shipping cannot be employed in our foreign and domestic waterborne commerce.

One most encouraging sign is the fact that American steamship companies have undertaken a program for the construction of 89 new passenger and combination passenger-cargo vessels which will provide unsurpassed passenger accommodations and high-speed cargo carrying service to all parts of the world. This program will add approximately 1,200,000 gross tons to the American merchant fleet and involves an estimated cost of between four and five hundred million dollars. Several of these vessels are now under construction and some will be delivered this year.

In sponsoring the National Marine Exposition, the Propeller Club has made it possible for the designers, builders and operators of these as well as other vessels to meet, under one roof, many of the leading manufacturers of the equipment and materials which will go into their construction and operation.

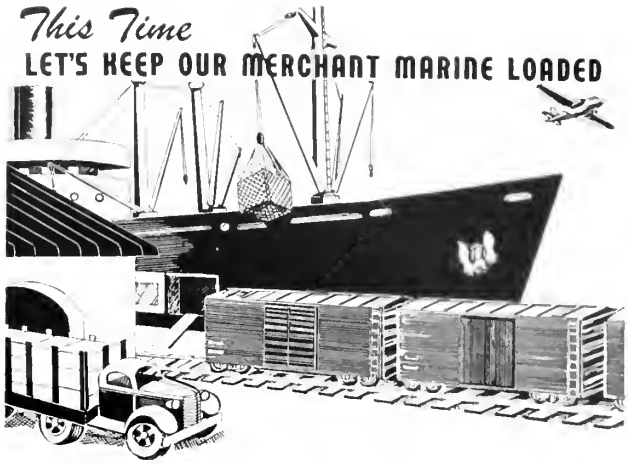
Pacific WORLD TRADE
Reg. U. S. Pat. Off.



By T. Douglas MacMullen

Dredge and Barge Built for War— Now Big World Trade Items

Post-war reconversion was no chore for the American Steel Dredge Company of Fort Wayne, Ind., and shipments are now being made of prefabricated barges, hulls and various types of dredges to foreign and domestic markets.

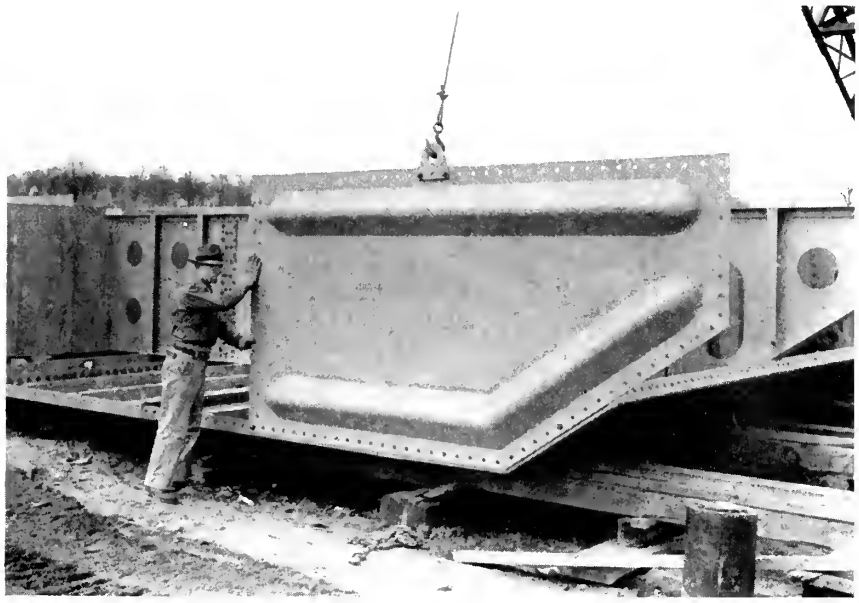
For 40 years the bolted, sectional steel craft of the American Steel Dredge Company have been working in rivers and harbors throughout the world, and early in the war when the Army asked the company to produce knocked-down barges there was little the company had to do except have the engineering department work out the particular designs the Army Transportation Corps wanted. The standard sections method of prefabrication and erection procedures was already well established. And the Army didn't want a conventional steel welded barge, but something that could be assembled in a hurry and by unskilled G. I.s if necessary. Later the Army Engineer Corps wanted a 12-inch hydraulic dredge similar to those the Fort Wayne concern had been producing for a world-wide market.

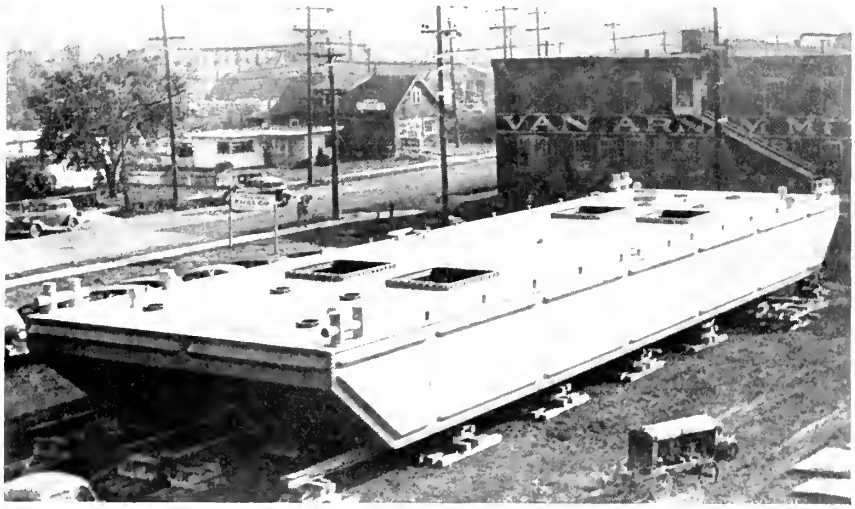
So, when the light turned green on V-J day, the company still had war contracts to complete but plans were no longer "post-war plans." They became "current business" overnight. Inquiries for dredges — hydraulic, dipper and clamshell, as well as barges—have been received from all over the world and American Steel Dredge has started shipments to those "inquiries" that have turned into orders.

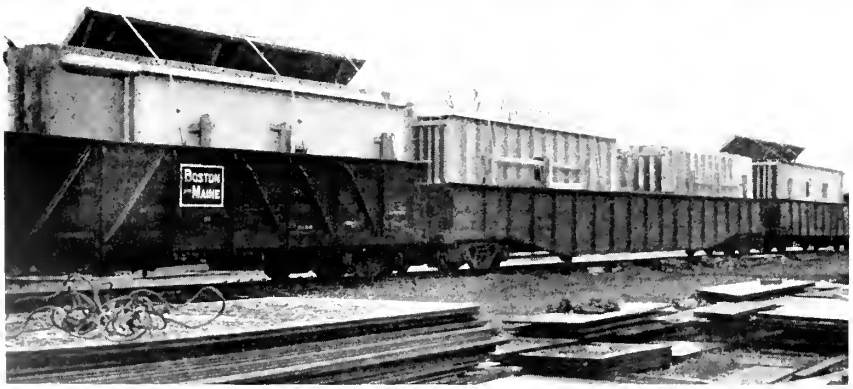
Walter W. Walb
President American Steel Dredge Co.

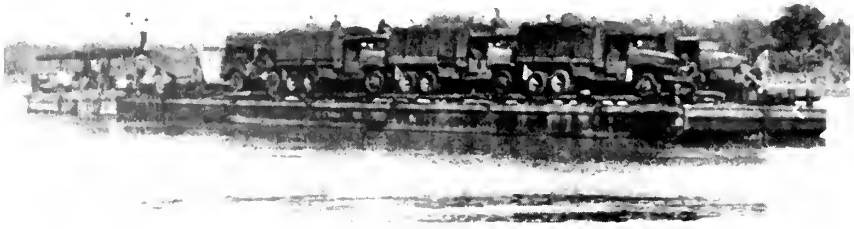
A barge designed for dry cargo only and very shallow waterways. Bow, stern and sides are raked. This type has a crew's house and rudder control. View of assembled barge, showing deck.

The company has also gone into production since the close of the war on an entirely new product. This is a rubber-mounted mobile crane unit with four-wheel drive that is being marketed under the name of "Wayne Crane." This is an all-purpose piece









of equipment and can be had with several attachments so that it can be used as a power shovel, trench hoe, dragline or clamshell as well as a utility crane.

The dredges and barges of the American Steel Dredge Company have several important points in the basic design that make them unique in the field of harbor and shallow waterways craft. All are made of prefabricated steel panels that can be shipped by rail or as hold cargo to the site of intended use where they are bolted together. The panels are made to such close tolerances that the last bolt fits as easily as the first.

After the dredge or barge has served its purpose in one spot it is possible to dismantle it and transport it to another location by rail, truck or ship and assemble it again at the new site. To make it easy for assembling and shipping the knock-down vessels, detailed assembly and packing manuals are provided with each craft. Nothing is left to the imagination in the manuals and they are so complete that assembly on many jobs has required not more than 500 man-hours, even by unskilled crews.

Ease of assembly is assured by the code-marking of each panel on the bottom, deck, sides, bow and stern as well as the longtitudinal and transverse bulkheads. All panels have been coded by the engineering department, and a marking plate with the code bead-welded on it is tack-welded to the panel. The position of these marks on each piece is important since it indicates the position of the panel when correctly installed.

To the amazement of Army and particularly Navy men of other countries who couldn't conceive that such a vessel wouldn't leak "just a little," these dredges and barges are watertight. This is taken care of by means of gaskets applied with plastic cement to the bolted joints.

For really speedy river and harbor work the barges can move under their own power through the installation of a "jumbo" outboard motor. Countless hours were saved by this means in moving supplies during the war.

The standard 12-inch hydraulic dredge of the American Steel Dredge

Reading from top to bottom: Installation of first side panel; close-up of completed liquid or dry cargo barge, showing bolted steel panel construction; all dredges and barges of the American Steel Dredge Co. are packaged like this for shipment to erection site—no deck space is required if transported by ship; a liquid or dry cargo barge with a deck-load of Army trucks going upriver in India.

A crane barge complete with crane.

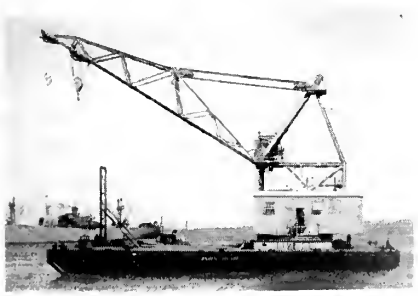
Company is on a hull 104′ x 29′ x 6′. It has a 36-foot digging ladder provided with an adequate margin of overload capacity and is fitted with interchangeable cutter heads to meet the changing character of material encountered on many dredging projects. A wooden deckhouse, enclosing all machinery, is also prefabricated to facilitate shipment.

The barges are produced in sizes from 40 to 120 feet in length. There is a crane barge in two sizes—on one of which is mounted a 30-ton crane and the other a 60-ton unit. Both earned many campaign ribbons during the war in battle-scarred harbors unloading equipment and doubling on salvage work—even to the extent of pulling up submarine nets.

Then there is the popular "348B" which is designed to transport either liquid or dry cargo. It was no uncommon sight during the war, particularly in India, to see these barges going upriver with a load of gasoline in the hold, or a deck full of airplanes or trucks.

Another barge is produced for handling dry cargo only. This is of very shallow draft and is raked on bow and stern and sides. Also included are a crew's house aft and steering control.

A 60-ton crane barge on the way to a harbor job.



What About Business In South America?

By P. P. Marion

Overseas Distributors, Inc.

Nearly everyone whom I have met—since my recent return from a business trip through the various South American countries—has evidenced a keen interest in almost anything and everything pertaining to that whole Continent, but the principal interest has been regarding the prospects for future business down there.

Now I do not presume to be an economist, or an expert business analyst, but it is quite obvious to me that the prospects for future business with all the South American countries are definitely excellent. They not only need almost every kind of product—from simple personal things to large industrial plants—but they also appear to prefer American-made goods, and to like us as a people.

However, it is my definite opinion that the extent to which anyone can take advantage of these opportunities will depend largely upon his understanding of Latin American conditions, and the manner in which such understanding is applied. By conditions, I mean the topography of the different countries and their respective economies, traits, customs and needs.

The average person does not seem to realize fully the vastness of the South American Continent or the tremendous amount of territory which is utterly uninhabitable. In the first place, the Continent is approximately twice the size of the United States—which you begin to realize when traveling by air for days upon days—and in the second place around 75% of it consists of either huge mountain ranges or vast forests or bleak, barren lands.

This rugged and difficult terrain forces the bulk of the people to concentrate in a relatively few communities, which are widely scattered, and makes it impractical to provide adequate land transportation between many of these communities. Thus, it is much more difficult and expensive to reach the various markets than in the United States, where we have excellent transportation and many communities close to each other.

Here a salesman can work several good cities during the same day—if necessary—and rarely has to make long jumps. Goods can also be shipped quickly and easily between almost any points. In nearly all the countries down there, salesmen must make long, time-consuming jumps from one buying area to another, or arrangements must be made for local representatives in each community. Delivery of goods is likewise difficult and slow, with the result that both selling and delivery costs are much higher, which in turn requires a greater allowance if maximum business is to be obtained.

Another point which many people do not seem to understand fully is the relatively small proportion of people who have any appreciable buying power in the majority of the South American countries. For example, Brazil has a total population of around 45,000,000 people, but is reputed to have a "buying population" of only three or four million. Most of the other countries have

P. P. Marion

Typical factory, Bogota, Colombia (Abbott Laboratories of U. S. A.).

about the same proportion, due to the fact that the majority of their populations consists of Indians and mixtures who have practically no income and live under the most primitive conditions.

Argentina and Chile, on the other hand, are composed principally of white people from good European stock, with the result that they have a better proportion of people with so-called buying power. This is particularly true in Argentina, where at least 90% of the 12,000,000 population are reported to be able to buy all the necessities of life, as well as many of the luxuries.

Thus Argentina, with a relatively small population, has a greater buying power than all of the other countries put together, and as soon as the current political situation has been adjusted this country should be an exceptionally fine market for American goods. Incidentally, prices were much less in Argentina, even though there has been some inflation there.

As a result of the above conditions, one cannot apply the usual U. S. formula when calculating the potential sales for a given product in a given area. Instead, it is advisable to determine first what the buying population is and then take into consideration their particular ways of living and their particular needs. For example, Ecuador and Venezuela have approximately the same population, but Venezuela has a much greater buying power, due largely to the influence of its oil resources. On the other hand, Buenos Aires is a much better market for heating units than Rio de Janeiro, as the former is fairly cold in winter, whereas Rio is always warm.

Similarly, some countries are much more agricultural than others, while certain areas are far more industrial. Likewise, some communities are still following the influence of the Spanish, or some other European country, whereas others are becoming quite modernistic, notably Brazil. Each country should be studied carefully, as they are all somewhat different in various ways. But that is what makes that Continent interesting, and offers excellent opportunities to those who really know the different conditions.

Still another important factor to take into consideration when planning South American sales is the matter of price, as this seems to take precedence over quality or value. For instance, the average person would prefer to pay $10.00 for something which would only last a year than pay $15.00 for a similar article which would last two years. This view is partly due to a lack of proper understanding of the difference between price and value—as we see it—and partly due to their relatively low incomes.

In this same connection, there is also the problem of overcoming the fact that prices seem much higher when converted into the local currency. For example, a radio might cost only $50.00 in U. S. money, but if the corresponding local unit of money is only .05c (U. S.) then the local price becomes 1,000 local units, which sounds like a lot more than 50. Furthermore, the relation of this cost to the local income is so much greater than in the States that it obviously results in considerable sales resistance.

Another price problem is the inherent trait for bargaining, which puts selling on an entirely different basis than Americans are accustomed to. Some sellers definitely provide for a sufficient additional margin so that they can satisfy this age-old trait, while others stick by their regular lists, come what may. Just what is the best method is open to considerable debate, but it is my opinion that the fixed price basis is the only safe course for Americans. The matter of so-called "greasing" is something else, however, which must be reckoned with, and provided for, as practically all business requires some special "hand-outs" here and there.

As for the extension of credit, this is indeed a problem, as South American buyers invariably want every possible advantage and more or less resent using their own capital. This attitude does not apply to all concerns by any means, but it is prevalent, and encouraged by some countries which will do almost anything to secure business. As a result, I found that the greatest criticism of American businessmen is their failure to extend sufficient credit. They seem to like us as a people, and seem to prefer American goods, but we definitely lose considerable business because of the credit angle.

Just what is the proper procedure is also open to considerable debate, especially as the majority of businessmen in the South do not seem to have the same sense of responsibility that most American businessmen have. Furthermore, we as a nation have never provided the same machinery for assisting our foreign traders as some other countries have done. The newly authorized facilities for stimulating foreign trade may enable American businessmen to extend more credit without undue risk, but if not, it would seem advisable to proceed cautiously wherever there is any doubt about the financial strength and moral responsibility of a given buyer.

There is also the matter of foreign competition, which is becoming increasingly active. This consists principally of British, Swedish and Swiss competition, which seems to have certain advantages in not only price and terms, but also delivery. This is a factor to be reckoned with, as the businessmen of these countries are very aggressive and much more realistic than many American busi-

nessmen. Everywhere you go you can see evidence of this competition in the form of machinery, motors, watches, luggage and whatnot, and with the war now ended there is bound to be still more evidence unless American businessmen wake up.

These are some of the principal problems and conditions which must be understood and met by those who want to share in the large amount of potential business which can be done with South America. And I do not believe that I am exaggerating when I say that the volume of that business can easily run into a tremendous sum during the next five to ten years.

Practically every city is in process of constructing new homes and factories and buildings of all kinds—hospitals, schools, office and Government buildings. There are also many projects for better streets and roads, improved sanitation, more playgrounds, better transportation and a higher standard of living. Furthermore, there is a definite trend towards making more and more articles locally, which will mean the purchase of all kinds of machinery and equipment. All these things will in turn create an ever increasing demand for the many related facilities and all the various things which go hand in hand with growth.

The best way to determine just what demand exists for a given product—and the best way to market it—is to make a personal tour, or entrust the problem with some responsible exporter who is in close touch with all the conditions down below. If a personal tour is to be made, it should provide for at least six months, as a quick trip to just the principal cities will only scratch the surface. One should also be able to speak the language fluently, as otherwise you will definitely miss many important things which are necessary to get a true and complete picture.

All the people you normally come in contact with are highly intelligent, very friendly and most hospitable. They have many customs, and some viewpoints, which are quite different from ours, but they also have many things in common. Furthermore, South America is not only a most interesting Continent which Americans should know more about, but it is unquestionably a field which American businessmen can cultivate to advantage and profit.

Oakland World Trade Department Has New Manager

Lyford M. Morris

Lyford M. Morris, president of the Junior Foreign Trade Association of San Francisco, has been appointed manager of the World Trade Department of the Oakland Chamber of Commerce. He takes the place of John A. Sowers, now with the Los Angeles Chamber.

Morris has a background of practical experience in world trade, having been with Matson and Moore-McCormack for many years, and during the war with the U. S. Treasury's Foreign Funds Control Division. He is a graduate of the University of California where he majored in foreign trade and shipping. The able Jack Sowers has an able successor.

Foreign Trade Week To Be Observed May 19-25

With "World Trade Puts Men to Work" as the theme, the eleventh annual National Foreign Trade Week will be observed throughout the nation, May 19-25.

Sponsored by the National Chamber of Commerce, the Week's observance serves as a means of focusing public interest on world trade as a vital factor in preserving free enterprise and expanding job opportunities.

Local chambers of commerce and other business and trade associations, farm and labor groups, factories and stores, schools and public interest organizations have been invited to participate. In his letter of invitation, Kenneth H. Campbell, manager of the Chamber's Foreign Commerce Department, outlined this background for this year's observance:

"Basic, far-reaching actions are now pending to make effective our policy toward and position in world trade. Specifically, Trade Agreements are to be negotiated with at least 14 nations; an International Conference on Trade and Employment has been announced for later this year and Congress is due to consider legislation affecting our commercial relations with the rest of the world."

As customary, the Chamber is preparing a manual and other materials which will be helpful in organizing local observance of National Foreign Trade Week through meetings, exhibits, school programs and contests, and other means of informing the public as to the contributions of world trade to the daily lives of everyone.

China-America Council Directory

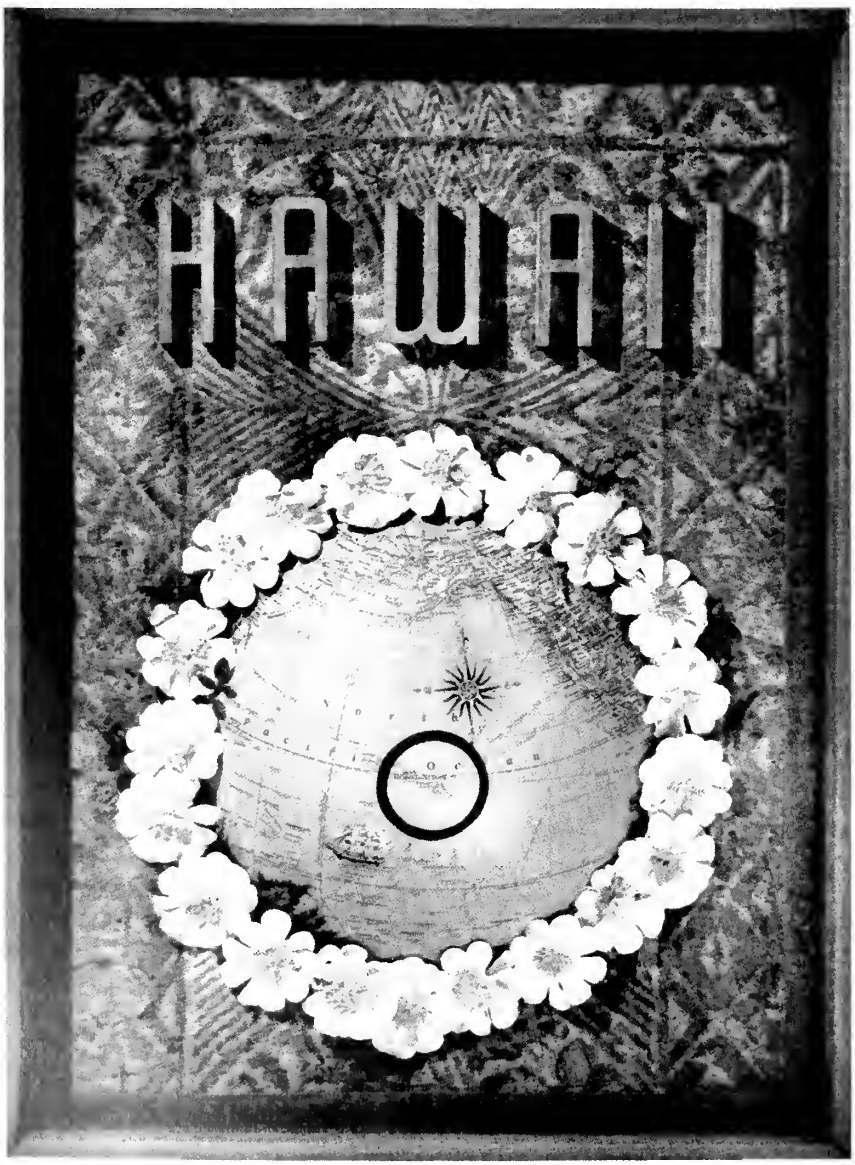
The China-America Council has started the preparation of a Directory, for distribution in China, listing and describing the goods and services handled by member companies. This Directory, the first promotional handbook of American products, services and companies to be distributed in China for many years, will be a cloth-bound book of approximately 400 pages. It will be distributed to thousands of industrial and trading organizations, government departments, financial institutions and technical schools and societies in China, as well as among the Chinese purchasing and planning organizations and commercial missions in this country. It is expected to be ready for distribution shortly after the opening of the Council's office in China, scheduled for early announcement.

Statehood For Hawaii

In Pacific Marine Review of October, 1944, we published an article urging that the Territory of Hawii be made a state, and announced that subsequent progress in that direction would be published as occasion permitted. The Congressional Delegate from Hawaii, Joseph R. Farrington, now sends us the report of the Committee which returned to Washington in January. —Ed.

Report of the Subcommittee of the Committee on Territories, the United States House of Representatives, on Statehood for Hawaii

The first congressional committee to hold hearings on the question of admitting Hawaii to statehood visited the Territory in October 1935. After extensive hearings the committee "found the Territory of Hawaii to be a modern unit of the American Commonwealth, with a political, social, and economic structure of the highest type." Nevertheless, the committee concluded that considerable further study was necessary before a favorable report might be made on a proposal to admit Hawaii as a State.



In October 1937, a joint congressional committee visited the Territory of Hawaii. The committee reported that while great progress had been made by the people of Hawaii, the question of statehood, because of disturbed international conditions, should again be deferred by the Congress until further study and consideration could be given. It was the committee's view also "that unmistakable evidence that a substantial majority desire statehood should precede affirmative action by Congress." A plebiscite to determine the wishes of the people was authorized by the Territorial legislature in 1939. Of those voting on the question at the general election of November 5, 1940, 67 percent favored statehood and 33 percent opposed it. A Gallup poll held on the mainland in 1941 revealed that opinion in the continental United States for and against statehood for Hawaii was in almost the same proportions as the Territorial view expressed in the plebiscite.

On December 20, 1945, just prior to this committee's departure, the Secretary of the Interior, whose Department has jurisdiction over the Territories, issued a statement endorsing statehood for Hawaii.

Findings

On the basis of the detailed and voluminous record made before it, the committee finds:

1. That the population of the Territory of Hawaii in 1945 was 502,122, of which 10,988 or 2.2 percent of the total population were Americans of Hawaiian ancestry; 61,422 or 12.2 percent were part-Hawaiians; 9,090 or 1.8 percent were Puerto Ricans; 172,583 or 34.4 percent were Caucasians; 30,005 or 6 percent were Chinese; 163,300 or 32.5 percent were Japanese; 7,042 or 1.4 percent were Koreans; 46,464 or 9.3 percent were Filipinos: all others 1,228 or 0.2 percent.

2. That the number of pure Hawaiians has declined from an estimat-

ed 300,000 persons in 1778 to 10,988 in 1945.

3. That the Caucasian population has increased steadily since 1878, when the percentage of the total population was only 5.09 percent.

4. That persons of Japanese ancestry in 1890 numbered 12,360 or 13.7 percent of the total population. By 1920 the percentage increased to 42.7 percent, but had declined to 37.9 percent in 1930 and continues declining, to date being only 32.5 percent, or 163,300 persons at present.

5. That since 1912 the proportion of interracial marriages has increased from 14.1 to 38.5 percent, the trend being accentuated by the recent war, during which over one-third of the children born had two or more racial strains.

6. That well over 85 percent of the present population was born in Hawaii or on the mainland.

7. That the war record of Hawaii is in every respect commendable. Hawaii had a full scale organization for civilian defense and volunteer defense units sponsored by the Army, and participated in Red Cross, USO, blood bank, and similar activities, making liberal contributions to the war chest, and oversubscribing its quota for war bonds. The Territory established a number of emergency agencies, such as a Bureau of Registration and Identification, Office of Food Control and Food Production, and a commercial rent control program.

8. That Hawaii did its part in contributing men to the armed forces. Selective Service did not apply to Hawaii during the first two years of the war, because of the Territory's crucial position and shortage of manpower. Since the application of the draft, Hawaii has met its full quota. Hawaii had two National Guard regiments which were called into the Federal service on October 15, 1940. In all, 33,000 of the citizens of Hawaii served in the armed forces. Americans of Japanese ancestry were rejected from March 1942 until February 1943 but made up for this as soon as they were accepted. Although Americans of Japanese ancestry constituted only 36 percent of the registrants under selective service, 52 percent of the total inductions from December 1940 to September 1945 came from this racial group, because of the large number of volunteers. Because of the Army policy of organizing and segregating units composed entirely of citizens of Japanese ancestry, it is possible to follow their activities and to see how they proved unwarranted the mistrust initially shown by the military commanders. Hawaii residents of Japanese ancestry constituted the entire original One Hundredth Infantry Battalion and by far the major part of the original Four Hundred and Forty-second Combat Team. The record of those units, made in major offensives in the European theater, includes 5 Presidental unit citations, 1 Meritorious Service plaque, 65 Distinguished Service Crosses, 290 Silver Stars, 782 Bronze Stars, 10 Criox de Guerre (French) 3 soldiers medals (Italian), 50 Army commendations, and 82 division commendations.

9. That, according to Robert L. Shivers, Federal Bureau of Investigation agent in charge at Honolulu, there was not one single act of sabotage or fifth-column activity committed in Hawaii before, during, or after the attack on Pearl Harbor. Hawaii's people of various racial ancestries can and do work together, and what goes on in the countries of their ancestors is of minor concern to them, compared to their interest in the United States. People of all racial ancestries cooperated in preparing for and prosecuting the war, and Hawaii, despite its polyracial composition, is essentially American in thought, purpose, and action.

10. That the people of the Territory of Hawaii are a law-abiding people. Its different racial groups live together with a minimum of friction and no racial clashes; life and property are as safe in Hawaii as in any section of the mainland.

11. Such evidence of bloc voting as exists indicates that the practice has not assumed, and is not likely to assume, serious proportions. Members of the Territorial legislature whose ancestry is Japanese constitute normally less than 20 percent of the total membership, although 32.5 percent of the total population of the islands is of Japanese descent.

12. That in 1944, 71,704 of 84,326 registrants, or 85.03 percent, voted in the general election. The percentage of registered voters of Hawaiian ancestry declined from 33.8 percent in 1932 to 24.7 percent in 1940; Caucasian voters declined from 38.2 percent in 1932 to 30.1 percent in 1940. The Japanese showed an increase from 17.6 to 31.1 percent. With few exceptions, the percentage of registrants voting in each general election ranged between 85 to 90 percent.

13. That of the Territory's 4,118,400 acres, 1,762,050 acres, or 42.78 percent, are in public ownership and 2,356,350 acres or 57.22 percent are privately owned. The largest single owner holds 8.87 percent of the total of privately owned lands and the 10 largest owners (including the largest owner) together hold 30.11 percent the 50 largest owners (including the 10 largest owners) hold 39.55 percent, and all other owners hold 17.67 percent of all privately owned lands.

14. That the largest owner is the B. P. Bishop estate, holding approximately 370,000 acres. This is a charitable trust, founded by a Hawaiian princess for the support of the Kamehameha Schools, which are devoted to the education of Hawaiians and part-Hawaiians, and the expenses of administering the trust are paid from trust funds.

15. That of the Territory's total 4,118,400 acres, 2,947,330 acres are devoted as follows: 1,045,085 acres are devoted to forest reserves; 164,205 acres to national parks; 84,040 acres to Army, Navy, or other public use (including territorial and county purposes but not including highways); 1,350,000 acres to pasturage; 220,000 acres to the growing of sugar cane; 63,000 acres to the growing of pineapples; and approximately 21,000 acres to the growing of other crops, including: 6,760 acres, truck farming; 4,000 acres, coffee; 2,090 acres, fruits; 2,067 acres, taro and field crops; 770 acres, macadamia nuts; and 5,438 acres for miscellaneous crops.

16. That in 1940 there were 2,094 farms of less than 5 acres, and 4,724 farms of less than 100 acres (including those less than 5 acres).

17. That in 1944 Hawaii produced 874,946 tons of sugar cane, the crop being valued at $65,498,532.

18. That in 1940—the latest year for which complete figures are available—Hawaii produced 22,341,429 cases of pineapple valued at $45,851,706.

19. That the coffee production of the islands in 1944 totaled 7,656,000 pounds, valued at $1,091,000.

20. That the Territory has consistently paid into the United States Treasury a considerably larger amount than the Federal Government, exclusive of military expenditures, has spent upon the Territory; its 1945 contribution amounting to $173,999,227.22.

21 That in 1944 and 1945 Hawaii exceeded several States in the total of its internal revenue collections.

22. That the finances of the Territory have been very well managed. At the end of the last biennium, on June 30, 1945, total budgetary resources of the Territory amounted to $68,339,384, with total obligations and reserves in the amount of $57,873,691, leaving an unappropriated surplus of $10,465,693. The bonded debt of the Territory as of December 31, 1945 was $16,520,000, with $7,151,344 in the sinking fund, leaving a net amount of $9,368,656.

23. That during the calendar year 1945 the following tax revenues were produced from the following sources:

Real property	$6,568,605.43
Personal property	3,697,620.65
Income, personal and corporation	3,529,447.21
Public utility	1,897,497.05
Liquid fuel	1,932,749.57
Compensation and dividend	8,819,507.92
Bank excise	50,000.00
Liquor	1,908,979.50
Tobacco	422,664.86
Gross income and consumption	10,460,310.25
Unemployment compensation	1,888,749.18
Business excise, poll, public welfare (prior years)	96,468.83
Administered by tax commissioner	41,272,600.45
Inheritance and estate	661,274.16
Insurance	451,472.58
Miscellaneous licenses	10,252.63
Administered by Territorial treasurer	1,122,999.37
Total	42,395,499.82

24. That there are 35 sugar companies operating in the Territory with a total capitalization of approximately $175,000,000 and with stock held by approximately 16,000 persons. There are five corporations, known as the Big Five, which act in the capacity of factors or agents for practically all of these plantations, and to some extent have substantial stockholdings in the plantation companies. The companies, with the number of plantations represented and the approximate percentage of sugar production for each group of plantations, are as follows:

	Number of plantations represented	Approximate percentage of total sugar production
American Factors, Ltd.	9	30.8
C. Brewer & Co., Ltd.	14	23.5
Alexander & Baldwin	4	20.8
Castle & Cooke, Ltd.	3	14.5
Theo. H. Davies, Ltd.	4	6.9
Total	34	96.5

The agency system is not used to such a predominant extent in the pineapple industry, although some of the "big five" are connected with that industry through stock ownership or other affiliation. The "big five" have other interests as well.

25. That the commerce of Hawaii with the continental United States exceeds that between the mainland and all but a few foreign countries. From 1935 to 1940, only five foreign countries—the United Kingdom, Canada, Japan, France and Germany—bought more from the mainland than did Hawaii. In 1940 the value of the Territory's imports from the mainland totaled $127,539,539, while the value of exports to the mainland was $102,145,130.

26. That bank deposits have increased from $4,662,131 in 1901 to $493,295,940 in 1945, much of the increase being due to the presence of Army and Navy personnel.

Joseph R. Farrington
Delegate to Congress from Hawaii

27. That Hawaii's gross assessed value of real property is over $500,000,000—higher than that of any State at the time of admission with the exception of Oklahoma.

28. That as of December 1945, 36,875 corporations, firms, or individuals were engaged in 54,412 different enterprises as employers or self-employers.

A. There were 12,918 persons or companies engaged in retailing, representing the following subdivisions:

Appliances, 66; auto dealers, 42; auto supplies, 69; bakeries, 61; barrooms and saloons, 380; books and stationery, 34; building materials, 10; chemicals, 17; cold drinks, 206; confectionery, 205; curios and novelties, 298; department stores, 12; drugs, 151; dry goods, 222; electric supplies, 21; equipment, 43; fish dealers and fish markets, 532; food products, 481; fountain and lunchrooms, 444; fruit and vegetable, 713; furniture, 91; general merchandise, 1,135; groceries, 641; hardware, 61; household products, 15; jewelers, 185; liquor stores, 173; lumber, 10; meat dealers and meat markets, 333; mill supplies, 11; music stores and composers, 23; newspapers, 25; nurseries, 88; office equipment and supplies, 27; optical, 17; poultry, 636; radio and radio supplies, 67; restaurants, 952; service stations, 387; shoe stores, 68; toilet articles and cosmetics, 55; wearing apparel, 172.

B. There were 2,999 companies or persons engaged in wholesaling, including the following types of wholesaling:

Appliances, 14; auto dealers, 14; auto parts, 36; bakeries, 55; beverages, 11; block printing, 19; boat-building, 10; bottle dealers, 21; building materials, 7; coconuts, 9; confectioneries, 23; curios and novelties, 137; drugs, 39; dry goods, 42; electrical appliances, 19; equipment, 16; feed, 9; fish dealers, 273; florists, 41; food products, 109; fruit and vegetable dealers, 280; furniture, 26; general merchandise, 264; groceries, 44; hardware, 12; household products, 5; jewelers, 70; junk dealers, 8; lauhala weaving, 166; leis, 19; lumber, 5; magazines, 7; meats, 56; music, 9; tobacco, 6; toilet articles and cosmetics, 11; toys, 10; wearing apparel, 32.

C. Eight thousand three hundred and fifty-eight companies or persons were engaged in producing raw products, including:

Dairies, 66; farming, 1,051; fishing, 350; flower growers, 214; hog raisers, 589; poultry producers, 811; sugar growers, 2,135; vegetables and fruits, 1,542.

D. One thousand four hundred and twenty-six persons or companies were engaged in manufacturing, including:

Alcoholic beverages, 12; bakery products, 86; block printing, 17; chemical and fertilizer, 30; clothing, 27; concrete, lime, and stone products, 11; confectionery, 20; curios, and novelties, 88; foods, 137; footwear, 21; furniture, 35; jewelry, 16; mattresses and springs, 12; nonalcoholic beverages, 38; soap, 7; wood products, 37.

29. That out of a total of 170,000 employees (not including part-time work by school children under the schools' temporary program estab-

lished to meet the manpower shortage) the sugar industry employs about 24,500 workers. Pineapple agricultural labor (not including the canneries) totals about 4,750; 11,300 are employed in manufacturing (excluding sugar); 10,700 in transportation, communication and other utility services; 23,000 in wholesale and retail trades; 13,500 in various service industries; 7,400 in diversified agriculture; 6,600 in construction and quarrying, and 3,000 in financial, insurance, and real estate establishments; 59,500 are in Government service and 4,075 in domestic service.

30. That since 1937 the Territorial legislature passed a number of labor laws, creating the Department of Labor and Industrial Relations, and dealing with such matters as apprenticeship, child labor, vocational training, vocational rehabilation, unemployment compensation, regulation of employment agencies; minimum wages and maximum hours, payment and collection of wages, workmen's compensation, and safety regulations.

31. That the Territory's Department of Labor is considered by the local representative of the Federal Labor Department as doing an able job, and the Territory's labor legislation as comparing very favorably with that of many progressive States and in some respects is in advance thereof. Hawaii's unemployment compensation law provides more liberal benefits than that of any State with the possible exception of New York.

32. That the average cash wage paid to sugar employees in 1945 is in excess of $5 per day for unskilled labor not including the value of perquisites, which include housing, fuel, water, lights, and medical and hospital services. The cash wage paid in the pineapple industry is comparable. Wages paid industrial workers have advanced in Hawaii more than on the mainland during the period 1940-45 and Hawaii now is on a par with the mainland.

33. That a standard 8-hour day is in effect throughout the Territory.

34. That Hawaii is the only Territory or State with the exception of Wisconsin to pass a little Wagner Act, extending collective bargaining to agricultural labor.

35. That unionization of labor has made strides during the past 10 years both in industry and agriculture; nearly all major industries, including the sugar and pineapple industries, are now organized or organization is pending therein.

36. That there are 46 organizations in the Territory affiliated with the American Federation of Labor, 68 with the CIO, 2 independent unions, and 5 Government employees' organizations.

37. That in 1940 there were 7 strikes involving 502 workers with 33,217 man-days lost; in 1941 there were 16 strikes involving 2,530 workers resulting in 34,241 man-days lost; in 1942 there were 2 strikes involving 49 men resulting in 67-man-days lost; in 1943 there were 4 strikes involving 202 workers resulting in 716 man-days lost; in 1944 there was 1 labor dispute involving 6 men with 60 man-days lost; and in 1945, up to November, there had been 9 strikes involving 1,047 men with 8,876 man-days lost.

38. That at the last Territorial election a majority of those elected to both houses were endorsed by organized labor.

39. That illiteracy in the islands among native-born citizens is almost nonexistent. Hawaii has well-equipped schools throughout the Territory, most villages and hamlets being provided with proper educational facilities.

40. The standards of instruction, according to United States Chamber of Commerce, are the same as on the mainland and higher than those in many States. The average number of pupils enrolled per teacher is 27.9 in Hawaii as compared with 31.4 in the United States urban schools and 26.1 in rural areas. The average pay per teacher in Hawaii is $2,014 annually as compared to $2,013 in urban centers and $1,018 in rural areas of the mainland.

41. That there is a public library on each of the principal islands. There are 82,435 registered card holders. Each island library owns a bookmobile serving rural schools and homes, and approximately $620,000 is spent annually on library facilities.

42. That the University of Hawaii compares favorably with many State universities. For the year 1944-45 there were enrolled 1,463 regular students and 1,145 graduate students. The university had financial support in the amount of $3,126,028 for the biennium 1943-45, of which territorial appropriations from general revenues provided 50.8 percent, university income 27.46 percent, and Federal grants 21.74 percent.

43. That the level of the Territory's spiritual life is in the best American tradition.

44. That in 1945 the board of health spent $1,623,385 or a per capita cost of $3.23 as compared with $1.66 in 1937.

45. In 1943, Hawaii's death rates from 18 causes were below the national median. The rate was higher for syphilis, tuberculosis, and accidents, including automobile accidents. The mortality rate of infants under 1 year had declined from 87 per thousand in 1930 to 30 per thousand in 1945; the number of mater-

THE SEXTANT

Chapter II

The Principle of the Sextant

In Chapter I (Description of the Sextant) we found that a small piece of glass gg′ (a movable reflector called the index mirror—see Fig. 4) is placed at I at the center of the arc AC and is attached to a movable radius IB (the index arm). By moving this index arm the plane of its surface (which is perpendicular to the arc AC) may be made to cut at any required point, e. g., B. Another piece of glass hh′ (the lower half only of which is silvered) is a **fixed** reflector, called the horizon glass, and is placed at H, perpendicular to the plane AC.

Now suppose a ray of light proceeding from the object Y in the direction YO hits the movable reflector I at the angle YIg, then by a well-known optical law, described later on, the ray will be reflected back in the direction IH, making an angle HIg′ with the movable reflector (index mirror) equal to the angle YIg.

Also at the fixed reflector H the ray IH will suffer another reflection in the direction HO, making with the reflecting surface hh′ the angle OHh′, equal to the angle IHh.

Now if we suppose an observer's eye be placed at O and another ray of light to proceed from the object Z along the same line ZHO, the two objects Y and Z will thus appear to come to the observer from the same point Z, the image of the object Y having been transmitted to him from the silvered part of H and the direct image of Z through the upper part of H, which is made transparent for this purpose.

The angular distance between Y and Z which is what is required is the angle O (60° in Fig. 4), and this angle by a second optical law is double the angle AIB (30°) measured along the arc AC.

Thus if the arc AC, which may be supposed to be the sixth part of a circle or to contain 60°, is so graduated that it reads twice that number of degrees, or 120°, then the reading off along the arc AC will be the value of the angle at O, and this is the method adopted in dividing the arc of the sextant.

Therefore, to observe the angle between any two objects such as Y and Z the observer at O looks directly at the left-hand object Z through the fixed reflector H. He then moves the index arm IB attached to the movable reflector I in the plane passing through O and the two objects Y and Z until he sees the ray proceeding from Y in the same direction as the object Z. Then the reading off on the arc AC measures the angle at O, the angular distance between the two objects Y and Z.

It should be pointed out that the observer's eye is seldom at O exactly, but at some other place in the line OH. When the objects such as the sun, moon or a star are at a considerable distance from the observer, however, this will make no appreciable difference.

Optical Laws

The two important optical laws used in the construction of the sextant are as follows:

(1) **The angle of incidence equals the angle of reflection.** That is to say, when a ray of light is reflected from a plane surface, the angle of incidence is equal to the angle of reflection. From this it may be proved that when a ray of light undergoes two reflections in the same plane with two plane mirrors the angle between its first and last direction is equal to twice the inclination of the reflecting surfaces.

In Fig. 5 a ray of light from a star strikes the plane polished surface MM, and the angle which this direction makes with the perpendicular (or normal) to the surface is called the **angle of incidence.** Now when this ray of light is turned back or reflected from the polished surface the angle which its ray makes is called the **angle of reflection,** and the law of optics is that these two rays always lie on either side of the perpendicular to the surface and equidistant from it—therefore the two angles are equal. Thus the **angle of incidence** equals the **angle of reflection.** This occurs in the sextant as described above when the ray hits the index mirror I and the horizon glass H, as shown in Fig. 4.

(2) **If a ray of light is reflected twice at the surface of two plane mirrors, the angle between the planes of the index mirror and the horizon glass is half the angle between the objects observed.** Or it may be put in this manner, that "the angle between the first and last directions of a ray is double the angle of the inclination of the reflecting surfaces to each other."

In Fig. 4, YIHO is the path of the ray of light from an observed object reflected from two mirrors I and H

(index mirror and horizon glass), which are perpendicular to the plane of the instrument.

YI meets HO at O. The angle O is therefore the angle between the first direction of the ray and the last direction; that is, the angle at the observer's eye.

The angle F between the normals (or perpendiculars at I and H) equals the angle between the planes of the index mirror and the horizon glass HBI. Now, by the law of optics just described above, this angle is half the angle between the objects observed. Therefore, in order to avoid doubling the angle HBI to get the correct angle, the sextant is graduated to double its actual reading, as shown in Fig. 4.

Admiralty Decisions

(Continued from page 244)

It may be that Judge Knox was satisfied in the **Lewis case** that the defendant there was **in fact** the employer, thus fully justifying his decision. It is only the theory set forth as the basis of decision, with which I disagree.

"Plaintiff suffers no prejudice nor loss of substantial rights. He may maintain his cause against the United States, his employer, by virtue of Public Law 17, 78th Congress, 50 U. S. C., Appendix, sec. 1291, as if he were proceeding under the Jones Act. He also has the right to maintain an action against defendant for damages for maritime tort (misfeasance). See **Brady** v. **Roosevelt S. S. Co.,** 317 U. S. 575, 1943 A.M.C. 1.

"It is finally contended that the question in issue is one of fact, which cannot be determined on this motion, but must be litigated as one of the issues triable in the state court. But the issue, upon which removability depends, appears from the record to rest upon undisputed facts and documents and hence may be resolved as a matter of law. At least the court can, on motion to remand, inquire far enough into the factual issue to ascertain whether the requisites of a cause of action under the Jones Act are present. **Aldredge** v. **Baltimore & O. R. C.** (8 Cir.), 20 F. (2d) 655."

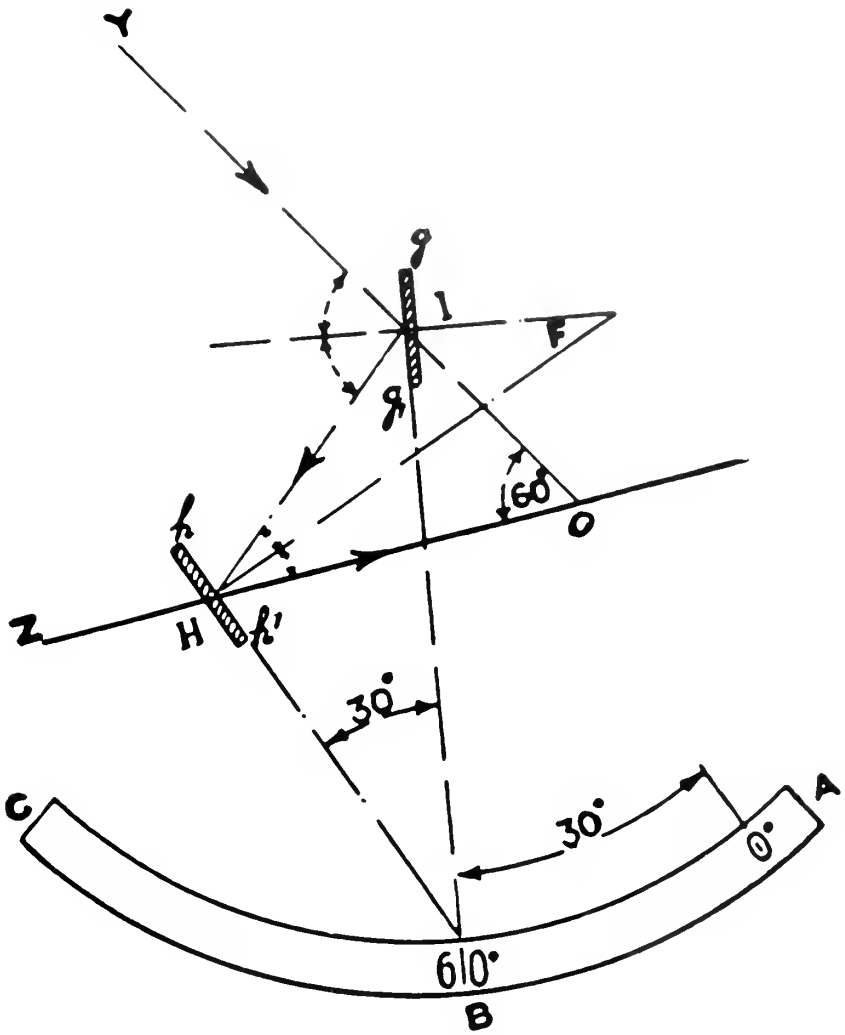

Fig. 4. The principle of the sextant.

Brush Terminology and Specifications

Brush Dimensions

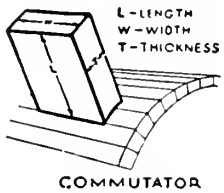

FIGURE 1

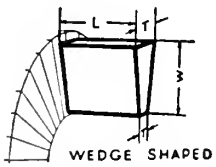

FIGURE 2

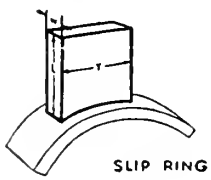

FIGURE 3

* * *

Brush Surfaces

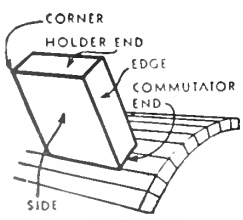

FIGURE 4

It is important that the terms used in specifying the style of brush desired should be clearly understood by both the purchaser and the manufacturer. The purpose of this article is to define and discuss some of the more important terms used in respect to brushes.

The Carbon Section of the National Electrical Manufacturers' Association has adopted numerous standard terms, definitions and practices. Much of the information presented herein is based on the recommendations of this body and some of the definitions are copied directly from NEMA standards.

Brush Dimensions

The overall dimensions indicating the size of rectangular or square brushes should always be given in the following order: length, width, thickness. For round brushes the order of dimensions should be: diameter, length. This order should be maintained regardless of the relative magnitude of these dimensions. Normally, length will be the greatest dimension of the brush and thickness the least, but on some brushes exactly the opposite relation may exist. As defined by the NEMA standards:

The length of a brush is the maximum overall dimension in the direction in which the brush feeds to the commutator or collector ring.

The width of a brush is the dimension at right angles to the length and to the direction of rotation.

The thickness of a brush is the dimension at right angles to the length in the direction of rotation.

These dimensions are indicated respectively by the letters L, W, and T in Figure 1 which represents a brush bearing on a cylindrical commutator. Brushes used on a radial commutator are wedge shaped, as illustrated in Figure 2, and thickness for both the thick and the thin edges should be specified. The thickness of slip ring brushes is frequently greater than the width, as shown in Figure 3, and may even exceed the length. However, as previously stated, the dimensions should always be given in the order length, width and thickness. A slip ring brush $1\frac{1}{2}''$ long x $1\frac{1}{4}''$ wide x $1\frac{3}{4}''$ thick should be specified as $1\frac{1}{2}''$ x $1\frac{1}{4}''$ x $1\frac{3}{4}''$, not as $1\frac{3}{4}''$ x $1\frac{1}{2}''$ x $1\frac{1}{4}''$. This is important where there is special machine work, such as a beveled or concaved face. If the latter order of dimensions were used the manufacturer would bevel or concave the $1\frac{1}{2}''$ x $1\frac{1}{4}''$ face of the brush whereas the machining should be on the $1\frac{1}{4}''$ x $1\frac{3}{4}''$ face in the proper position for rotation parallel to the $1\frac{3}{4}''$ dimensions.

Brush Surfaces

The following definitions have been adopted as NEMA standards:

The sides of the brush are the surfaces of which the limits are defined by the length and width of the brush.

The ends of the brush are known as the **holder end** and the **commutator end.** The end which is in contact with the commutator or ring is also known as the **brush face.**

When a brush has one or both ends beveled the front of the brush is its short side. (For parallel bevels, the front is the side making the widest angle with the face.)

The edges of the brush are the surfaces of which the limits are defined by the length and thickness of the brush. Edges are defined as right-hand or left-hand with the front (short side) of the brush toward the observer.

A corner of the brush is the point of intersection of any three surfaces.

Figure 4 illustrates the foregoing definitions.

Brush Shunts

It is often advantageous to equip brushes with connectors of flexible copper cable to provide a shunt or by-pass for the current between the brush and the rigid structure of the

machine. The flexible shunt provides a current path that is not affected by movement of the brush or clearance between the brush and the holder. One end of the shunt cable should be attached to the brush in a manner that provides both mechanical security and low electrical resistance and the other end provided with a suitable terminal for attachment to the brush holder or to the supporting arm on which the holders are mounted.

Five general types of shunt connections are in common use. These are the imbedded, riveted, bolted, saddle and plate types for which the following standard letter designations have been adopted by NEMA.

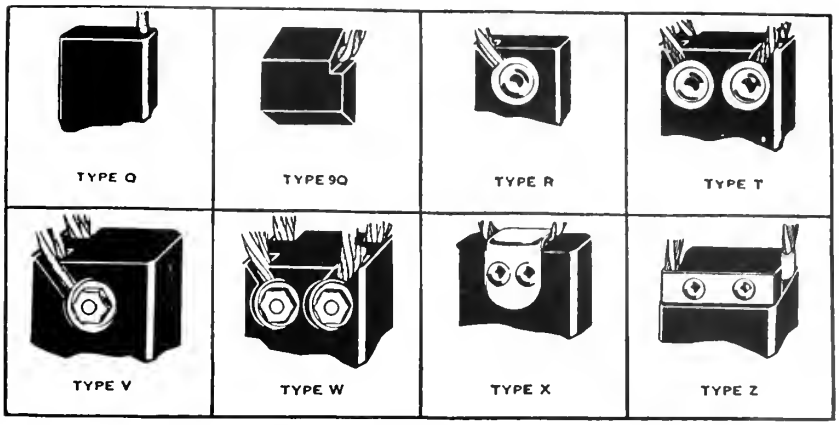

Figure 5. Shunt connections.

Embedded Types — Type M defines a connection in which the cable is molded into the brush at the time it is formed. In Type P the cable is wedged into a hole in the brush by means of a screw or driven pin. For Type Q a hole is drilled into the brush, slightly larger than the shunt cable and metallic material tamped in around the cable to secure it in place and provide electrical contact. This is the most extensively used of the various embedded types. Type S is one of the earliest types of shunt connections developed. The cable is inserted in a hole drilled in the top of the brush. Through an intersecting hole, drilled in the edge of the brush, counter-sunk and copper coated, solder is applied to secure the cable in place.

Riveted Types—In Type R connections one or more shunt cables are secured to the brush by means of a spun tubular rivet. When two rivets are used the connection is defined as Type T. Riveted connections are very stable and withstand considerable vibration or severe load conditions.

Bolted Types — When a bolt and nut are used to secure the cable the connection is known as Type V and two such connections on the same brush are defined as Type W.

Saddle Type—In this connection the shunt cable is fastened to a saddle which, in turn, is secured to the brush by means of one or two rivets. This connection is known as Type X.

Plate Type—Type Z connections are made by fastening the shunt cable to metal plates which are secured to the brush by rivets.

Typical construction of the various types of shunt connections described is shown in Figure 5. Specification of the type of shunt by letter includes all drilling, shouldering, slotting or other special machine work essential to making the connection but, with the exception of Type 9Q, does not include any other special machine work which may be desired. The Type designation 9Q covers a brush having both ends beveled, one or both edges shouldered and the type "Q" connection attached from the shouldered portion of the edge. When specifying this connection it is necessary to state the degree of bevel desired for the holder and commutator ends of the brush but the shoulders need not be mentioned. This style of brush is also known as the reaction or Baylis type.

Shunt Location

To simplify specification of the location from which the shunt cable leaves the brush the Carbon Section of NEMA has adopted a numerical code. Addition of the position code number as a suffix to the type symbol of the connection desired gives the brush manufacturer all the needed information in regard to shunt location. Figure 6 shows thirteen shunt locations for the common type of brush used on a cylindrical commutator and the code number by which each position is designated. For example, a riveted shunt with cable leaving the brush at the front side

SHUNT LOCATION

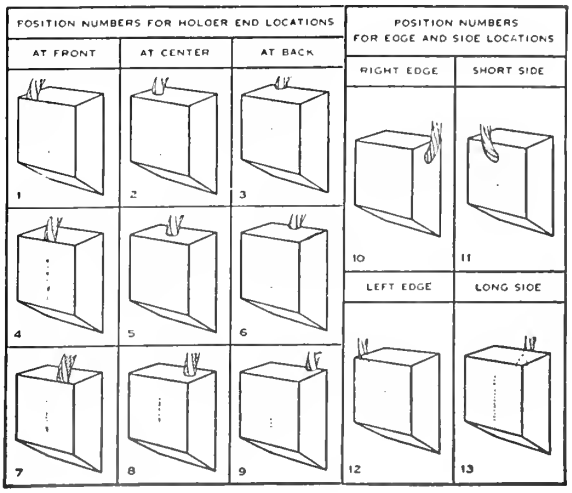

FIGURE 6

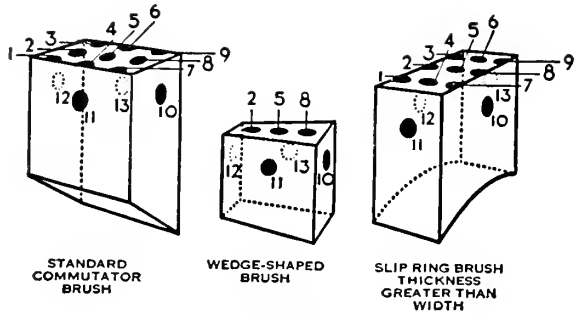

FIGURE 7

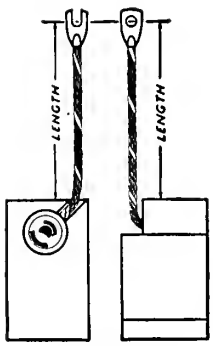

FIGURE 8
Shunt Length

and right hand edge, would be defined as a Type R-7 shunt.

In the left hand sketch of Figure 7 all of these positions are indicated on a single brush. The central sketch shows how the location code applies to a wedge shaped brush and the right hand sketch the application to a brush having greater thickness than width. In applying this code the brush should be held with the short side toward the observer. In the case of wedge shaped brushes, hold the thinner edge toward the observer's left, as illustrated.

Other Shunt Details

Length—Shunt length is defined as the distance from the holder end of the brush to the center of the hole or round portion of the slot in the terminal, as illustrated in Figure 8. Principal standard lengths for shunts on brushes ½" wide or over are 3½", 5½" and 7½". These lengths meet practically all requirements and, when shunt length is designated, a standard length should be specified. If length is not specified a 5½" shunt will usually be supplied.

Cable—The important cable sizes recognized as standard for brush shunts are shown in the table herewith.

It is not necessary to specify the size of cable when ordering brushes. Brush manufacturers base the selection of cable size on the cross sectional area of the brush, the carrying capacity of the grade supplied, and the rated carrying capacity of the cable. The rated carrying capacity is ample to insure freedom from overheating of the cable within the normal overload capacity of the brush.

Brush shunt cables are frequently insulated when the brushes are to be used on machines of compact design where there is chance of the cable being grounded or shorted by contact with the frame of the machine. Cotton sleeving, rubber, asbestos, lava beads and glass fabric sleeving are used for this purpose.

A great variety of shunt terminals are in use, some cut from heavy gauge metal, others made by folding sheet metal in a suitably formed die over the spread end of the cable and still others formed by pressing copper tubing onto the cable. There are flag type terminals, plug type both threaded and plain, button type and other special types. For most machines, other than those with cartridge type holders, folded terminals, either slotted or with hole, can be used. If the brush manufacturer's catalogue is not available, from which to select the particular style and size of terminal desired, it will usually be sufficient to specify width of slot or diameter of hole, making sure that it is large enough to pass freely over the fastening screw provided on the machine. The dimensions for terminal slots and holes most used are 5-, 7-, 9-, 11-, and 13-32". Figure 9 shows a few of the styles of terminals in common use. For unusual styles, where a standard type is not applicable, it is well to send a sample or a detailed sketch with the essential dimensions specified.

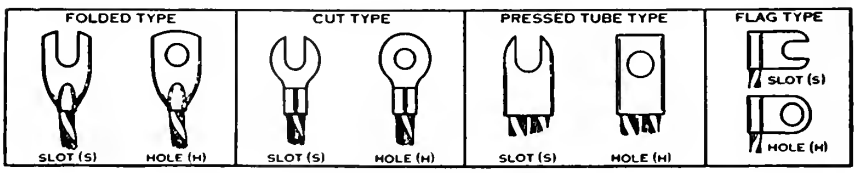

Figure 9. Shunt terminals.

BOOK REVIEWS

"Science of the Seven Seas"

By Henry Stommel: 200 pages, 107 illustrations, format 5 in. x 7½ in. Published by The Cornell Maritime Press. Price $3.00.

Students, seamen, pleasure voyagers, and all who love the sea and are curious about the wonder of the seas, winds and stars will find a wealth of fascinating, easy-to-read information in this hand book of the sea.

Henry Stommel, (Fellow of Pierson College, Yale University and now on temporary leave for special research work with the U. S. Navy at the Oceanographic Institute, Woods Hole, Mass.) describes and explains, without being too technical, the natural phenomena one observes at sea. Drawing on scientific discoveries in the fields of oceanography, geophysics, hydrodynamics and astronomy the author gives a simple readable description of waves, ocean currents, chemistry of sea water, submarine topography, icebergs, marine animals, plants, sea birds, cyclones waterspouts, clouds, winds, St. Elmo's Fire, sun dogs, submarine volcanoes, the tides, terrestrial magnetism, the sun, the moon and the stars.

Divided into three parts, "Science of the Seven Seas" includes:

1. The Sea, Waves, Ocean Bottom, Nature of Sea Water, Tides, Ice, Currents, Shore and Island.

Part II. The Sky, Atmospheric Optical Illusions, Upper Air, Fogs, Clouds, Lightning, Winds, Celestial Bodies.

Part III. Ocean Life, Plants, Fish, Sea Birds.

Merchant Marine Cook Book

Publication of the first comprehensive cook book ever compiled for use of Merchant Marine cooks, bakers and stewards was announced by the War Shipping Administration.

The profusely illustrated 337 page manual, Cooking and Baking On Ship Board, has been prepared under the guidance of culinary experts and thoroughly covers every aspect of efficient cooking, baking and meat cutting methods. Its 450 test recipes, each set forth in tabular form for ready reference, have complete data on preparation time, use of left-overs, and suggested variations. However, it is not for the housewife, as the quantities are measured out in portions for supplying groups as great as a hundred at a meal.

The manual is being distributed among all stewards, cooks and bakers on U. S. Merchant Marine vessels holding ratings not lower than Second Cook Baker, and to all U. S. Maritime Service Schools. Qualified persons may receive copies also at Room 422, 220 Bush Street, San Francisco; Room 2, 111 W. 7th Street, San Pedro; Room 1472 Dexter Horton Bldg., Seattle; and Room 606 Porter Bldg., Portland, Oregon.

On the Ways—

SHIPS IN THE MAKING

Six thousand tons of meat drydocked, valued at $3,600,000 aboard this collision-damaged British freighter, the Papanui.

Drydocked Ship's Meat Cargo Saved in Unique Job by Todd

A cargo of almost 6000 tons of frozen and chilled meat for the Navy aboard a damaged freighter that had to be dry-docked was saved from spoilage by a unique operation, performed at Todd Shipyards Corporation's Brooklyn division in the closing weeks of the war, which involved hooking up special water connections to supply the 25,000 gallons of water an hour necessary to keep the vessel's refrigeration plant in operation.

The vessel, the Papanui, operated by Norton, Lilly and Company, loaded with a cargo of meat valued at $3,600,000, in addition to 744 tons of general cargo, was proceeding through Gravesend Bay last July 14 on the start of a voyage to Pearl Harbor when she was in a collision with the James Caldwell. The Papanui's bow was completely crushed.

Because of the combined weight of the 10,000-gross ton ship and her cargo, it would have been necessary to remove the cargo, with considerable expense, spoilage and loss of time, if the vessel had entered a floating drydock.

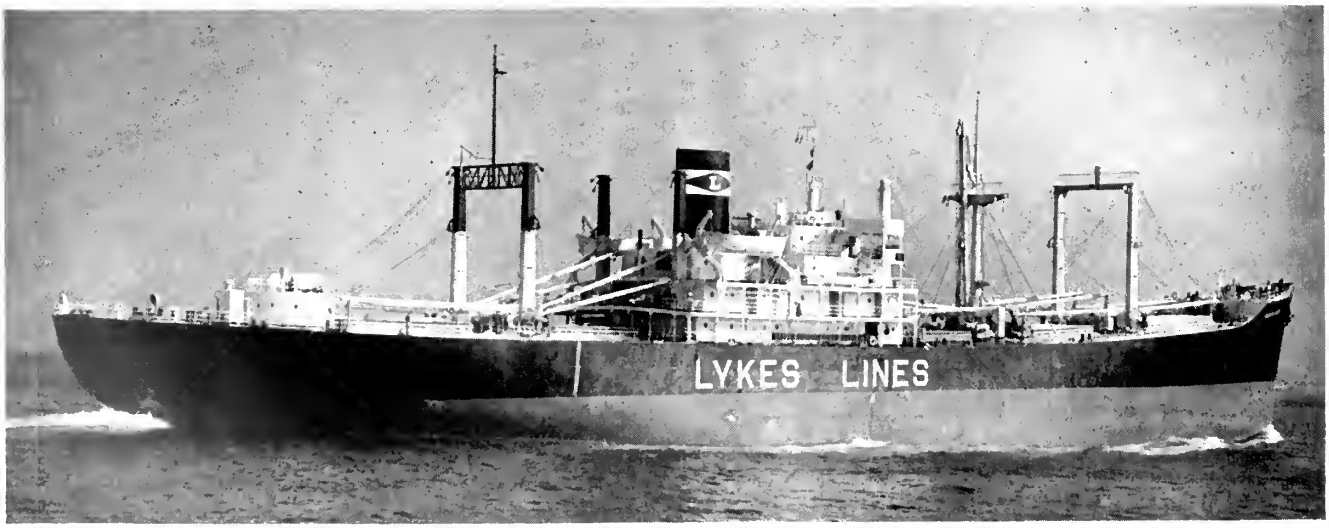
Alexander Kirkaldy, marine superintendent of Norton, Lilly and Company, decided that since the Papanui's cargo was urgently needed by the Navy, he would take the responsibility of doing something he said had never been done before—ordering a ship into drydock with a highly perishable cargo still in her holds.

Todd Shipyards Corporation took on the job, and the ship was placed in the concrete No. 1 graving dock in its Brooklyn plant. During the eight days the vessel was in the dock—while workers restored the ship's crushed bow and performed other extensive repairs—the pumping of 25,000 gallons of water an hour went on continuously. The result was that the much-needed cargo was kept aboard intact and the ship was able to depart immediately after the completion of the repairs, with days of precious time saved—as well as the meat.

Besides the restoration of the bow, which involved the removal of 32 shell plates, it was neeessary to install a new cast hawse pipe and to make extensive replacements of internal structural members. The total repairs required twenty-one days to complete.

Mormacdawn Launched

Mrs. Owen Brewster, wife of a United States Senator from 'way down east in Maine, recently sponsored a colorful launching 'way down



BOUND EAST, for Oriental peacetime trade, is the fast 12,800 ton cargo carrier Doctor Lykes, built for the Maritime Commission by U. S. Steel's Federal shipyard at Kearny, New Jersey. She has just passed all her test trials. They included a compass adjustment and anchor test. Then her engines were tuned to full speed ahead. Next was an exacting astern maneuvering operation. Taking that in her stride, she was given a series of steering manipulations. She mastered the sea with the assurance of a sea lion.

south in the still-thriving shipbuilding city of Pascagoula, Miss.

The occasion was the launching of the 18,000 ton all-welded passenger cargo liner Mormacdawn, the third of a fleet of seven vessels being built for the Moore-McCormack Lines by the Ingalls Shipbuilding Corporation.

Accompanying Mrs. Brewster on the launching stand was her husband, Senator Brewster. Others in the party included Captain and Mrs. Charles F. Brewster, of Washington, D. C.; Lieutenant and Mrs. Charles T. Mattmann, of Forest Hills, N. Y.; Mr. and Mrs. Albert V. Moore, of Forest Hills; Mr. and Mrs. G. E. Donovan, of Scarsdale, N. Y. Mrs. Charles F. Brewster, daughter-in-law of Senator and Mrs. Brewster, assisted in the formalities as matron of honor. Mr. Moore is president of Moore-McCormack Lines and Mr. Donovan is vice president.

It was the 77th ship launching at the Ingalls shipyard, and the first in a parade of launchings of peacetime liners scheduled for production at the yard during 1946.

SS Santa Cecilia Recently Launched

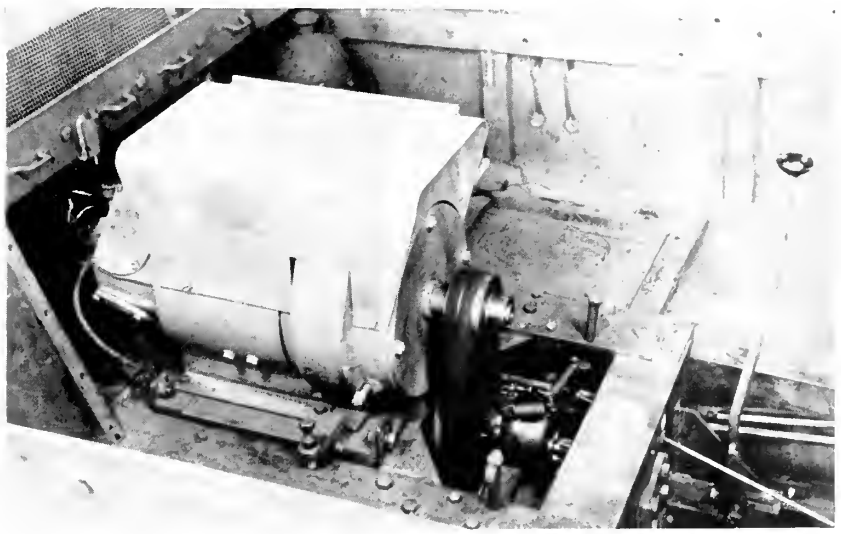
In the building program of nine new combination freight and passenger ships, which President R. Ranney Adams recently announced would be added to the fleet of 20 vessels to handle Grace Line's services in various trades, the S. S. Santa Cecilia, second in the unit now being built, was launched February 8, from the ways of the North Carolina Shipbuilding Company, at Wilmington, N. C.

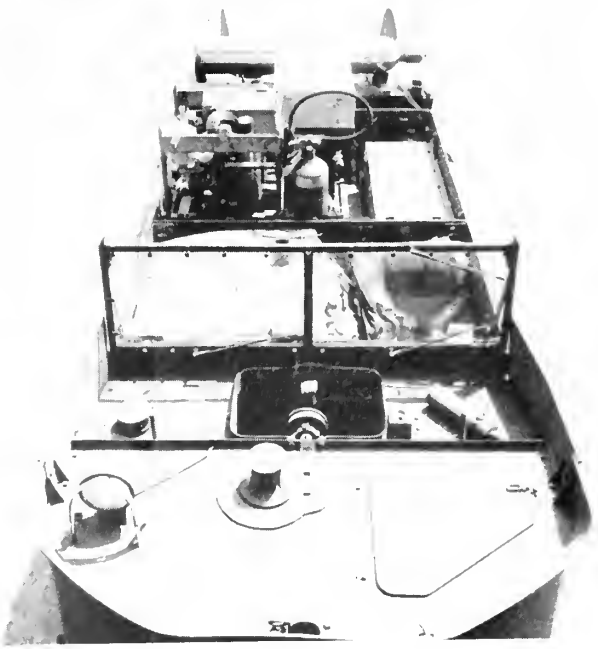
Converting "Weasels" to Amphibious Welding Units

The Navy felt that one of the prime needs during invasions was for a highly portable welding unit injured equipment repaired quickly that could go almost anywhere, get for action, and then move on to another job without loss of time. The U. S. Navy Carrier M-29-C, "Weasel," was selected by the Navy Bureau of Ships because of its maneuverability which allows it to go ashore at the same time as the units it was later to repair.

The Davey Compressor Co.'s. model 50-B heavy-duty truck power takeoffs were installed between the "Weasel" engines and differential driving assemblies, permitting the "Weasel" engines to drive 200-ampere welding generators. This eliminated the need for a special generator engine, leaving valuable space in the "Weasel" for working room, materials and personnel, and bringing it within the cargo-carrying capacity of the "Weasel" when operating in rough water.

The installation of the Davey power take-off was much the same as an installation of the take-off in a 1½ ton truck to drive an air compressor, welding generator, pump, transit mixer or other equipment. Only minor engineering changes were necessary to adapt standard Davey equipment to this special Navy use.





Above: **Close-up view of Davey model 50-B heavy duty truck power take - off installed between engine and driving assembly of U. S. Navy Carrier M-29-C, famous as the "Weasel," used to drive G. E. 200-ampere welding generator for fast repairs during invasion operations.**

At right: **The famous Navy "Weasel" equipped for fast beach head repair work.**

U. S. Seamen Have Highest Wage Rate

It has long been known that American steamship companies lead the world in the amount of wages paid to seamen. The most recent tabulations of basic wage rates for seamen in the fifteen leading maritime nations shows, according to the report of War Shipping Administration agents, the following scales:

	Basic Monthly Rate
United States	$145
Canada	81
New Zealand	68
Netherlands	63
Norway	58
Australia	57
Great Britain	56
Poland	56
France	54
Sweden	53
Belgium	49
Greece	44
Argentina	36
Brazil	25
Chile	17

Army Returns 114 Troop Ships to WSA

The War Department has scheduled the release of 114 troop ships to the War Shipping Administration in the first four months of 1946 for return to American and foreign owners, the San Francisco Port of Embarkation announces.

The release of these vessels by the Army Transportation Corps was made possible by the fact that the Army had discharged 1,665,000 more men by January 1, 1946, than had been planned under its demobilization program.

It is emphasized that troop ships remaining in Army and Navy service will be more than adequate to return the soldiers on the schedules announced by the General of the Army Dwight D. Eisenhower, Chief of Staff, in his statement to Congress on January 15.

The following list includes ships scheduled for release which sail in and out of Pacific Coast ports, their ownership, and tentative date of release to WSA for return to private control.

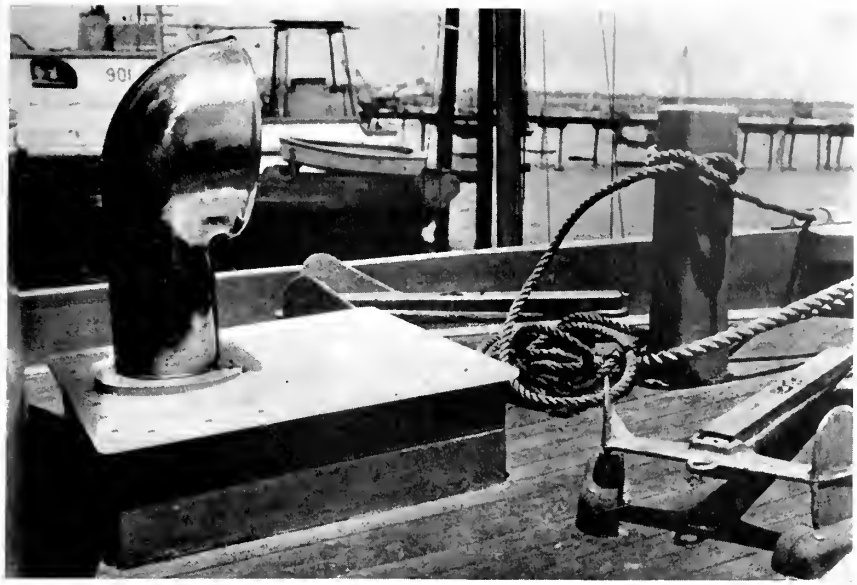
*The Yukon was wrecked off the Alaska Coast in February and is a total loss.



Plastic hatch covers, made of Plexiglas, appears for the first time in a fishing boat in the wheelhouse windows and forward hatch cover of the Poggy.

Plastic Hatch Covers, Windows, Used on Work Boats

Plexiglas, a transparent acrylic plastic, appears for the first time in a fishing boat in the wheelhouse windows and forward hatch cover of the Poggy, a 38-foot vessel built in San Diego. Though the plastic has been utilized before in pleasure craft, this is its initial entry into the commercial boat field.

The wheelhouse windows are made of ¼ inch Plexiglas; in the central window is a tiny "window within a window", hinged into the larger pane, which can be opened for greater vision during rough or foggy weather.

The forward hatch cover is of ¾ inch Plexiglas, sandblasted to make it translucent. This hatch cover is particularly successful because it diffuses light in such a way that there is more light below in the two forward bunks when the hatch is on than when it is off. This spreading of light rays means that the interior dries much faster, and dry rot is prevented. The hatch cover and windows were fabricated by Rohm & Haas in its Southgate, California plant, and attached in San Diego.

Towboat Engine Installation Establishes A Precedent

A new Type JS 8-cylinder supercharged Cooper-Bessemer diesel engine was installed in the towboat, Whayne H. of the Walter G. Hougland fleet at Paducah, Ky., recently without dismantling the engine or removing the boat's superstructure, marking the first time that such a large installation had been completed in this manner. (See illustration.)

Removal of the former engine and installation of the new one was completed in six weeks under the supervision of W. B. Hassell, port engineer of the Hougland fleet. The towboat's new power plant was given its initial test run off Paducah, October 17.

The engine, which weighs approximately 32 tons, was installed in this unusual manner because shipbuilders had advised that either the boat's superstructure would have to be almost entirely removed or the engine dismantled before the job could be completed. This meant that the boat would have been out of service for months at a time when river power was at a premium.

Mr. Hassell and his crew of workmen began their tremendous task by first dismantling the old power plant and pulling it through an opening which had been made flush with the deck at the location of the engine room by cutting out a small section of the side wall with welding torches. The side of a flat barge was also cut down so that the way would be clear to load it from the boat to the barge without interference. The barge was loaded with ballast to make it exactly flush with the towboat's deck. The engine was pulled out with hoists and wire rope and hauled to the barge. From there, the engine was loaded on a flatcar and taken back to the Hougland machine shop.

The new Cooper-Bessemer JS-8 supercharged diesel slips into the engine room by means of chain hoists, wire rope, some manpower and plenty of ingenuity on the part of Hougland's port engineer, W. B. Hassell.

Statehood For Hawaii

(Continued from page 261)

nal deaths for 1,000 living births had declined from 7 in 1932 to 1.6 in 1945.

46. That the venereal disease infection rate per 1,000 in Hawaii declined from 175 in 1911 to 7.5 in 1945. On the mainland the rate has declined from 163 in 1911 to approximately 43 in 1945. In Hawaii the locally acquired rate was 1.4 in 1945.

47. That according to the social security board, Hawaii's public assistance program is based on "liberal, progressive legislation." Hawaii has no maximum limitation of public assistance; and the Territory has thus placed itself in a position to make payments to needy individuals commensurate with need, and to give recognition to changes in living costs. Hawaii also has a medical and dental care program, and provides other forms of public assistance for which no Federal grants are given.

48. That in 1945 Hawaii ranked thirty-ninth in the average grant for old-age assistance, fifteenth in the average grant for aid to dependent children, thirty-fifth in average grant for aid to the blind, and fifteenth in the average grant for general assistance.

49. That the territorial legislature has enacted legislation comparable to that of many States. Hawaii has adopted 20 of the mainland uniform laws. In addition to laws mentioned above, Hawaii has a civil-service law, a modern retirement system for all employees. In the field of public health the Territory has enacted a crippled-children's act, created a bureau of mental hygiene, passed a uniform narcotic-drugs act, and established compulsory vaccination for smallpox, typhoid, and other diseases. In addition to the existing public medical-care program the legislature in 1945 provided for a study of health-insurance and hospital facilities. In 1935 the legislature created the Hawaii Housing Authority, passed the Federal Housing Act, authorizing the acquisition by any Federal agency of property suitable for housing projects, and an act entitled "Government Aid for Housing Projects" authorizing the Territory and its political subdivisions to aid in the planning, construction and operation of housing projects.

Recommendations

Therefore, since—

1. The people of the Territory of Hawaii have demonstrated beyond question not only their loyalty and patriotism but also their desire to assume the responsibility of statehood; and since

2. The policy of the United States Government is one of self-determination: that peoples be allowed to choose freely their form of political status; and since

3. Hawaii's strategic location in the Pacific plays so large a part in our country's international position in this area; and since

4. The Congress of the United States has through a series of acts and committee reports indicated to the people of the Territory that Hawaii would be admitted into the Union when qualified; and since

5. The Territory of Hawaii now meets the necessary requirements for statehood:

It is the recommendation of this subcommittee that the Committee on Territories give immediate consideration to legislation to admit Hawaii to statehood.

Henry D. Larcade, Jr.
Democrat, Louisana, Chairman,
James J. Delaney,
Democrat, New York
George P. Miller,

Homer D. Angell,
Republican, Oregon.
Dean P. Taylor,
Republican, New York.
Joseph R. Farrington,
Republican, Territory of Hawaii.

S. F. Chamber Is First to Urge Statehood for Hawaii

Immediate admission of the Territory of Hawaii to statehood was urged by the Board of Directors of the San Francisco Chamber of Commerce, which is the first chamber of commerce in the nation to take such action.

Asserting that Hawaii has fulfilled every qualification for statehood, the Board cited the Territory's well functioning, orderly government as evidence of Hawaii's capacity to conduct her own affairs.

Hawaii's self-sustaining economy and valuable resources and property also give her statehood status, the Board maintained. It was pointed out that the Territory has greater population than four states and a greater area than three states in the Union.

Though a Territory, Hawaii is subject to Federal taxation imposed on states, but without representation in Congress. Placing Hawaii on an equal footing with the other states of the United States would give the Territory fair representation and eliminate unfair discriminations, the Board stated.

From the military standpoint, the admission of Hawaii to statehood would have far-reaching international importance, for it would bind this strategic military base more closely to the United States, it was asserted.

Brayton Wilbur, president of the Chamber, pointed out that the admission of Hawaii would also have great social significance. "The heterogenous people of Hawaii have already demonstrated their ability to integrate their lives and interests into the American pattern by their harmonious relations and their loyalty to the United States during World War II," Wilbur said. "Admission of Hawaii to statehood would intensify that loyalty."

Mariners Club February luncheon guest was Jack Ruggles (at left) former Wing Commander of R.A.F., with President Tom Short and Louis Ets-Hokins.

Ex-RAF Pilot Guest of Mariners

A talk by Jack Ruggles, who piloted Winston Churchill's plane to vital wartime conferences, highlighted the program at the regular meeting of the Mariners Club of California, February 6.

Jack is one of those who joined the RAF before the United States entered the war. Assigned to the British Transport Command, he operated over many war areas, and was a member of the crew selected to pilot Churchill's B-29 to the Moscow Conference, and subsequently to carry the Prime Minister on his many war missions. His tales of the travels with the Prime Minister in the Middle East, European, and Russian territory were enjoyable.

Louis Ets-Hokin took the floor to briefly speak of the forthcoming membership drive. He requested that each member do his utmost to increase the Club's membership.

Scheduled to speak at the regular meeting was R. V. Winquist, vice president of General Steamship Corporation, Ltd., who was unexpectedly called to Washington, D. C. His speech, "The Shipping Outlook" was postponed to some future date.

The Sea Squatters—Club for Ditched Fliers

If you like adventure stories, watch the coat lapels of people you pass on the street and meet in trains. When you see a tiny gold sea gull sitting on a lapel, you know the wearer has a tale to tell, for he belongs to the world's strangest organization, The Sea Squatters Club.

Lapel pin of the Sea Squatters Club.

The idea of forming a club for survivors was born in the mind of John F. Kidde, president of Walter Kidde & Company, whose engineers designed the ingenious devices which transform a wad of fabric into a craft capable of crossing a storm-swept ocean. After hearing reports on their life-raft equipment, the idea came of banding the ditching survivors into a club after the war.

The only way one can join this ultra exclusive club is to endure one of life's most harrowing experiences: "ditch" an ailing airplane in the ocean, crawl into a bobbing life-raft —and live!

Twelve hundred American men and women now wear these sitting sea gull emblems, and most of them were earned on military flights. Among the emblem wearers are: Gregory "Pappy" Boyington, 34-plane Marine ace who ditched off Rabaul; Eddie Rickenbacker and his crew, who bobbed for 22 days in the trackless Pacific; Harold Dixon and his two companions who did a modern Captain Bligh odyssey by sailing 1000 miles in 34 days to a tiny atoll in the South Pacific. There are hundreds of other sagas of aerial shipwreck in Sea Squatter archives; even the tale of two comely girls who huddled with eight men in life-rafts, sailed to a barren shore and spun out a Robinson Crusoe existence until rescued.

USCG WILL LOAN ANTIQUATED LENSES

Coast Guard Headquarters, Washington, D. C., has put on loan status antiquated aids to navigation, lenses for museums, schools and maritime societies. Because of legal restrictions the USCG cannot dispose of them as a gift, but can loan them indefinitely to responsible institutions. Here a Coast Guardsman examines an old-style lighthouse lense. Further information can be obtained from Headquarters regarding the loan of these lenses.

Excellent War Record In Ship Joinery Installation

In 1937 James D. Tayler and Norman A. Proffitt organized the Pacific Sales and Equipment Company with headquarters in San Francisco, for the purpose of acting as manufacturers' agents on the Pacific Coast. While representing two of the more important companies, namely, the Aetna Marine Corporation and the Aetna Steel Products Corporation, they performed a most noteworthy service in the country's war effort.

Their chief activities comprised the design and installation of the joiner work, furniture, furnishings, insulation, ventilation and duct work, on all types of naval and merchant ships, in the yards of the Western Pipe and Steel Co., in San Francisco; the United Engineering Co., the General Engineering Co., the Pacific Bridge Co., and the Bethlehem Company's plant in Alameda. They performed similar work on naval vessels constructed in Napa at the shipyard of Basalt Rock Co., the Charleston Shipbuilding Corp., in Charleston, S. C., and the Lake Superior Shipbuilding Corp., at Superior, Wisconsin. In the Southern California territory they successfully handled jobs at the yards of the Los Angeles Shipbuilding & Dry Dock Co.; the Bethlehem Co., San Pedro Yard; and the U. S. Naval Drydocks at Terminal Island.

In addition they supplied similar types of materials and equipment to many other yards on the Pacific Coast.

At the present time they are handling all the activities of the Aetna Marine Corp., and the Aetna Steel Products Corp., on the Pacific Coast which includes the joinery, carpentry, furniture, ventilating, air conditioning and insulation work on the large new American President Liners, now in process of completion in the Alameda yard of the Bethlehem Steel Company.

In order to efficiently handle the business of the Pacific Sales and Equipment Company there was recently completed a new building which includes a modern service plant and administration quarters at 1245 - 22nd Street, San Francisco.

The new General Electric Supply headquarters in Portland, Oregon.

GENERAL ELECTRIC'S NEW OFFICE; STUDENT TOUR; P. C. CHANGES

General Electric Supply in New Quarters in Portland

The General Electric Supply Corporation in Portland has just opened the most streamlined quarters available to any of its branches in the country at 300 Northwest Fourteenth Street, corner of Everett. The Portland branch serves the states of Oregon and Washington in the northwest.

Covering an area of 60,000 square feet, the new GESCO building is equipped with probably the finest lighting system in the city. The display floor and offices enjoy 70 foot candles of fluorescent illumination, provided by troffers on 7 foot spacings. Each troffer utilizes Holophane "Controlens." All private offices, as well as the large offices accommodating the clerical assistants, have GE Germicidal Lamps installed for health protection. Offices and show rooms are completely air conditioned, including refrigerating compressors and heating. The top floor of the building, specially built by Timber Structures, Inc., has a free expanse 200 feet long by 100 feet in width. The roof is suspended from wall to wall, requiring no pillar obstruction, and in this respect is similar to the design used in dirigible hangars.

College Reporters Watch G. E.'s Wheels Go Around

The reconversion picture in the Bay Area got a thorough going-over when six college reporters on a tour of representative industrial firms visited the General Electric Oakland Works to get the inside story of just what college graduates can expect when they step out to start careers of their own.

Sponsored by the National Association of Manufacturers, two reporters from each of the daily newspapers at University of California, Stanford University and San Jose State College, made a tour of widely varied fields in Oakland and in San Francisco. The General Electric plant is one of eight representative concerns being covered by the reporters who plan to take back to their fellow students a fair and comprehensive picture of opportunities in industry in general.

The tour is similar to the recent "flying reporter" trip sponsored by NAM, which brought nationally prominent newsmen to the Pacific Coast to examine at first hand and write up their versions of the industrial picture in the west.

General Electric Changes in Pacific Coast Area

Two new Pacific Coast territory assignments were announced, effective as of January, 1946, by E. O. Shreve, vice president of the General Electric Company.

The Salt Lake City, Utah, trading area has been added to the present territory of R. M. Alvord, commercial vice president, San Francisco. A. S. Moody, commercial vice president, Portland, Oregon, will be responsible for the additional trading area of Butte, Montana, and immediate territory. Both men will continue to reside in San Francisco and Portland, respectively.

The Utah and Montana territories and administrative responsibilities have been added to present areas assigned to Mr. Alvord and Mr. Moody, upon the retirement after 41 years' service of A. L. Jones, G. E.'s commercial vice president in Denver. W. B. Clayton, commercial vice president, Dallas, Texas, has been assigned to Denver area, in addition to his present territory.

Two reporters from each of the Bay Area University dailies visited G.E. and saw recent 100 per cent war production of vital transformers and cables being reconverted to peacetime uses.

Welcome Aboard the S.S. Golden State

The Propeller Club Port of Los Angeles-Long Beach Board of Governor officers were extended an invitation aboard the S.S. Golden State at Long Beach, when she docked there on January 15. The invitation was given by Captain Claude B. Mayo, superintendent, California Maritime Academy. This vessel made a stop at Long Beach Harbor en route to Mexico and South American ports, destination Valparaiso, Chile. The occasion was much enjoyed by all attending.

Recently Captain Mayo announced the training ship had arrived at her destination and was visiting in Latin American waters.

Above: A new midshipman reports aboard the S.S. Golden State, as upperclassmen greet him eagerly.

Left: "Knock off" time aboard the cruising training ship is time to relax from work and studies.

Below, left: Reveille on the Golden State rouses all hands with a blast down the hatch.

Bottom, right: Captain Claude B. Mayo, USN (Ret.), superintendent of the California Maritime Academy, Carquinez Straits, Vallejo, California, addresses the school just prior to the S.S. Golden State's South American voyage.

NEW EQUIPMENT AND MACHINERY FOR YARD, SHIP AND DOCK

Specialists in Marine Paints

With the return of our merchant ships to their peacetime operators, the matter of economical repair, maintenance and conversion is one of considerable importance to the operating staffs. The wise selection of the proper quality of paint for use on every part of the ship, will eventually result in considerable savings in lay-up time for cleaning and painting.

What might be termed one of the most vexatious problems of the shipmaster is that of keeping the submerged portion of the ship's hull free from all types of marine growths. All sorts of barnacles and other forms of marine matter continue to foul the vessel's bottom, so that even the most active commercial vessels appear to suffer a 5 to 10 per cent loss in operating efficiency after nine months out of dry dock.

For well over a period of forty years the chemists and manufacturing staff of the American Marine Paint Company have studied the many problems involved in this marine field and are able to offer a line of marine paints which will guarantee satisfaction under the most trying sea-going conditions.

The company's Germicide Composition bottom paint is recognized as one of the leading standard brands throughout the United States and is manufactured to suit all conditions. The tropical anti-fouling composition is compounded to combat the trying conditions found in tropical waters. They also manufacture a supertropical antifouling composition which is especially suitable for the sides of the hull where grass as well as other marine growth is prevalent.

Yachtsmen have found their Triple "C" Cape Cod Copper Compound to be an outstanding bottom paint over many years.

Founded in 1903 by J. M. Botts for the purpose of specializing in the manufacture of marine paints the company's plant is situated at Bryant Street, San Francisco.

The officers of the company are John Parker, president, and Fred W. Blanch, vice president in charge of sales.

New Flame-Proofing Finish for Fabrics

One of America's wartime secrets, a revolutionary fabric flame-proofing finish for textiles known as Ban-Flame, was revealed by the Joseph Bancroft & Sons Company, Wilmington, Delaware.

When applied to textiles this remarkable finish confines the action of fire to the area contacted, prevents spreading of the flame and frees the fabric from any afterglow. Ban-Flame treated fabrics do not burn, they only char, and then only at the point of contact with an open flame.

Soon to be made available for civilian use through its own mills, as well as others licensed by Bancroft, this process is a solution to the fabric and textile fire hazard in the marine and industrial world.

On commercial vessels, pleasure craft, automobiles and airplanes, it meets the need for a combined flame-proof and mildew-proof finish for upholstery fabrics, folding furniture, curtains, draperies and materials which are exposed to water and dampness, for Ban-Flame has excellent mildew-proof qualities.

This new process is to be moderately-priced to manufacturers, making it possible to provide the public with combined flame-proof, mildew-proof fabrics without appreciable increase in cost.

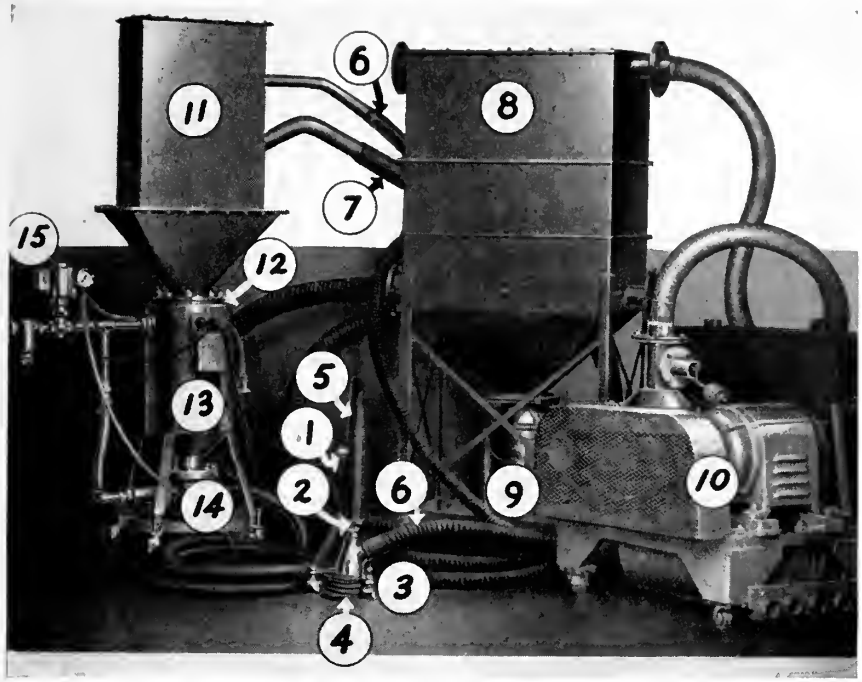
Packaged Line of Conveyors

A unique feature in the marketing of conveyors is the completely packaged line of gravity roller conveyors by Lyon Metal Products, Inc., of Aurora, Illinois.

These conveyors have great industrial use in handling and transportation of cartons, bales, packages, boxes, crates and other types of merchandise. They are available in these sizes:

Three straight sections all 10 feet long and in three widths, 12″, 18″ and 24″; three 90-degree curved sections, 12″, 18″, and 24″ wide; two trestles 18″ and 24″ wide. Each item is a complete unit, packaged and priced, simplifying selling, ordering and stocking.

The transportation on Lyon conveyors is by gravity, no power unit being needed.



1. Push button remote control switch. 2. Tungsten carbide nozzle. 3. Cast aluminum Vacu-Blaster gun. 4. Bristle brush in flexible retainer. 5. Blast hose with built-in electrical conductors. 6. Abrasive and debris vacuum return hose from gun to cleaner. 7. Dust and fines conveying hose from reclaimer to collector. 8. Dust and fines collector. 9. Dust and fines disposal bucket. 10. Vacuum pump unit with relief valve, motor, mufflers and cantroller. 11. Reclaimer and storage tank (250 lbs. grit capacity). 12. Automatic recharging valve. 13. Pressure abrasive feed tank. 14. Automatic feeding and flushing valve. 15. Magnetic operating valve and strainer.

The Vacu-Blaster

This equipment is being successfully used at the present time to remove paint, scale and rust from the decks and other steel surfaces of many ships in the San Francisco Bay Area.

It consists of a specially designed blasting gun, abrasive reclaimer, dust collector, abrasive storage tank, and vacuum pump unit. The gun consists of a blasting nozzle enclosed by a cone, which is surrounded by a pick-up cone, and further enclosed at the point of surface contact by a brush in a flexible retainer. The brush on the gun is held in contact with the surface to be cleaned, and the air stream from the vacuum return line effects a positive pickup of all dirt, dust and abrasive.

The Vacu-Blaster gun is operated with one hand, and is equipped with a push-button which controls the entire cycle of operation. While the surface to be cleaned is bombarded by steel grit from the blasting nozzle, the resultant refuse and spent grit are automatically picked up and returned to the abrasive reclaimer for separation—all in one continuous operation.

The Vacu-Blaster will thoroughly clean steel and many other surfaces without scattering any refuse or abrasive. It eliminates the need for protective clothing or artifically ventilated blast cleaning rooms; also effects a complete reclamation of re-usable abrasive.

The immediate application of paint to the cleaned surfaces, while blasting is going on on adjacent areas, is permissible.

The appliance is distributed by the Vacu-Blast Company of 272 Fremont Street, San Francisco 5.

Cummins Adds 200 and 275-HP. Diesels to Line

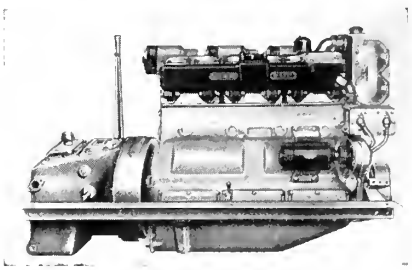
The Cummins Engine Company, Inc., of Columbus, Indiana, has announced the addition of two engines to its extensive line of marine diesels. The new high speed diesels are the Model NHM-600, with a maximum rating of 200 hp at 2100 rpm, and the supercharged Model NHMS-600, rated 275 hp (maximum) at 2100 rpm.

It is not strictly correct to term these two models of Cummins dependable diesels as "new" engines. Both were developed from the long proved and familiar Series H and supercharged HS, six cylinder diesels. The NHM-600 and NHMS-600 are merely higher horsepower, higher speed versions of the HM-600 and HMS-600 models. The increased capacities of the newly developed diesels were obtained by these three major innovations in the established Cummins design:

(1) By increasing the maximum operating speed from 1800 rpm (Models HM and HMS) to 2100 rpm (Models NHM and NHMS).

(2) By increasing size of the bore from 4⅞" to 5⅛", with corresponding increase in piston displacement from 672 to 743 cubic inches.

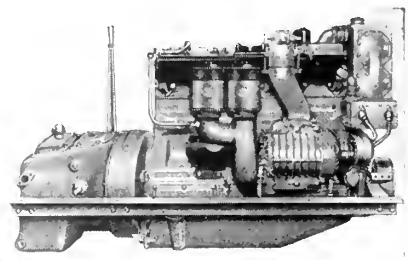
(3) The increased air supply needed to assure efficient combustion of the additional fuel required to produce increased horsepower is obtained by the use of dual intake valves. Dual exhaust valves permit the rapid exhausting of gases from the combustion chamber.



The generator side of the NHM-600 with standard equipment. The six-cylinder Model NHM produces 200 hp at 2100 rpm maximum, has 5⅛" bore and 6" stroke, 743 cubic inch displacement, dual intake and exhaust valves.

•

The supercharger side of the trim, lawweight supercharged Model NHMS - 600 Cummins marine diesel. Specificatians are: six cylinders, maximum rating 275 hp at 2100 rpm, 5⅛" bore and 6" stroke, 743 cubic inch displacement, dual intake and exhaust valves.



The photo shows G-40 Cherry Rivet Gun being used to install self-plugging Cherry Rivets in sheet metal. Note that the gun can be held and operated with one hand. It is well balanced for easy use in any position.

Cherry Blind Rivets

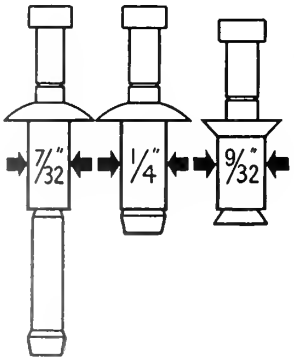
One of the wartime production techniques that has been immediately adopted by peacetime industries is blind riveting.

The practicability of using blind rivets in blind and difficult applications has been proved by their extensive use in military and commercial aircraft production, maintenance and repair. However, the conversion of this fastening technique to other industries has created new demands in blind rivet design and function.

To meet the need for larger diameter blind rivets, three new diameters, 7/32", 1/4" and 9/32" are now being manufactured by the Cherry Rivet Company of Los Angeles. These rivets are available in the three standard Cherry Rivet types, self-plugging, regular hollow and pull-through hollow; in modified brazier and 100° countersunk heads; in A17ST or 56S aluminum alloy, and in steel.

To install these larger rivets, a pneumatic-hydraulic Cherry Rivet gun, the G-40, is now being manufactured. It operates on from 75 to 90 pounds air line pressure, is 13 inches high and weighs seven pounds. The gun is well-balanced for easy one-hand use in any position.

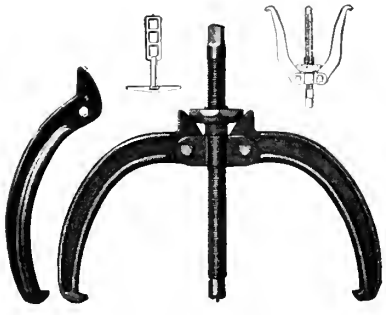
To meet the demand for larger blind fasteners, Cherry Blind Rivets are now manufactured in 7/32", 1/4" and 9/32" diameters, in addition to the 1/8", 5/32" and 3/16" diameters. All Cherry Rivets are available in the three standard types, self-plugging, regular hollow and pull-through hollow; in modified brazier or 100° countersunk heads; in a wide range of grip lengths and in several alloys. Special heads, grip lengths and alloys are made to order.



A Patented Puller for Propellers, Wheels, Pulleys and Gears

The Klay Puller, which is manufactured by The Scott & Ewing Company, Findley, Ohio, is an exclusive design in which the pulling and gripping actions are independent of each other. This puller is claimed to develop greater pulling power plus a safer and more positive grip on the object being pulled.

Not only does the Klay lock-nut principle securely lock the hooks to the gear or wheel so that they will not slip off, but the grip is equally applied on all sides. Thus the total force developed by Klay pulling screw is directed toward removing the wheel instead of part of it being diverted into gripping power.



In addition to regular straight and curved hooks, many types of special hooks are available and interchangeable for specific applications, including expansion hooks which work just the opposite from regular hooks. Klay Pullers are made in two and three-hook types for pulling anything from a 5/8" gear up to a 40" wheel or hub.

New Magnetic Contactor Announced by Westinghouse

For machine tool control, marine and mine application, and similar severe-duty applications where space is limited, a new type M d.c. single pole magnetic contactor is announced by the Westinghouse Electric Corporation.

Small, compact design of the new contactor saves panel space, and unit construction speeds assembly and assures accurate alignment of all parts. Rear or front-connected units are available. Contactor is entirely assembled on a formed frame which also serves as a path for the magnetic flux.

The small frame contactors in this line are limited to applications in which the coil voltage and the voltage of the circuit being interrupted do not exceed 250 volts. The deep frame contactors, which provide greater winding space for the operating coil, are suitable for voltage up to 600 volts.

Operating coils are rated for continuous duty and will operate the contactors at 80 per cent to 110 per cent of their rated voltage. The contacts are insulated for a maximum potential difference of 600 volts among parts.

New Roustabout Crane

The Hughes-Keenan Company, Mansfield, Ohio, has recently announced a powerful new roustabout crane, Model MC-8, which handles loads to 10 tons. It is a mobile full-swing boom crane, tractor mounted, that is easily driven where needed.

Booms of standard lengths from 15 to 30 feet are furnished; MC-8 is especially adapted to use of long booms, will handle loads of nearly 2 tons at a 30-foot radius, 10 tons at 9 feet. Ball bearing boom turntable and all gears and clutches run in oil, fully enclosed. Boom swing and hoist and load hoist are all independent actions, with separate controls and automatic brakes.

It is ruggedly built, designed for efficient operation, ideal for loading, unloading, moving or stacking heavy objects, especially outside the range of big overhead cranes, or where none are available.

SHORESIDE PERSONALITIES

New Officers of Transpacific Conference

ROY V. CROWDER is secretary of the Transpacific Conference in San Francisco, succeeding J. E. Wilson, who has been in the position for more than 24 years. Mr. Wilson will continue on in an advisory capacity. Crowder is the second ranking steamship man to be selected for a key post in Pacific Ocean shipping conference circles within the past month.

Only recently the Pacific Westbound Conference drafted HARRY HORNUNG, who had just returned from 39 months in the Southwest Pacific, with the rank of Colonel, when he was named secretary-manager of this body. Before the war he was freight traffic manager for N. Y. K.

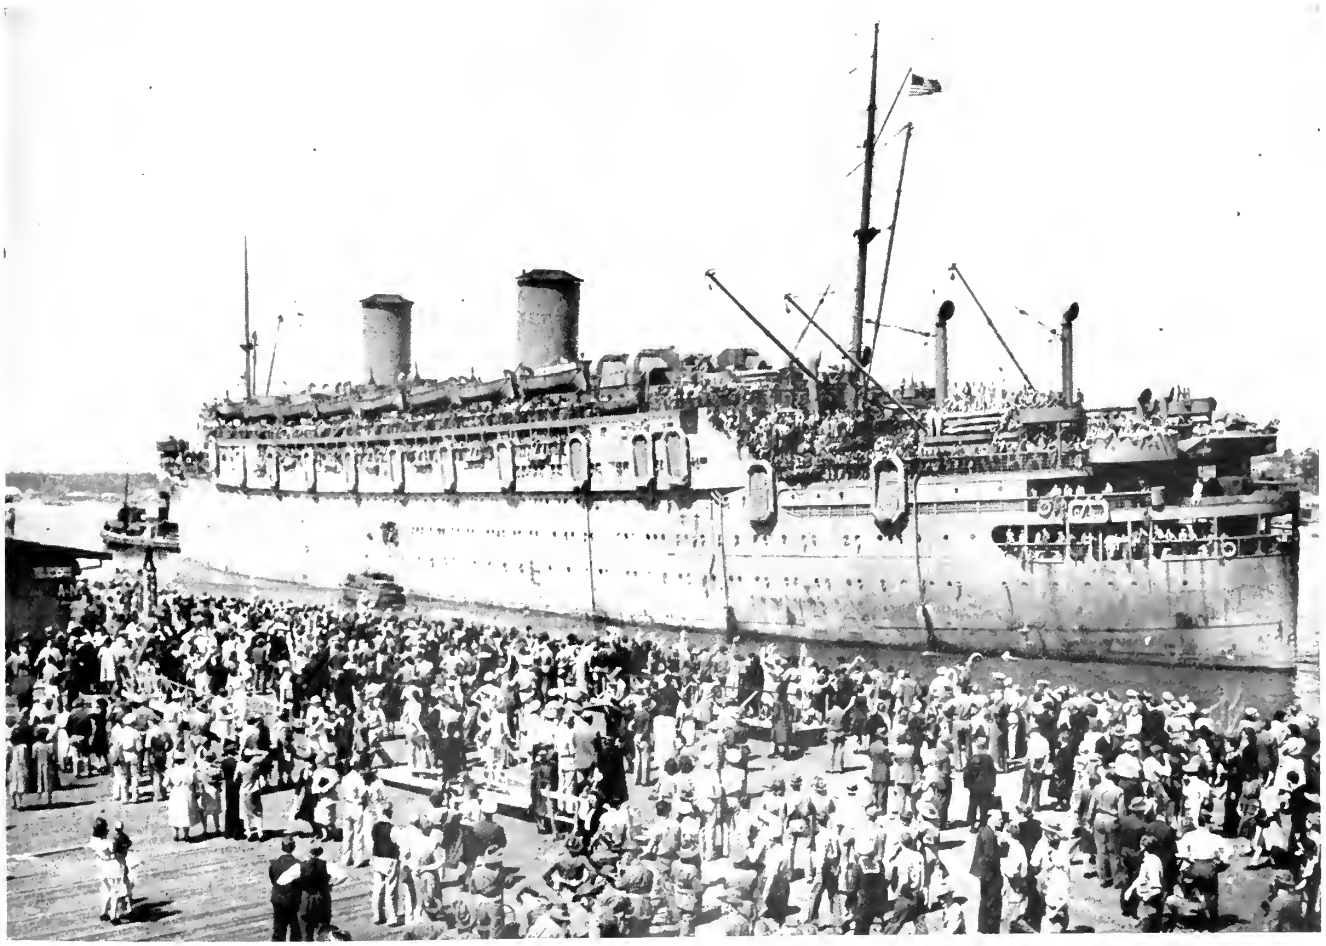
Crowder is remembered as passenger traffic manager for the Grace Line in New York and later in San Francisco. He was also one-time head of the passenger department of the Los Angeles Steamship Company, and was credited with much of the development and success of both their coastwise service with the Yale and Harvard, and the company's entry into the Los Angeles-Hawaiian passenger service with the liners City of Honolulu, City of Los Angeles, and the Calawaii.

Moved

Calmar Steamship in San Francisco shifted its pier offices from Pier 90 to Pier 48. This latter headquarters was recently turned back by the government.

Ever Hear of Merrill's Marauders?

In an address before San Francisco's Commonwealth Club, February 15, General Merrill stated that the Matson liner Lurline was selected to bring specially trained soldiers from the United States, pick up volunteer veterans from General MacArthur's forces in the South Pacific, and deliver them to India for the start of the ever-to-be-remembered raids of the Marauders behind the Jap lines in Burma. The Lurline (below) is about to be restored to Matson management for reconversion.



AGED LINER FINDS ... IN FAST G-E

(Right) G-E service engineer is shown grinding a set of collector rings for use in a 5400 kw marine generator. After being dressed down to close tolerances, the rings are shrunk on a mica sleeve, molded in one piece to cover the collector shell completely. Leads are silver-soldered to the rings. Exacting standards in work of this type are maintained by skilled G-E marine specialists.

(Left) George Barr, trained in marine engineering on the banks of the famous River Clyde in Scotland, is superintendent of General Electric's marine service in San Francisco. He joined G.E. in 1909 to work on turbines and has been closely associated with them ever since. During the last war, he supervised installation of main propulsion machinery in 46 destroyers. Since that time, he has played a large part in the development of geared-turbine and turbine-electric drives for every type of naval and commercial vessel. "Mr. Turbine," as he might well be called, has just hung up a record of 320 ships equipped with G-E turbine drives in the San Francisco area. Now it's his job to "keep 'em sailing."

FOUNTAIN OF YOUTH

KEEP 'EM SAILING SERVICE

REBUILT FROM SCRATCH IN 2 MONTHS, HER 27-YEAR-OLD TURBINES DUPLICATE THEIR TRIAL-RUN PERFORMANCE

A famous liner has served her time. Twenty-seven years of strenuous globe-trotting had left its mark—particularly on the ship's propulsion machinery. The two old turbines were so badly worn they gulped steam at an appalling rate and gave little in return. Leaking steam made the engine room unbearable. An important wartime mission demanded that they be rebuilt.

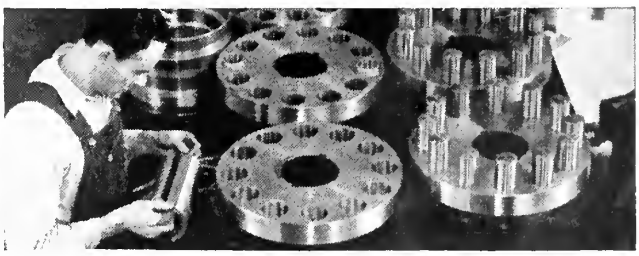
In a little over two months, this veteran liner was back at sea, her two rebuilt turbines turning up the same speed they made on their trial runs 27 years before!

A big job

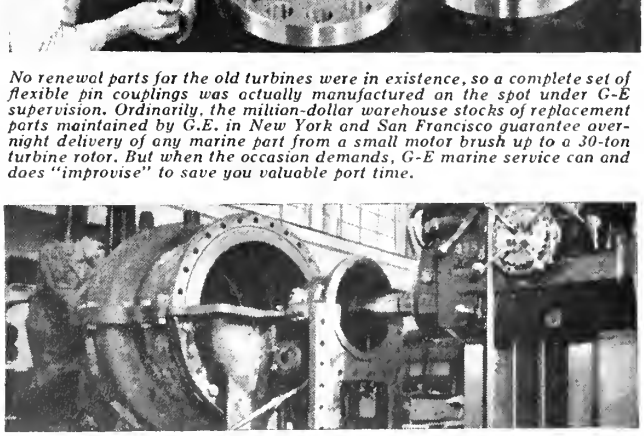
The turbines were so completely run down that only the casings, diaphragms, and rotors could be salvaged. For the rest, scores of renewal parts were needed; yet none was available. It was a big repair job—one which demonstrated dramatically the versatility of G-E keep 'em sailing service.

Working night and day, the General Engineering and Dry Dock Company, with the co-operation of G-E turbine engineers, literally manufactured the needed parts. Worn castings and shafts were metal sprayed and refinished. Turbine rotors were re-bucketed and re-balanced. Finally the reassembled turbines were tested; they developed their full normal rating *and they operated at their original efficiency!*

Another war story? Of course. But we think it makes a point which is just as vital to your peacetime operations. It is another fine example of the *flexibility* of G-E keep 'em sailing service—of G-E's ability to co-operate in speeding repairs *outside* its own service shops—of *expertness* in working on other than G-E equipment. We hope you'll call on this service freely to help cut port time and boost the earning power of *your* ships. *Apparatus Dept., General Electric Company, Schenectady 5, N. Y.*



No renewal parts for the old turbines were in existence, so a complete set of flexible pin couplings was actually manufactured on the spot under G-E supervision. Ordinarily, the million-dollar warehouse stocks of replacement parts maintained by G.E. in New York and San Francisco guarantee overnight delivery of any marine part from a small motor brush up to a 30-ton turbine rotor. But when the occasion demands, G-E marine service can and does "improvise" to save you valuable port time.



Producing a new turbine casing might take 6 months. This line couldn't wait that long, so the old casing was rebuilt from the ground up. Here it is being completely re-machined. Metal spraying, an up-to-date repair technique, is often used on jobs like this to salvage old equipment. The record shows that whenever the G-E marine organization was asked to rebuild a turbine, or to supervise such work, the resulting horsepower output equalled the manufacturer's original rating.

Moore Dry Dock Appoints Sandner

The Moore Dry Dock Company announces the appointment on February 1, 1946, of Victor R. Sandner as manager of their structural steel division. Sandner has been with the company since 1929, and previous to that time spent thirteen years on structural engineering work for engineers and architects in the bay area.

During World War II he was in charge of the structural steel department's operations on many important private and war contracts. The company is now furnishing, fabricating and erecting steel on numerous buildings and projects in connection with reconversion and plant expansion in the Western States.

American-Hawaiian-Luckenbach Joint Service

The American-Hawaiian Steamship Company and the Luckenbach Steamship Company, Inc., advise that in order to offer the most satisfactory service to shippers and consignees under reduced schedules, as recently advocated by the War Shipping Administration, they will, effective immediately, operate a joint service between Boston, Philadelphia and New York and Pacific Coast Ports with sailings, both eastbound and westbound, every five days. Luckenbach will continue to operate their independent service between the Pacific Coast and the Gulf, and American-Hawaiian will likewise continue their South Atlantic service on an independent basis.

Maritime Commission Construction Office Moves

The United States Maritime Commission announced that the office of the Director of Construction will be returned to Washington from New Orleans February 1. The construction headquarters have been in New Orleans since September 1, 1945. L. R. Sanford will continue as Director of Construction.

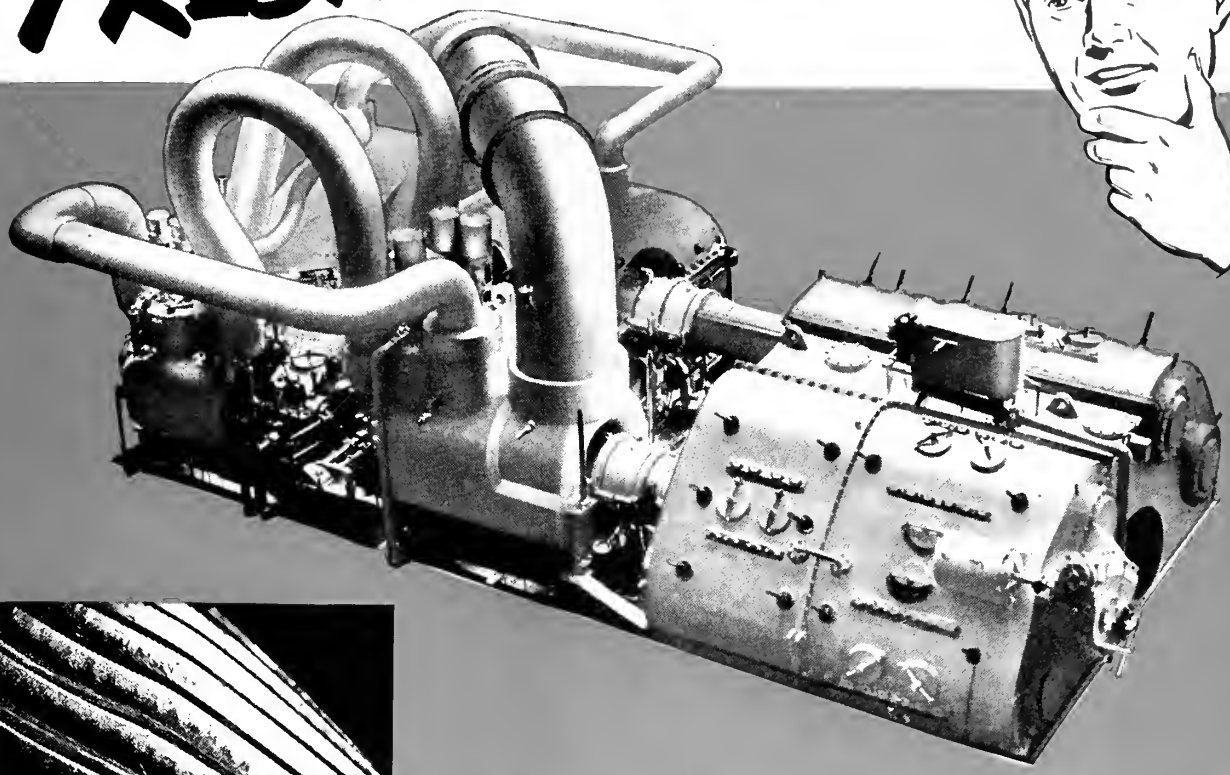
KEEP POSTED

Revolutionary Features in New Wire Rope Clamp

Cabl-ox, a new wire clamp, has been developed by the Nunn Manufacturing Company of Evanston, Ill., as the answer to the old problem of securing wire rope in its many applications.

This new product is the first step in reconversion by the Nunn organization. The Cabl-ox clamp, which has been tested by leading industrial laboratories, incorporates a new and exclusive wedging action in its component parts. This is the feature of the product which makes it possible to hold loads in excess of the tensile strength of the rope used. The unit is alloy steel, cadmium plated for weather protection, streamlined for neat appearance and freedom from obstruction. It is easily assembled or disassembled by unskilled labor. It is made in all standard sizes from 1/16" to 3/4".

TIME TO TAKE A FRESH START?



DON'T "INFECT" NEW TURBINE OIL BY PUTTING IT IN A DIRTY SYSTEM!

Upper photo—Because of improper cleaning methods, the oil in this system broke down completely after only six months of operation. Note severe wear on the gears caused by abrasive contaminants.

Lower photo—When Shell Marine Turbo Oil is used . . . following Shell Turbine Cleaning Procedure . . . gears remain clean and peak efficiency results.

SEND FOR THIS BOOKLET NOW!

Every turbine owner and operator should have a copy. It contains full details on the Shell Marine Turbo Cleaner and Shell Cleaning Procedure, and shows you how to get peak efficiency, lower operating costs.

SHELL CLEANING PROCEDURE

makes it easy . . . makes it sure!

A small amount of sludge and dirty oil acts on clean, new oil like a rampaging disease—can shorten its life 50% to 75%. Chemists call it the autocatalytic effect—sludge, metal particles and rust acting as catalysts to hasten the oxidation of new oil.

Before you add that next batch of make-up oil to your system, be sure to get details about Shell's Marine Turbo Cleaner and the Shell Cleaning Procedure. *You may decide to take a fresh start.*

Remember, too, this procedure should be followed before putting the first charge of lubricating oil in *new equipment.* As insurance, it's cheap enough to know that your turbine is free of slushing compound, run-in oil, and metal chips.

Call or write for your copy of the Turbine Cleaning Manual. Shell Oil Company, Incorporated, 50 West 50th St., New York 20, N. Y., or 100 Bush St., San Francisco 6, Calif.

SHELL

SHELL MARINE TURBO OIL

SPERRY GYROSCOPE COMPANY has published two beautifully bound publications, one on Electro-Mechanical Steering Systems, No. 19-10, the other on Gyro-Pilots, No. 19-15. Each is a complete treatise on its subject with photographs and outline drawings illustrating the text.

BAKER ARTICULATED FORK TRUCK is a four-page leaflet showing specifications and work possibilities of this handy truck. This leaflet is published by Baker Industrial Truck Division, of The Baker-Raulang Co., Cleveland, Ohio.

BETHLEHEM STEEL COMPANY has printed a beautifully illustrated booklet, No. 189, on the steel facilities on the Pacific Coast. The story of steel—through the operation of three steelmaking plants, three structural steel fabricating works and four mill depots in the four areas of the Pacific Coast by Bethlehem makes this booklet most interesting.

OAKITE-VAPOR HEAVY DUTY CLEANING UNIT is the title of a six-page brochure explaining the essential features of Oakite's new quality-engineered, multiple-duty steam cleaning unit for modern industrial plants.

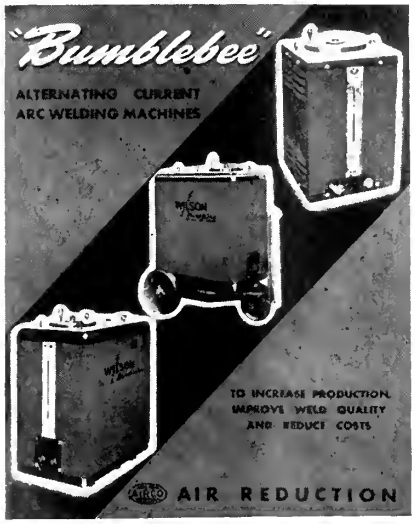
JESSOP STAINLESS STEELS, title of a specifications bulletin recently issued by Jessop Steel Company of Washington, Pa. It lists bars, hot rolled, cold drawn, centerless ground; billets, sheets, castings, circles, special shapes, plates, rings, flanged and dished head and other designs of steel.

PIONEERS IN INDUSTRY is the story of Fairbanks, Morse & Co. 1830-1945, told and illustrated in a beautiful book of 160 pages with elaborate four color treatment. From weighing devices through gasoline engines, windmills, pumps and gears to the most up-to-date diesel engines and airplane engines, this firm for 115 years has kept pace with the best practice and ethics in American industry. Today the company is on a very solid foundation of experience in its technical staff, integrity in its business dealings, and public confidence in its products. Our congratulations to the pioneers.

EVERLASTING VALVE COMPANY'S new 16-page bulletin No. E-150, explains the latest developments in lever-operated gate valves for industrial and other applications.

NEW A.C. ARC WELDING MACHINE BOOKLET: The new and improved Wilson "Bumblebee" alternating current transformer arc welding machines are fully described in a 16-page illustrated booklet, recently issued by Air Reduction, New York City. Engineering data and complete specifications are supplied and precisely labeled drawings and numerous photographs supplement the text.

The booklet describes the machines of 300 and 500 ampere standard and all-weather designs, and also the new 200-ampere "Bumblebee," which has been designed to meet the demands of a small arc welder, comparable in performance with the big "Bumblebees."



A SALUTE TO THE TUGS OF WAR has been made by Cleveland Diesel Engine Division of General Motors Corporation in a beautiful booklet called, "War Tugs Tell Tales of the Sea." The booklet contains a portion of the war records of several tugs powered by the company's diesel engines, and the facts presented are of vital importance to every shipbuilder, naval architect and vessel operator.

CELLULAR RUBBER: This four-page pamphlet, 845-21, published by Sponge Rubber Products Company of Shelton, Connecticut, describes various forms in which sponge rubber, bonded fiber and other sub-density materials are manufactured. Illustrated in the pamphlet are 98 molded, die cut and fabricated shapes of flexible, elastic, compressible products used for cushioning, shock absorption, vibration dampening, sealing, insulating and gasketing.

THE WATERTOWN BOOK OF PLASTICS is a new booklet issued by The Watertown Manufacturing Company of Watertown, Connecticut, that describes the company's complete service in plastics, including the development of Neillite, a phenolic-formaldehyde molding material. The booklet concisely explains the various thermosetting and thermoplastic materials that the company molds, and includes the new materials Saran, heat resistant Lucite, Cerex, Nylon and Polythylene. The booklet contains diagrams, graphs, illustrative photographs of custom molds in the commercial market, and a plastics properties chart.

SPRAY NOZZLES is the title of a sixteen page bulletin which sets forth and illustrates the Yarnell-Waring nozzles for water cooling, air conditioning and for general industrial uses in the catalogue issued by the Yarnall-Waring Company of Philadelphia, Pa.

HOW TO PUT OUT A MOTOR VEHICLE FIRE is the title of a cleverly illustrated, 24-page booklet and guide (which booklet should be tucked away in the glove compartment or similar handy location in all vehicles), issued by The General Detroit Corporation of Detroit, Mich.

is your boiler-water treatment COMPLETE?

HERE'S WHAT *COMPLETE* TREATMENT *MUST* INCLUDE

No. 3 in a series of advertisements on the requirements for the COMPLETE conditioning of boiling water.

1. Sound Chemical Treatment

(discussed in the February issue)

2. A Good Organic Coagulant

3. Simple But Scientific Control

(to be discussed in the April issue)

4. Competent Service & Instruction

(to be discussed in the May issue)

THE PRIMARY FUNCTIONS OF A GOOD ORGANIC COAGULANT ARE:

- **Maintain sludge in a "fluid" state to prevent adherence to heating surfaces.**
- **Eliminate carry-over by coagulation of suspended matter.**
- **Avoid costly blow-down through rapid settling of suspended matter and quick elimination by a short blow.**

BUT **— the finest coagulant is only ONE of the four requirements for COMPLETE boiler-water treatment.**

If you want to know how a real organic coagulant works hand in hand with chemical treatment, talk it over with the DREW Man—there's no obligation!

E. F. DREW & CO., INC.

15 East 26th Street, New York 10, N. Y.

Representatives in key cities in the United States, Canada, Mexico, Brazil and Porto Rico

COMPLETE AMEROID SERVICE is available in these principal seoports in the United States and Canada:

Portland, Maine; Providence, R. I.; Boston, Mass.; New York City; Philadelphia, Pa.; Baltimore, Md.; Norfolk, Va.; Wilmington, N. C.; Charleston, S. C.; Savannah, Ga.; Brunswick, Ga.; Jacksonville, Fla.; Tampa, Fla.; Panama City, Fla.; Mobile, Ala.; New Orleans, La.; Houston, Texas; Los Angeles, Calif.; San Francisco, Calif.; Portland, Oregon; Seattle, Wash.; Tacoma, Wash.; Montreal, Canada; Halifax, Nova Scotia; Vancouver, British Columbia.

AMEROID

THE COMPLETE BOILER-WATER TREATMENT

Hot Off the Press

NEW BULLETIN ON PORTABLE VACUUM CLEANERS: This 10-page bulletin is extensively illustrated with explanatory photographs showing a line of Exidust portable vacuum cleaners suited to the needs of almost every type of industrial plant, institution, transportation facility, and public or commercial building. The bulletin is issued by Allen Billmyre Company.

PUBLICATION NO. 3250 on High Pressure Condensate Return System is being distributed by The Cochrane Corporation in Philadelphia. Benefits derived from the use of this system, as described in the booklet, include the establishment of higher heat transfer rates, definite uniformity, and more heat from the same pressure of steam with less fuel costs and increased boiler capacity.

PLANE PORTRAITS, a 28-page booklet, illustrated in color, and published by Turco Products, Inc., Los Angeles, contains a series of articles published by the Editors of Air Tech magazine as a service to the Aviation Industry, and in recognition of the growing importance of chemistry in the care and maintenance of aircraft. The chemical processes and materials described are now available to help in solving production and maintenance problems in every industry. In addition to the technical data, Plane Portraits also contains 8" x 11" photographs, in color, of popular planes.

TAYLOR ISSUES REFRIGERATION CATALOG: With the great strides that have been made in refrigeration during the past few years has come an increasing need for proper and complete instrumentation. The Taylor Instrument Companies of Rochester, New York, has just published a 36-page catalog, No. 300, dealing exclusively with the application of control instruments to the refrigeration field. The catalog is divided conveniently into two sections, one covering applications—the other, instruments.

CLEMSON BROS. OFFERS HANDBOOK ON HACK SAW CARE: Selection of the proper blades for cutting various metals, causes and cures of common blade difficulties, and hints on "how and how not to do it," are featured in a new 30-page illustrated booklet offered by Clemson Bros., Inc., of Middletown, New York, manufacturers of Star hack saw blades. The booklet includes data on both hand and power blades, and recommendations apply to the blades of all manufacturers, except where the text states otherwise.

CROCKER-WHEELER BULLETIN DESCRIBES SEALED-POWER MOTORS: A four-page bulletin recently issued by the C-W Division of Joshua Hendy Iron Works, Ampere, N. J., describes the company's Sealedpower motor. An exclusive design, this motor was developed for use in industrial locations, in places where there is excessive moisture, and for all applications where the conventional alternating current, totally enclosed, fan-cooled motor has been used in the past. Also included in the bulletin is a cutaway view and pictures of six typical applications. Laboratory tests, made before the motor was placed on the market in 1941, are illustrated and described.

POPE & TALBOT, INC., have recently put out a brochure featuring the advantages of the San Francisco Bay Area, to acquaint business executives, manufacturers and shippers throughout the nation with the pertinent facts and high lights of the San Francisco Bay Area as a potential market for their products. This brochure on the Bay Area is one of a series on Pacific Coast Ports. Other brochures cover the Puget Sound, Columbia Empire and Southern California.

"WORTHINGTON VERTICAL TURBINE PUMPS and Their Typical Applications," is a bulletin No. H-450-B33 recently published by Worthington Pump and Machinery Corporation. The bulletin illustrates a few of the many services to which Worthington vertical turbine pumps may be applied. These pumps, originally designed and used for pumping from bored or drilled wells have, within recent years, been applied to a very wide variety of services in almost every industry.

"THE GAS TURBINE POWER PLANT NOW A REALITY," is the title of a concise treatise with clear cutaway drawings and photographs of the gas turbine, issued by the Elliott Company, Jeannette, Pa., where the organization has designed and built for the U. S. Navy the power gas turbine. Although still in its infancy, the gas turbine will become a popular power plant of the future in varied fields. This booklet introduces its readers to the mysteries of the Elliott power plant.

"THE ATOM OF BERYLLIUM" is an attractive two-color leaflet recently published by The Brush Beryllium Company, Cleveland, to give comprehensive information on the advantages and applications of beryllium, metal alloys and compounds. Of simple atomic structure, beryllium is the only light metal with a high melting point, and provides superior advantages for X-ray transmission and sound velocity.

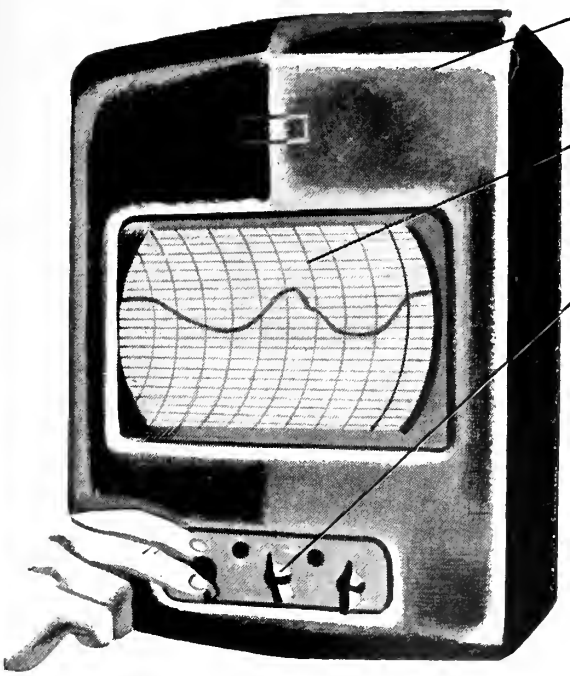
—fishermen everywhere acclaim the

NEW BENDIX-MARINE SUPERSONIC DEPTH-SOUNDER



compact, rugged, splash-proof

large horizontal unobstructed viewing window

low operating cost

The valuable contribution of the fishing industry to the welfare of the nation was never more apparent than during the past five years. Its reward has been substantial too, for today a greatly increased demand for fish and fish products exists everywhere.

Bendix-Marine* is proud to have an important part in supplying this vital commodity—for through the use of the Bendix-Marine Supersonic Depth-Sounder the taking of fish is now surer, quicker, safer than ever before. Everywhere fishermen are saying it is by far the most important addition to fishing equipment to come out of the war.

No other Depth-Sounder has all these features:

Lightweight • Portable • Lower First Cost • Easier Installation • No Relays Required • No Keying Adjustments • No Demagnetizing of Projectors • Uses Dry Recording Paper • Large Unobstructed Viewing Window • Horizontal Graphic Chart • Good Bottom Coverage at All Depths • Works on All Available Voltages • Graphic Recorder in One Compact Unit • Component Parts Are Accessible for Maintenance, Quickly and Simply Replaced.

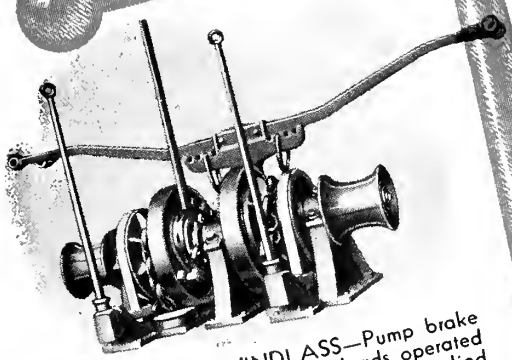
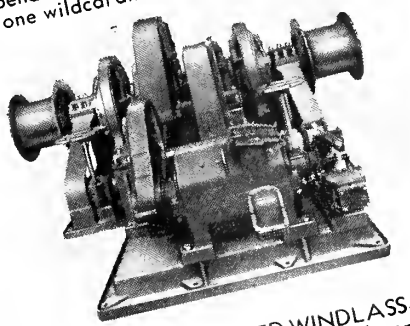
Æ Improves Windlass Manufacture for 1946

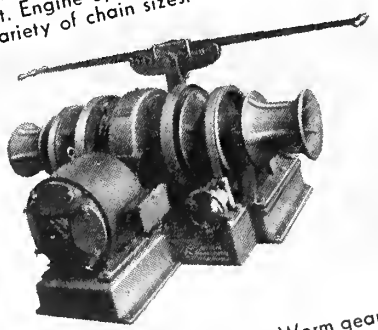


HAND POWER WINDLASS—Pump brake levers adjustable for power. Heads operated independently of wildcats. Can be supplied with one wildcat and one or two heads.

STEAM SPUR GEARED WINDLASS—Compound geared. Protected gearing and crankshaft. Engine cylinders close-centered. Built in a variety of chain sizes.



ELECTRIC SPUR GEARED WINDLASS—Water-tight variable speed motor and controller, protected gearing and brake. Warping heads on main or intermediate shaft.



ELECTRIC WINDLASS—Worm geared. Hand operation provided. Water-tight motor, variable speed controller, protective panel, resistors. Protected gearing. Also gasoline or Diesel drive.

Ask about quiet, compact electric types for passenger and passenger-cargo service

All of the familiar windlasses have been carefully developed over many years of experience. Only the best materials and expert craftsmen are used. Performance is dependable, long life is assured. You'll want all the information you can get on Æ windlasses—send for it.

When it's (Æ) . . it's A-1

Gulf Coast Representative: Sintes Sales Engineers, 332 So. Diamond Street, New Orleans 13, La.

Shoreside Personalities

Executive Director of Pacific American Steamship Ass'n.

Albert W. Gatov, well-known West Coast shipping executive currently with the War Shipping Administration at San Francisco, has been appointed executive director of the Pacific American Steamship Association, succeeding Lewis A. Lapham, who is returning to the American-Hawaiian Steamship Company.

This action was announced by E. Russell Lutz, president of the Association. Lapham's resignation and Gatov's succession become effective March 1.

Albert W. Gatov, executive director, Pacific American Steamship Ass'n.

The new director is 38 years old. Born in Southern California, he has been in the shipping business all his life, first with the Pacific Steamship Company, later as operating manager for the Interocean Steamship Corporation at Los Angeles.

Gatov was commissioned in the Army in January, 1942, and was stationed for the following two years at Fort Mason, San Francisco. In May, 1944, Gatov then a major, was sent to Basra, in the Persian Gulf Command, in charge of a transportation unit handling Russian Lend-Lease. He returned to California in July, 1945, and was released from service two months later.

In November, 1945, Gatov joined the San Francisco office of the WSA as assistant chief of traffic and allocations, the position he leaves for his new duties with Pacific American.

The association is comprised of sixteen major West Coast shipping companies and represents them in their collective dealings with various administrative branches, including the Maritime Commission, War Shipping Administration, Army and Navy.

W. L. Slattery Moves Up

William L. Slattery has been appointed a special assistant to the U. S. Maritime Commission. Since 1942 he has served as the Commission's general auditor of construction.

Pacific Coastwise Service Resumed

By David Gregory

Manager of Operations and Traffic
Olympic Steamship Co.

With the resumption of Pacific coastwise water service, the vessels and operations of Burns Steamship Company, James Griffiths & Sons, Inc., and Olympic Steamship Co., Inc., will be pooled to form an integrated service for the purpose of furnishing the shippers and consignees with a reliable and frequent service between the California ports of San Francisco and Los Angeles, (Long Beach) and Puget Sound ports of Seattle and Tacoma.

This service provides for weekly sailings commencing with the northbound departure of the MS Coastal Rambler from Los Angeles (Long Beach), Saturday, February 16; from San Francisco, Wednesday, February 20; and southbound from Seattle, Thursday, February 28. Following at weekly intervals and on the same weekday the MS Coastal Buccaneer and the MS Coastal Courser.

The method of integration which has been approved by the operators calls for all vessels departing from Los Angeles Harbor northbound to be berthed by the Burns Steamship Company. Olympic Steamship Co., Inc., will berth all vessels northbound from San Francisco. All vessels sailing southbound from Seattle and Tacoma for California ports will be berthed by James Griffiths & Sons,

David Gregory

Inc. In Seattle, Olympic Steamship Co., Inc., will serve as sub-agents for Burns Steamship Company. At the California ports, James Griffiths & Sons, Inc., has appointed Olympic as their sub-agents in San Francisco and Burns Steamship Company as their sub-agents in Los Angeles. Sub-agents for Olympic at Los Angeles will be Burns Steamship Company.

The vessels which have been assigned for this service by the WSA are modern CI-M-AV1 type vessels of approximately 5000 tons d. w. They are 339 feet long, diesel-powered, and capable of cruising at twelve knots. These motorships are considered ideal for the Coastwise general merchandise trade. Forward of the house there are three cargo compartments. Each compartment is equipped with 'tween decks. The 'tween decks will assure proper stowage with a minimum possibility of damage. The three forward holds are equipped with five sets of handling gear which will permit rapid loading and discharging. Each vessel is also equipped with a deep tank which may be utilized for freighting liquid cargoes in bulk.

An unusual feature of these vessels —something unique in the Coastwise service—is the 10,000 cubic feet of refrigerator space. This space is made up of three compartments. Any temperature from zero degrees on up may be maintained. Each compartment is independently controlled so as to permit a varied range of commodities to be shipped in accordance with the temperature requirements.

"Able-bodied"—

ABLE-BODIED implies more than a stout constitution. It means, to men at sea, the ability to perform many tasks proficiently. Seagoing men who earn that special rating are versatile.

Marine boilers, too, have to earn their rating the same way—through proved seaworthiness plus versatility.

That's why the B&W Single-Pass, Header-type Boiler is such a popular choice for Victory ships, C-1, C-2, C-3, C-4 and many other types of cargo vessels; for fast tankers, and ore carriers. B&W Boilers of the same design are also hard-working crew members on tugs and river craft.

This versatility is the result of years of cooperation between B&W marine engineers and shipbuilders and operators.

Together with long-lasting dependability and high operating efficiency, this proved adaptability to widely-varied marine services has earned for all types of B&W Marine Boilers the rating: "able-bodied".

BABCOCK & WILCOX

THE BABCOCK & WILCOX COMPANY
85 LIBERTY STREET, NEW YORK 6, N.Y.

On the Pacific Coast: C. C. MOORE & CO., 450 Mission Street, San Francisco, Calif.

Richard G. Coffin, manager of marine sales department, Socony-Vacuum Oil Co., Inc.

Coffin Moves Up At Socony

Richard G. Coffin, newly appointed marine sales manager of Socony-Vacuum Oil Company, Inc., has been associated with the company since January 1, 1926. He was first employed as a service station attendant by the White Star Refining Company in Detroit, and when White Star became a division of Socony-Vacuum, Mr. Coffin was made district sales manager in charge of Western Michigan and Northern Indiana.

In 1940 he was transferred to New York to be assistant to the general manager of the marine sales department, and successively became assistant manager of marine sales, domestic manager and, on January 1, 1946, manager.

Pacific Coast Manager

The appointment of Harvey A. Craig as Pacific Coast manager, Republic Steel Corporation, has been announced by J. M. Schlendorf, vice president in charge of sales.

In this new post, created to bring under one head the many sales problems peculiar to the Coast, Mr. Craig will supervise the territory served by all three Coast sales offices. He will, however, retain his position as manager of the Los Angeles office. No change is being made in the personnel of the other offices. W. L. Thomas is district sales manager of the San Francisco office and C. V. Gardner is district sales manager of the Seattle office.

Mr. Craig joined the organization in 1943 as manager of the Los Angeles sales office. For many years he was vice president of Rheem Manufacturing Company, Richmond, California.

USMS Discharge Button

The United States Maritime Service is now issuing a discharge lapel button, similar in significance to the emblem issued to former members of the Armed Forces.

Resembling closely the one worn by Army, Navy and Marine veterans, the gold-plated pin shows an eagle with his talons entwined about an anchor, with a laurel wreath encompassing the central figure.

Applications for the emblems may be secured at Maritime Service and War Shipping Administration offices.

New President of American Mail Line

A. R. Lintner, who was formerly vice president and general manager of the company, is now president and general manager of American Mail Line. Lawrence Calvert, president of American Mail since its organization in April, 1940, has resigned because of pressure of other business.

Lintner is a former Pacific Coast director of the War Shipping Administration, and previously was Pacific Northwest manager of WSA. He was Seattle district director of the United States Shipping Board during the First World War. He came to Seattle in 1917 from New York City, where he was with the Navy's construction department. After a year with Seattle Construction & Dry Dock Company, he joined the steel-ship division of the Fleet Corporation of the Shipping Board.

Lintner spent six years in the Orient representing the States Steamship Company.

Standard of California New V. P.

Election of C. E. Finney, Jr., as a vice president of Standard of California is announced by R. G. Follis, president of Standard.

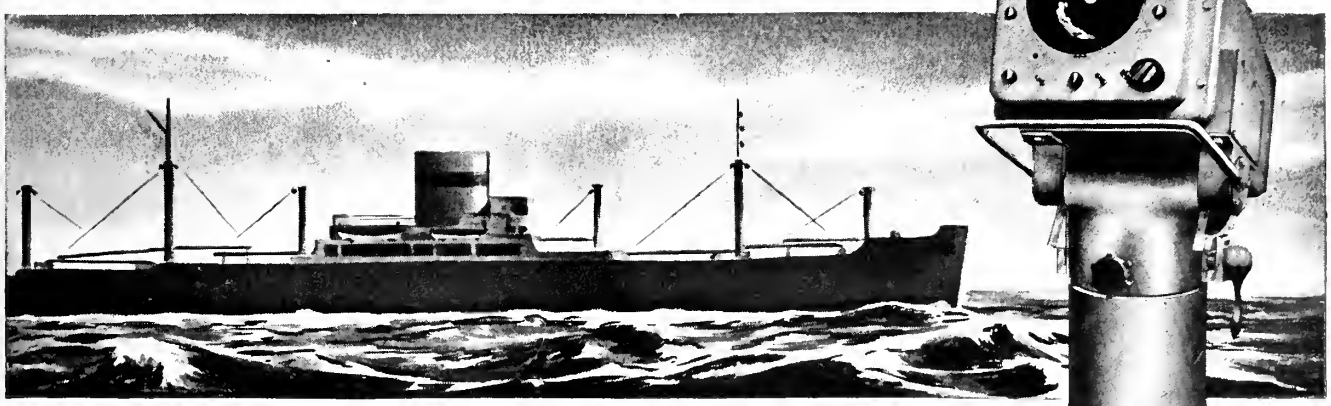
Finney has been assistant vice president for manufacturing for the last year. He will be concerned with industrial relations matters in his new position.

A graduate of Cornell University, Finney joined Standard of California in 1919 at the company's refinery in Richmond, Calif., and soon rose to pressure still foreman. In 1931 he became manager of the El Paso refinery of Standard of Texas, a subsidary, and a year and a half later was made manager of the Richmond refinery. Three years ago Finney became general manager of Standard of California's manufacturing department.

Two other new appointments in Standard of California's Manufacturing Department are G. H. Langsdorf as manager, Technical Services, and O. N. Miller, assistant to G. A. Davidson, vice president in charge of manufacturing. Miller formerly was superintendent of the cracking division at El Segundo refinery.

PROVED

on America's Fighting Ships



READY

for America's Merchant Ships

The INDICATOR can be mounted on the bridge—on deck, bulkhead, or overhead. Note that the head is rotatable vertically and horizontally through 45°... *adjustable* for greatest comfort and convenience!

RAYTHEON RADAR... *The "Mariners Pathfinder"* ... is ready for action! The design is frozen. Production is getting underway. Raytheon will soon begin equipping America's merchant fleet.

The same basic gear that served the Navy as the SG or SO radar has been re-designed in commercial form for the maritime industry. The same proved performance can be counted on! The same skill and experience in manufacturing Navy equipment will go into every set.

Here are some of the highlights of the new gear: range, 50 miles, or down to 100 yards ... true or relative bearings ... easy, convenient controls, *all* on the bridge indicator ... quick access to all components for maintenance and inspection.

This is the radar you will want—the radar that you *know* is "right" from the start. Remember—Raytheon is *the name that means most* in surface-search radar. Write or wire to Marine Department, 107 Foundry Avenue, Waltham 54, Mass.

Personnel Changes at Yarnall-Waring Co.

Yarnall-Waring Company, Philadelphia, announces the following personnel changes: **Joseph Kildare** has been appointed sales manager at home office; **Frank W. Miller** has been made works manager, and **J. Frank Long** has been transferred to Chicago district office as sales engineer.

Charles H. Grosjean, sales engineer in New York office, is now in charge of the Detroit sales office, replacing **C. N. Maxfield,** who has been appointed California district manager, with new sales offices in San Francisco and Los Angeles.

Two men have been added to Yarway sales staff; **Jackson Kemper,** New York office, and **Jack Schuyler,** Los Angeles office. Both of these sales engineers have had long experience in selling and servicing steam plant equipment.

Paul H. Bordwell, vice president in charge of Orient, for APL.

APL's New Oriental Vice President

Oscar G. Steen, vice president in charge of the Orient for the American President Lines, has resigned his position effective March 1, next, it was announced by Dr. Henry F. Grady, president.

Mr. Steen, a veteran of 33 years service with the American President Lines and predecessor companies, is leaving the steamship business to head up a company in Shanghai which will have the distributorship for Dodge trucks and automobiles.

Upon acceptance "with deep regret" of Mr. Steen's resignation, the President Lines' board of directors promptly elected **Paul H. Bordwell,** Mr. Steen's long-time assistant in the Orient, as his successor with the title Vice President in Charge of the Orient.

Mr. Bordwell is a native of Alameda, California, and like Mr. Steen is a veteran of more than 30 years service with the company in the Far East. He is widely and favorably known to the shipping industry on both sides of the Pacific.

In October, 1941, just two months before Pearl Harbor, Mr. Bordwell came to America on home leave. Unable to return to the Orient, he served as an executive assistant in the San Francisco home office, and lately he has been engaged in reorganizing the Oriental staff for resumption of company services in the Far East.

No "Blank Cartridges" in Admiral Vickery's Belt

Vice Admiral Howard L. Vickery received the welding industry's highest award, the James Turner Morehead Medal, at a dinner in New York January 28, attended by most of the heads of the Maritime shipyards in the country. This medal was presented to Admiral Vickery, former vice chairman of the U. S. Maritime Commission, for his outstanding services in building America's bridge of welded ships. Vice Admiral Emory S. Land, his former chief, also paid tribute to Admiral Vickery for his leadership in adapting the use of oxy-acetylene welding and cutting processes to quantity production of America's wartime merchant fleet.

Charles DeWolf Gibson, vice president of the Air Reduction Company and former president of the International Acetylene Association, presided, and in introducing Admiral Vickery said of him, "He never fired a blank cartridge in his life."

In the photograph left to right are: Mr. Gibson, Admiral Howard L. Vickery, G. L. Carter, I. A. A. president, and Admiral Emory S. Land.

Marine Exchanges Issues New List of Buyers

The Marine Exchange of San Francisco has prepared for its members a list of purchasers of material, equipment and services for steamship companies and shipyards of the San Francisco Bay Area.

The list, newly revised, indicates those in charge of operating, repair and subsistence matters.

Congress Committee Approves Kings Point Academy Expansion

The U. S. Merchant Marine Cadet Corps was created prior to the war under provisions of the Merchant Marine Act, 1936, as amended, and the site at Kings Point acquired for the construction of a permanent Merchant Marine Academy.

From 1938 to December 1, 1945, 7291 officers were graduated from the Cadet Corps for service with the U. S. Navy or attached to merchant vessels.

The members of a Congressional Board of visitors has reported to Congress that they were impressed with the splendid establishment at Kings Point, the highly efficient educational program and the fine type of young men participating. They further pointed out that the security and position of the United States in the field of international commerce and status as a sea power is largely dependent upon the character and education of officer personnel.

Recognizing the necessity for an expansion of facilities if the ultimate aims and objectives for which the Academy was created are to be realized, the Board recommended that adequate funds for a chapel, library, and development of athletic and recreational facilities be made available.

In accordance with recommendations of the Board, the course of study at the Academy has been extended to four years and measures are being taken to have the Academy placed upon an accredited basis permitting the award of a B. S. degree in Marine Transportation.

P. H. Lair, well-known engineer named New York sales manager by The Dampney Company of America.

P. H. Lair Named New York Sales Manager

The Dampney Company of America, Boston, announces the appointment of P. H. Lair, well-known Eastern industrial engineer and research consultant, as manager of its New York sales office, 114 Liberty Street, N. Y., where he will offer consultation and service in the field of protective coatings. Mr. Lair's experience fits him particularly for this position. For the past five years, he has been engaged in industrial and mechanical engineering for one of the larger Eastern engineering firms where he handled the design for several steam generating plants and steam distribution systems utilizing pressures as high as 1350 psi with 900F. total temperature.

Left to right: Jack Ellsworth, Jack Green, and Tom Pike, recent Tube Turns appointments.

Tube Turns Detroit Office and Head Office Appointments

Tube Turns, Inc., Louisville, Ky., has opened an office in Detroit, at 713 Ford Bldg., in charge of **Jack Ellsworth,** it is announced by John G. Seiler, the firm's vice president and general sales manager. Ellsworth will represent Tube Turns' forging and welding fittings divisions, and his territory will include Michigan, Northeastern Ohio, North Illinois, and Indiana, except Whiting and East Chicago. Before assuming his new post, he was assistant district manager of the Midwest territory, with headquarters in Chicago.

Mr. Seiler also made the following appointments: **Jack Green** is now sales manager of the welding fittings division. A native of Louisville, he attended the University of Kentucky and was the American Radiator and Standard Sanitary Corporation's branch manager in Mansfield and Akron, Ohio, before his affiliation with Tube Turns in February, 1941. He was stationed in Chicago, as district manager, before becoming the division's assistant sales manager in June, 1943.

Succeeding Jack Green as assistant sales manager of the welding fittings division is **Tom Pike.** He is a specialist in refinery and oil well equipment. Determined to learn the petroleum industry literally from the ground up, his first job was as a "roughneck" in the Huntington Beach oil field in California, his native state. Later he became an engineer-salesman for W. R. Guiberson Company before taking over Tube Turns' Los Angeles office, in January, 1940. He subsequently became district manager in charge of the West Coast territory.

Matson Line—New Southern California Headquarters

The Matson Navigation Company has moved from the Roosevelt Building in Los Angeles to the Pacific Mutual Building.

Ralph J. Chandler, vice president of Matson, is in Room 1235, 523 West Sixth Street; **Charles S. Booth,** assistant general freight agent, of Matson, is located at 550 South Grand Avenue; and Paul N. Carter, freight agent, Matson, is located at 550 South Grand Avenue.

The new passenger office is to be located at 533 West Sixth Street, Los Angeles, and an announcement of the opening will be made later, following completion of alterations.

Rear Admiral Friedell Retires from Service

Rear Admiral W. L. Friedell, Commandant of the 11th Naval District and former Mare Island Navy Yard Commandant, is retiring from service. He is being succeeded by Vice Admiral Jesse B. Oldendorf, commander of the battleships of a task force in World War II.

Matson's Director of Industrial Relations

Appointment of Alfred B. Tichenor as director of Industrial Relations of Matson Navigation Company and United Engineering Company was announced jointly by Frazer A. Bailey, Matson president, and W. P. Roth, chairman of the board, United Engineering Company.

Prior to his joining Matson, Mr. Tichenor was associated with Industrial Relations Counselors, Inc., of New York.

Kinney Names Manager of P. C. Branch

Roy A. Woltman has been appointed manager of the Pacific Coast branch for Kinney Manufacturing Company of Boston, Mass., and will also continue in charge of the company's office at Los Angeles.

Woltman succeeds Dean J. Hill, who died January 16 after 39 years with the Kinney Company. Mr. Hill opened the company's Los Angeles branch in 1922, and was appointed Pacific Coast manager in 1932, which position he held until his death.

Merchandising Manager Of Jorgensen Steel

Alexander H. Gaal has been appointed merchandising manager of the Earle M. Jorgensen Co., steel distributors, with warehouses in Los Angeles, Oakland and Houston.

Alexander H. Gaal, merchandising manager, Earle M. Jorgensen Co.

A discharged Army Major, he has been stationed for over three years in the Steel Division of the War Production Board, Washington, D. C. During 1943 he accompanied Sir John Duncanson, Steel Controller for Great Britain, on an extensive steel survey throughout the British Empire at which time the CMP plan was installed in Australia, New Zealand, India and Union of South Africa.

SALES REPRESENTATIVE WANTED: Thirty-four year old manufacturer of marine and industrial equipment wants to secure services of established individual or firm as sales agent for Pacific Coast. Profitable line for anyone familiar with marine trade. Please write to Box 346B, Pacific Marine Review, 500 Sansome Street, San Francisco 11, California.

Prior to his service in the Army he was with Republic Steel Corporation, general sales, Cleveland, Ohio, and also represented them in Los Angeles for several years. Mr. Gaal is a graduate of Mercersburg Academy, Ohio State University, and Harvard Graduate Business School.

United States
Treasury Department

January 25, 1946

Dear Mr. Editor:

On behalf of the Treasury's War Finance Committee of Northern California, let me take this opportunity of thanking you for your very splendid cooperation during the seven war loan drives and the final Victory Loan campaign.

We are thoroughly cognizant of the patriotic and unselfish efforts which you made during these drives, all of them so very vital to the successful termination of World War II and the preparation for a post-war world at peace.

You can rightfully take credit for a substantial contribution to the winning of the war, and for your service the War Finance Committee again extends its full measure of gratitude.

Sincerely yours,
EUGENE B. BLOCK,
Chairman, Press Division, United States Treasury Department.

Colonel Leon J. Lancaster, newly-appointed APL's general agent for the Northwest, with headquarters in Seattle.

APL Personnel Appointments

In preparation for his company's early resumption of full-scale commercial operations, Dr. Henry F. Grady, president of the American President Lines, announced a number of key personnel appointments in this company's worldwide shipping organizations. The appointees, still on terminal leave, are all former APL staff members who have been with the Armed Forces or on loan to the Government in civilian capacity. They are:

Colonel Leon J. Lancaster, general agent, Seattle, Washington; Colonel John T. Danaher, general passenger agent, New York City; Lt. Colonel James H. Whitman, general agent for the Mediterranean, with headquarters at Genoa; Commander Harold S. Campbell, general agent, Honolulu, T. H.; and Jay J. Murphy, returning from WSA assignment in Pacific, general agent, Boston, Mass.

Whitman, Campbell and Murphy are all products of the company's own Training System, having joined the organization as trainees on leaving college. They advanced through various departments and climaxed their training by serving as pursers on several President Line vessels.

Dr. Grady also announced the elevation of E. V. Nevin, chief auditor, to the position of executive assistant, on the San Francisco headquarters staff.

Jay J. Murphy, general agent, Boston, Mass.

Harold S. Campbell, general agent at Honolulu, T. H.

Commodore Norman B. Hall, USCG. Commodore Halert C. Shepheard (at right), USCGR.

Reassignment of Two USCG Commodores

Coast Guard Headquarters, Washington, D. C., announces the reassignment of Commodore Halert C. Shepheard as chief of the Merchant Vessel Inspection Division, Coast Guard Headquarters, Washington, D. C. Commodore Shepheard relieves Commodore Norman B. Hall, who returns to his regular Coast Guard duties.

During World War II, Commodore Shepheard was assigned duties where his years of merchant marine experience would be of greatest benefit to the maritime industry and the nation. Soon after the duties of the Bureau of Marine Inspection and Navigation were transferred to the Coast Guard in 1942, he was commissioned Captain in the Coast Guard Reserve, and became chief of the Merchant Marine Inspection Division, Coast Guard Headquarters, Washington, D. C. In June, 1944, he was temporarily detached from Headquarters for duty in the European war zone, where he served with the Commander, U. S. Naval Forces in Europe, and with the Supreme Commander, Allied Expeditionary Force. Detached early in 1945 he was promoted to Commodore, and continued on special assignments for the Commandant on merchant marine affairs, such assignments taking him to Copenhagen in November, where he was assigned as an adviser to the U. S. Delegate to the Maritime Preparatory Technical Conference of the International Labor Organization.

Coast Guard Headquarters announces the reassignment of Commodore Norman B. Hall, USCG, to his regular peacetime duties of Inspector-in-Chief of the U. S. Coast Guard, where he will have supervision of inspection of personnel, materiel, operations and financial transactions of the Coast Guard, to insure the efficiency and adequacy of Service functions. He will relinquish his present duties as chief of the Merchant Vessel Inspection Division to Commodore H. E. Shepheard, USC GR.

During World War II, Commodore Hall organized and had jurisdiction of the Coast Guard's wartime Port Security Division. While Chief of the Port Security Division he also acted as Coast Guard liaison representative to cooperate with the Facility Security Division, Office of the Petroleum Coordinator for war. For his outstanding work as Chief of the Port Security Division, Commodore Hall was awarded the Legion of Merit.

In July, 1945, he was appointed Chief of the Merchant Vessel Inspection Division of the Coast Guard, a position which he has held until the present date.

SHORESIDE PERSONALITIES

COLONEL WARREN D. LAMPORT, former director of operations at Vancouver, Wash., has taken over the duties of general manager of the Seattle port, succeeding the late Colonel W. C. Bickford.

Colonel Lamport was a one-time member of the Board of Harbor Commissioners of Long Beach, and president of the California Association of Port Authorities as well as a director of the California Association of Port Authorities.

In the appointment of Colonel Lamport, E. H. Savage, president of the Seattle Commission, announced that George Treadwell, who has rendered such outstanding service over the years, is now chief engineer, having been promoted from first assistant. Mr. Treadwell is well known and highly regarded among his colleagues on the Pacific Coast.

EDWARD "ED" PELTRET, well known as marine editor of the San Francisco Chronicle as well as a magazine writer until he resigned in 1938, has returned as shipping editor of the Call-Bulletin. During the war, he served as purser on vessels operating to Alaska out of Seattle.

SHORESIDE PERSONALITIES

R. W. HURLBUT, sales manager of Maritime Laboratories of Compton, Calif., manufacturers of Lectrolox and a complete line of marine paints, announces the recent appointments of the following distributors: for Alaska and Washington, Bryant's Marina, Inc., 117 East North Lake Street, Seattle; for Oregon, Steckmest & Co., Inc., 355 W. First Avenue, Portland.

The California distributors are: the Johnson Specialty Co., 27 Pine Street, San Francisco, for the northern part of the state; and for Southern California, the same company, located at 808 E. Anaheim, Wilmington; also at 2019 Main Street, San Diego. The Davis Service Co., of 621 Mission Street, San Francisco, represents the company in the Hawaiian Islands with offices at 313 Alexander & Baldwin Bldg., Honolulu and in the Philippines at the Philipinos Bldg., 21 Plaza Moraga, Manila.

THE DISTINGUISHED SERVICE MEDAL, highest award in the Merchant Marine, has been awarded Captain Hugh Parks Brown, Jr., resident of San Francisco and one of the youngest skippers in the service. This award by the War Shipping Administration was given to Captain Brown for his action while master of the SS City of Alma, in risking his life to save several members of his crew when his ship was torpedoed by a Nazi submarine.

OBIT: W. L. "Leslie" Comyn, 65, colorful personality in Pacific Coast shipping for more than 35 years and remembered as the leading figure in the building of the concrete steamer Faith, built and launched in the first World War near Redwood City, passed away in Seattle early in February, after a brief illness.

Mr. Comyn, while operating the firm of Comyn, MacCall & Company, had a number of sailing ships operating in the South Seas copra trade to San Francisco for many years. He has been engaged in the stevedoring and general steamship business in Puget Sound since leaving San Francisco shipping activities in 1939.

THE MARITIME COMMISSION has before it for study a reported proposed increase from $2500 to $5000 for admission of steamship lines into the Pacific Coast-European Conference, as submitted by that body.

It was reported that the Commission, which has jurisdiction over steamship combinations established under the Shipping Act of 1916, will fully investigate reasons for the submitted fee increase before any authority before such a scale is granted.

Member lines of the Conference include Blue Star Line, Donaldson Line, East Asiatic Company, Fred Olsen Line, Fruit Express Line, Furness Line, Isthmian Steamship Company, Knutsen Line, Lauritzen Line, Mosvold Line, Holland-American Line, Johnson Line, Royal Mail Lines and Interocean Line (Westfal Larsen & Company).

COMMANDER RALPH M. SHEAF, who was in charge of and directed the building of the U. S. Maritime Commission Training Station at Coyote Point, San Mateo County, is now attached to Kings Point Academy, New York, under Rear Admiral Giles Stedman.

Commander Sheaf is well known in the San Francisco Bay area. Hundreds of youths were trained under his supervision and are now officers in the merchant marine.

J. J. LOWE BACK WITH AMERICAN MFG. CO. — After four years of active duty with the Navy in European and Pacific areas, James J. Lowe, former Lieutenant, USNR, has rejoined the sales staff of American Manufacturing Company, Brooklyn, New York, cordage mill. In addition to field sales work, Mr. Lowe will direct the company's advertising activities.

GE's Federal & Marine Section Expands

Announcement has just been made by General Electric Company's San Francisco office of the appointment of **Hughes W. Ogilvie** as sales engineer in the Federal & Marine Section. He will make his headquarters in San Francisco, assisting **G. L. Crow** and **C. M. LeCount.**

Hughes W. Ogilvie, sales engineer in San Francisco for G. E.'s Federal & Marine Section.

A native of Memphis, Tennessee, Ogilvie graduated from Leland Stanford University in 1941. He joined General Electric in 1942 at Schenectady, N. Y. headquarters, taking the G E test course for engineers. He transferred to the San Francisco office the following year, where he has been field engineer on marine installations until his present promotion.

Changes at Walworth

John M. Olmsted, for many years a vice president in charge of sales on the Pacific Coast for the Walworth Company, manufacturers of valves and pipe fittings, retired on December 31, according to a statement issued by W. B. Holton, Jr., president of the company. "J. M. O.," as Olmsted is familiarly known to his many friends, had his headquarters in Los Angeles and supervised the sales activities of the Walworth Company's West Coast offices, in Seattle, San Francisco and Los Angeles.

Effective on January 1, 1946, Fred J. Chittenden, for 17 years manager of the Walworth Company's San Francisco offices, became manager of West Coast sales, continuing his headquarters in San Francisco.

Appointment

STEWART S. CORT has been appointed manager of the sheet and plate sales division of Bethlehem's Pacific Coast Steel Corporation. Cort, who has been for the past year in the same division of the home office plant in Bethlehem, Pa., is the first manager Bethlehem has appointed to this phase of the steel business on the West Coast. This is an excellent indication that the company looks forward to an extended market in this business in the West.

Accident Prevention Contest for Stevedoring and Terminal Companies

In the Accident Prevention contest of the Waterfront Employers' Association of the Pacific Coast, in which trophies and awards are being offered for safety records established by member organizations, the Pacific Marine Review is the donor for the Columbia River District, onshore group. In all there will be 14 trophies, awarded annually, and 60 certificates. Eighteen donor companies are participating.

The plan of the contest is based on safety statistics for the members in each regional group. The winners of the awards announced for February, 1946, together with the regional group listing, are as follows:

Columbia River District Onshore, winner, Portland Stevedoring Company; Columbia River District Offshore, winner, Portland Stevedoring Company; Columbia River District Terminal, winner, Interstate Terminals, Inc.; San Francisco Bay District Onshore, winner, San Francisco Stevedoring Co.; San Francisco Bay District Offshore, winner, Jones Stevedoring Company; San Francisco Bay District Terminal, winner, Howard Terminals; Southern California District Onshore, winner, Crescent Wharf & Warehouse Co.; Southern California District Offshore, winner, Matson Navigation Company; Puget Sound District Onshore, winner, Alaska Steamship Company; Puget Sound District Offshore, winner, Rothschild-International Stev. Co.; Puget Sound Terminal, winner, Baker Dock Company; Coastwise Onshore, winner, San Francisco Stevedoring Co. (S. F.); Coastwise Offshore, winner, Matson Navigation Co. (L. A.); Coastwise Terminal, winner, Baker Dock Company (Tacoma).

The first award was made February 15 and future awards will follow on about the same date each year until 1949.

Consultant Opens Office

G. Chauncey Parsons, former chief engineer and general manager of Durkee Marine Products Corporation, West Coast Division, is opening his own office in San Pedro, as consultant on general and marine engineering problems. He plans to be available to do some design work on yacht and commercial boats. He is the originator and patentee of the "Parsons Method" of building smooth, small, steel-hulled vessels. At the present time, there are three licensees building boats by this patented method, Central Boat Works and South Coast Company, at Newport Beach, California, and Harbor Steel Fabricators, at San Pedro, California.

Mr. Parsons will also manufacture and market certain marine specialties under the trade name "Parsons Products."

Lessons in Crystal Gazing

With "V-J" Day well past, we have been besieged with the question "When are we going to get Manila rope?" *

If we were expert crystal gazers perhaps we could supply the answer. But our crystal shows only a big question mark where the subject of Manila fiber supply is concerned.

We do know that every day brings nearer the time when you WILL once more have Manila rope and you may be assured that our organization is doing everything to hasten this time. No matter when that time comes, you'll be glad that you waited for the Extra Superior trademark. It is your assurance of a rope made with the FINEST Manila fiber—a rope that stands up under the hardest condition.

Samething to look forward to—this famous rope trademark.

TUBBS
EXTRA SUPERIOR MANILA
CORDAGE COMPANY

* Even though new government regulations permit the making and use of Manila rope (3¾" circ. and larger), fiber supply is far insufficient to fill the demand.

EQUAL emphasis upon all five vital qualities makes Columbian Tape-Marked Pure Manila Rope a *balanced* rope! In a good rope none of these qualities should predominate, for the accenting of one quality is at the cost of the others.

STRENGTH . . . The test for breaking strain alone does not make quality! The minimum point established by the United States Bureau of Standards is one which Columbian Manila Rope has considered a minimum for years. Our standards were so high we had to make no change to meet government requirements. But strength alone is not enough. COLUMBIAN *Balanced* Manila ROPE has equal emphasis on all five!

MARITIME INDUSTRY NEEDS PUBLIC RELATIONS

In this crucial period our industry has many **musts.** Having gone all-out for war as few other industries did, and having been stymied at every approach toward reconversion, it needs to consolidate its thinking and its acting, so that necessarily divergent elements do not conflict at so many points.

Every branch of the industry has a big stake in the welfare of the whole. While we waited for a ship sales bill there could be very little in the way of plans for ship conversion or ship construction or ship operation; and now there is a further wait for the setting of the "pre-war" and "wartime" costs. Some companies have been so situated as to permit of some progress; some have not.

The point is that a strong industry needs to have all its units functioning. A weakness in one unit affects all. A united advance in the entire maritime industry is a **must.**

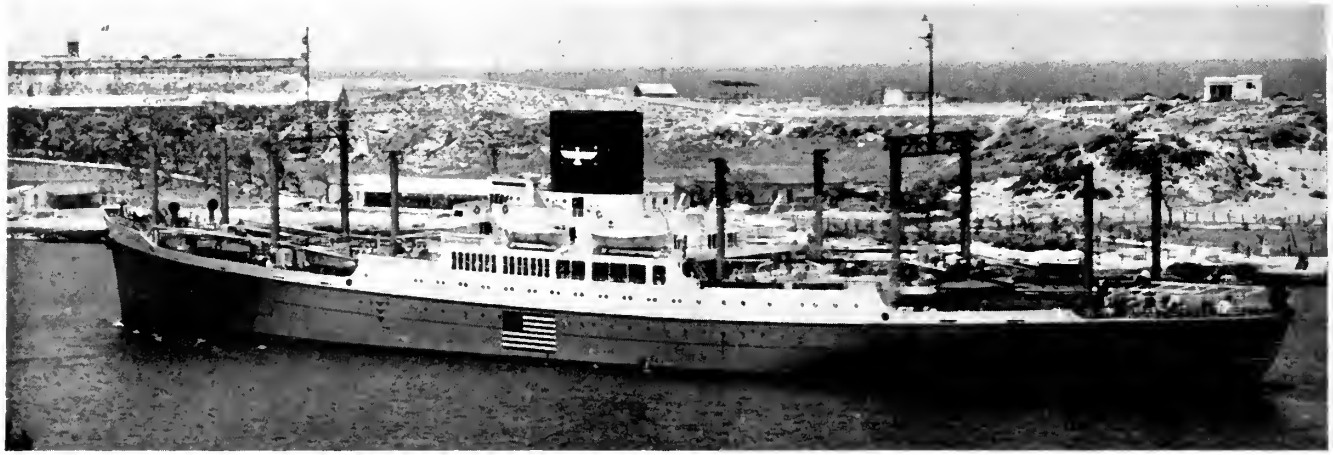
We propose to analyze the various needs of the industry in a series of short articles or editorials. Included will be such subjects as port costs, rail and water rates, air-water combinations, canal tolls, world trade, coastwise and intercoastal difficulties, and others on which there should be a common basis for opinion and action. But first, public relations.

In every human relationship there is some common ground for a mutuality of interest, and that interest can be broadened. Shipping people have—must have—a relationship with the public, with the government, with labor, and with each other. All are interested—vitally interested—in the success of the industry as a whole. But too frequently some spark of irritation or jealousy flames into animosity and the vital objective is lost to view. Or some inadroit spokesman may be regarded as representative of the industry when he is thinking only of his own interests. Or we may stoop to the folly of adopting the expressions of critics, like "subsidy" when we might say "parity payments for labor"; or "embargo foreign trade" when our imports are even more vital than our exports.

We know that we have an industry that is important to the welfare of the country. But in the public mind the industry is something less than vital. Can't we get the story over? In time of hazard, the shipyards and the operating skills of the steamship companies have the admiration of all, but as with the Army and Navy or the Doctor or Policeman, when the danger is overcome they are crowded out of the public mind by more timely problems.

There are many points of peacetime interest between us and the public generally. For instance, what would the 15,000,000 people who are concerned with the cotton industry do if the half of their production which is exported were to be left unshipped? Or the farm and rural communities if the fourth of their crops now exported were to find no market? Or the factories of the country which now need some five billion dollars worth of imports to keep them employing millions of workers? Or even the taxicabs of a city like San Francisco which take $900,000 a year from water front and tourist traffic? We could go on and mention here the dollar interest of almost every element in the population. Let us tell all these people of **their** stake in shipping so their **hearts** will be with us.

The National Federation of American Shipping, the Propeller Clubs, the American Merchant Marine Institute, the local clubs and societies, and the maritime press are earnestly struggling with the public relations problem and are all seeking the same result. The best we can put into the job of helping them is the least we should offer.



The President Polk in Havana Harbor before the war.

S. S. President Polk

First Big Conversion Job on Pacific Liners

Having served as an Army transport through the late war with efficiency and honor the S. S. President Polk is now being restored to her original state as a round-the-world passenger and cargo liner for the American President lines. This job, after competitive bidding, was awarded to a Pacific Coast shipyard. It is expected that a sister ship the President Monroe will be similarly restored in the near future.

After the reconversion work is finished these vessels will appear within and without substantially as shown in the illustrations herewith. They are C-3's fitted with first-class passenger accommodations for 97 persons and will be used in the trans-pacific service.

These vessels have very sea-kindly hulls with a large cubic and dead-weight capacity for cargo and are equipped with every modern fitting and device to maintain comfortable conditions in the staterooms and public rooms for the passengers and to insure an abundance of wholesome and delicious food in the dining saloon.

Principal characteristics of the ship are shown in the line box herewith. It will be noted that these vessels have a good turn of speed and ample oil tankage capacity for great cruising radius. The space amidships occupied by the propulsion machinery is very short leaving ample opportunity fore and aft for large cargo holds.

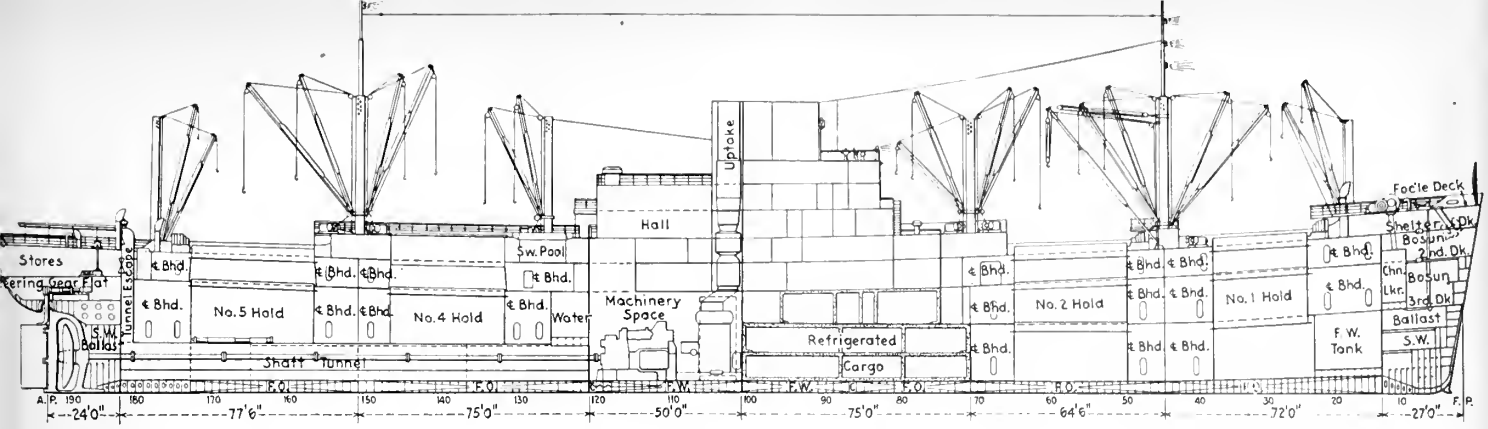
As originally built she was delivered late in 1941 to the American President Lines by the Newport News Shipbuilding and Dry Dock Company.

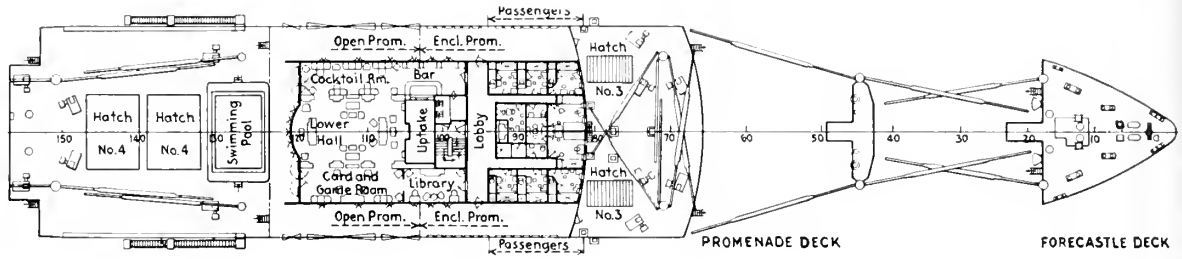
Propulsion Machinery

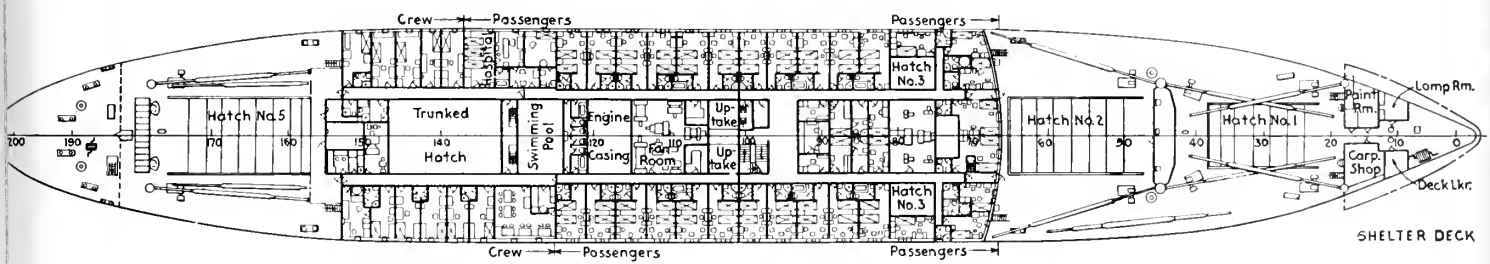
Propulsion machinery is of the steam turbine geared transmission type using steam at 440 psi and 740° F. total pressure and rated 8500 shp with 28½ inches vacuum on the condenser and with the propeller turning 85 rpm. Two sectional header type Babcock and Wilcox marine water tube boilers, designed for a pressure of 500 psi are installed, each of which supplies 37,500 lbs. per hour of 450 psi steam at 750° F. Each boiler is capable of 50 per cent evaporative overload. Each boiler is fitted with 5 B and W wide range type oil burners served by Quimby screw type pumps and by Griscom-Russell oil heaters. Oil is delivered to the burners at 300 psi and 230° F. Two Sturtevant force draft blowers driven by Westinghouse motors deliver air to the burners through the air pre-heater and the space between the inner and outer boiler casings. Bailey automatic combustion control takes care of the fuel-air ratio and the feed water adjustment. Diamond soot blowers keep the heating surfaces of the boilers clean. A Hays Corporation flue-gas analysis outfit checks combustion and a Hancock injector introduces make-up feed.

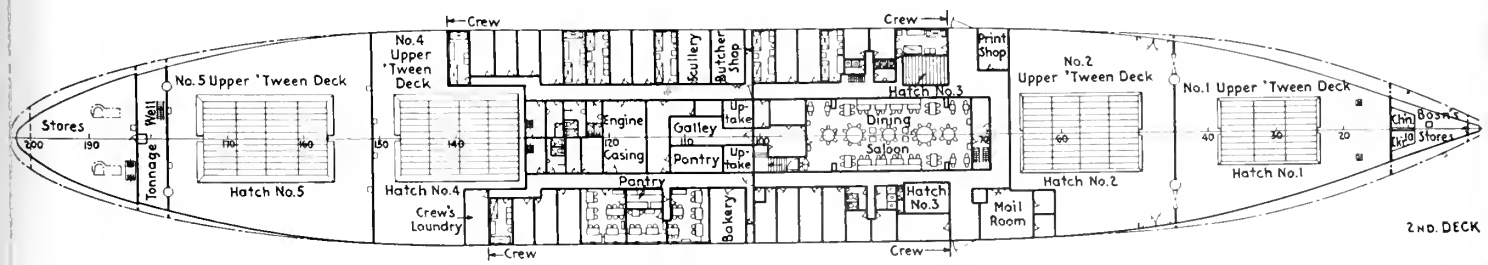
These boilers are mounted just forward of and in the same compartment with the main turbine—and a very short main steam pipe connects the boiler drum outlets with the turbine throttle. The entire propulsion machinery occupies only 50 feet in length in the mid-body of the ship for 8500 shp with 25 per cent overload capacity and for all auxiliaries with no crowding.

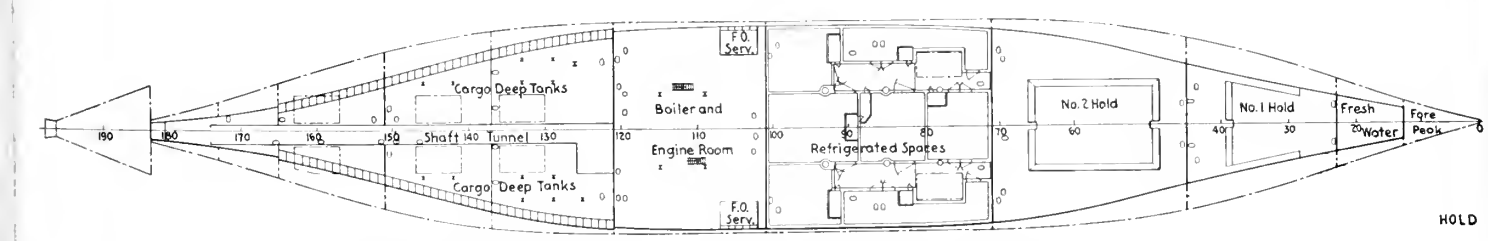
Newport News designed and built the turbines of their own impulse-reaction type. The turbine is of the











INBOARD PROFILE AND GENERAL ARRANGEMENT PLANS OF THE PRESIDENT POLK

Pacific Marine Review, April, 1946

cross compound type with high pressure rotor running 4504 rpm and low pressure rotor at 2289 rpm and with the shafts of the rotors connected through flexible pinions to the shafts of the high speed pinions of a Westinghouse double reduction gear set which drives the propeller line shafting at 85 rpm through a six shoe segmented type Howarth Pivoted thrust bearing.

The turbine water rate does not exceed 6.97 lbs. shp and the combined fuel consumption does not exceed 0.6 lbs. shp. Mounted on top of a Newport News two pass type condenser the low pressure turbine unit exhausts directly into 7800 sq. ft. of cooling tube surface in a space served by a C. H. Wheeler twin two stage type air ejector with inter and after and gland leak-off condensers which maintain a vacuum of 28½ inches when served with 250 psi steam. Cooling water is circulated by a De Laval horizontal centrifugal pump, of 13,000 gpm capacity at 10 psi, driven by a 100 hp Westinghouse motor.

From the hot well at the bottom of the condenser the condensate follows the now standard American path back to the boiler. Two Worthington vertical centrifugal pumps, with a capacity for 140 gpm at 180 feet head and driven by a 15 hp Westinghouse motor, discharge the condensate through the inter and after and gland leak-off condensers of the air ejector; the Davis drain cooler; the first stage Davis feed water heater, and to the Cochrane deaerating heater. This latter heater is located at shelter deck level 36 feet above engine room floor and provides a positive suction head for the feed pumps. Feed pumps are in duplicate —Warren horizontal centrifugals driven by Terry turbines—and taking suction from the deaerating heater deliver hot feed water through the Davis third stage heater to the boilers. The feed heaters are served by bled steam from the turbines—first stage at 7.1 psi deaerating, second stage at 25 psi, and third stage at 100 psi, all absolute. Feed goes into boilers at approximbately 318° F.

The propeller is a right-hand four blade solid cast Cramp brass manganese bronze wheel with a diameter of 21 feet 8 inches. It weighs 21 tons and has an expanding pitch measure of 21 feet 8 inches at 0.7 of the radius. At normal horsepower in calm seas this plant drives the hull easily at 18 knots. At 19.5 knots there is no sense of vibration on deck and no machinery noise. Three De Laval Westinghouse geared turbo-electric generators each of 300 k. w. capacity furnish electric energy for the auxiliary power, cooking, and lighting loads. The total connected electric load for these three classes approximates 2500 hp. Carrier refrigerating and air conditioning units take care of the refer cargo ship's stores, and complete temperature and humidity control for the dining room and certain other compartments.

Principal Dimensions

Length over-all	492 feet
Length between perpendiculars	465 feet
Beam, molded	69 feet 6 inches
Draft, full load, molded	26 feet 6 inches
Depth, molded to shelter deck	42 feet 6 inches
Shaft horsepower	8500
Speed	16½ knots
Gross tonnage	8500 tons
Deadweight tonnage	9400 tons
Fuel capacity	1455 tons
Displacement	16,190 tons
Bale capacity	568,050 cubic feet
Passengers	97
Crew	135

Passenger Accommodations

The work now in progress will be largely concerned with restoration of the public spaces on this vessel. These comprise sleeping, dining, and recreational facilities for 96 passengers. Sleeping accommodations are: six single and two three-person rooms on promenade deck; and six rooms for two persons, and twenty-four rooms for three persons on the shelter deck. All three-person rooms have two single beds and a pullman berth. All rooms have private toilet and lavatory and a tub or shower bath. All furnishings and fittings are up to first-class hotel standards.

The public rooms on the promenade deck are closely grouped and amply spacious for the passenger complement. They are surrounded by a fine broad promenade deck which is enclosed with Kearfott Full-vu windows. At the after end of the group of public rooms is a sports deck and built-in open swimming pool. Immediately forward of this area is the main lounge two decks high and finished at its after end with full height windows shielded by Venetian blinds. These windows afford an interesting view of the sports deck and pool and beautiful vistas of the sea.

Forward of this lounge are: a card room; a veranda cafe and bar; a library and writing room; and a lobby with gift shop and other conveniences. All of these rooms are decorated in a simple modern motif. Architecturally they stress the functional. All ventilating ducts are carefully worked into a harmonious scheme of line and color treatment. Furniture upholstering, deck coverings and drapes blend beautifully with each other and with the motif so that the impression is smart comfort.

Ventilation, air conditioning, and sanitary arrangements on these ships functioned more perfectly than on most of the large passenger liners on which we have traveled.

The dining room on the second deck depends entirely on electric light and mechanical ventilation and air conditioning. It is a rather narrow room. The interior decorators have so skillfully treated this unpromising interior that a diner has almost a perfect illusion of eating in the open air under tropic foliage. Air conditioning of this room and the pantries and galley adjoining is so perfect that there is a complete absence of objectionable cooking and food odors.

If the reconversion program succeeds in restoring completely the charm and comfort of these passenger accommodations we will soon have again running out of the Golden Gate a pair of transpacific passenger and cargo liners, equal in every comfort to any vessels on such service under any flag.

Merchant Ship Sales Act of 1946

By A. J. Dickie

The long eagerly-awaited Ship Sales Bill has now passed through the Congressional mill, has been signed by the President and so has become a law substantially as follows:

Section I—Name

The name of this act shall be Merchant Ship Sales Act of 1946.

Section II—Policy

(a) This measure declares its policy to be the maintenance of "an efficient and adequate American-owned merchant marine": (1) sufficient to carry American domestic waterborne commerce and a substantial portion of American export and import foreign commerce and to provide American shipping service on all essential trade routes for such commerce (2) capable of serving as a naval and military auxiliary in time of national emergency (3) owned and operated under the American flag by citizens of the United States; (4) composed of the best equipped, safest and most suitable types of vessels, built in the United States, and manned with a trained and efficient citizen personnel; and supplemented by efficient citizen-owned facilities for shipbuilding and ship repair, marine insurance and other auxiliary services.

Section III—Definitions

(a) **Commission** means the U. S. Maritime Commission.

(b) **War-built vessel** is defined as an ocean-going vessel of 1500 gross tons or more, owned by the United States, suitable for commercial use, which (1) was constructed or contracted for by or for the account of the United States from January, 1941, to September 2, 1945; or (2) was constructed from September 3, 1939, to September 2, 1945, and was acquired by the United States during that period.

(c) **Pre-war domestic cost** (p.d.c.) is the amount determined by the Commission (and published in the Federal Register) to be the cost of such a vessel built in the United States under conditions obtaining on or about January, 1, 1941, and in no case greater than 80 per cent of the domestic war cost of vessels of the same type.

(d) **Statutory Sales Price** (s.s.p.) is 50 per cent of pre-war domestic cost for freighters, 87½ per cent of p.d.c. for tankers, in each case subject to following adjustments:

(1) Cost of putting vessel in class to be subtracted;

(2) Cost of adding desirable standard vessel features to be subtracted;

(3) Cost of desirable features not in standard vessel to be added;

(4) Depreciation at 5 per cent per annum from date of original delivery to date of sale plus an additional 3 per cent per annum on cargo vessels or 4 per cent per annum on tankers for periods of war service.

In no case shall these adjustments reduce the s.s.p. below 35 per cent domestic war cost for standard cargo vessels, 31.5 per cent d.w.c. for Liberty type vessels, or 50 per cent d.w.c. for tankers.

(e) **Domestic War Cost** (d.w.c.) means the average war cost of the type taken without national defense features during the six months' war construction period most representative for that type.

Section IV—Sales to Citizens

(a) Any citizen may make application to purchase any war-built vessel under jurisdiction of the Commission and the Commission must sell if it finds that the applicant has the "ability, experience, and financial resources" necessary to "operate and maintain the vessel."

(b) At time of sale citizen must pay 25 per cent of s.s.p., paying the balance in not more than 20 annual installments at 3½ per cent interest per annum.

Section V—Charter to Citizens

(a) Any citizen may apply to the Commission to charter "a war-built dry cargo vessel for bareboat use." The Commission shall not approve unless in its judgment such charter would be consistent with the policies of this act, and no charter shall be made until 60 days after publication of the applicable p.d.c. in the Federal Register.

(b) Charter hire shall be fixed by the Commission and shall not be less than 15 per cent of the statutory price per annum except on an affirmative vote of at least 4 Commissioners.

(c) The provisions of Sections 708, 709, 710, 712 and 713, of the Merchant Marine Act of 1936, as amended, shall be applicable to all charters made under this section.

Section VI—Sale to Non-Citizens

(a) Commission is authorized to sell vessels to non-citizen applicants with following restrictions:

(1) Applicant must have necessary ability, experience and financial resources and sale must be consistent with policies of this act and with Section 9 of Shipping Act of 1916;

(2) Vessel must be unnecessary to defense of United States;

(3) Vessel must be unessential to the American Merchant Marine; and

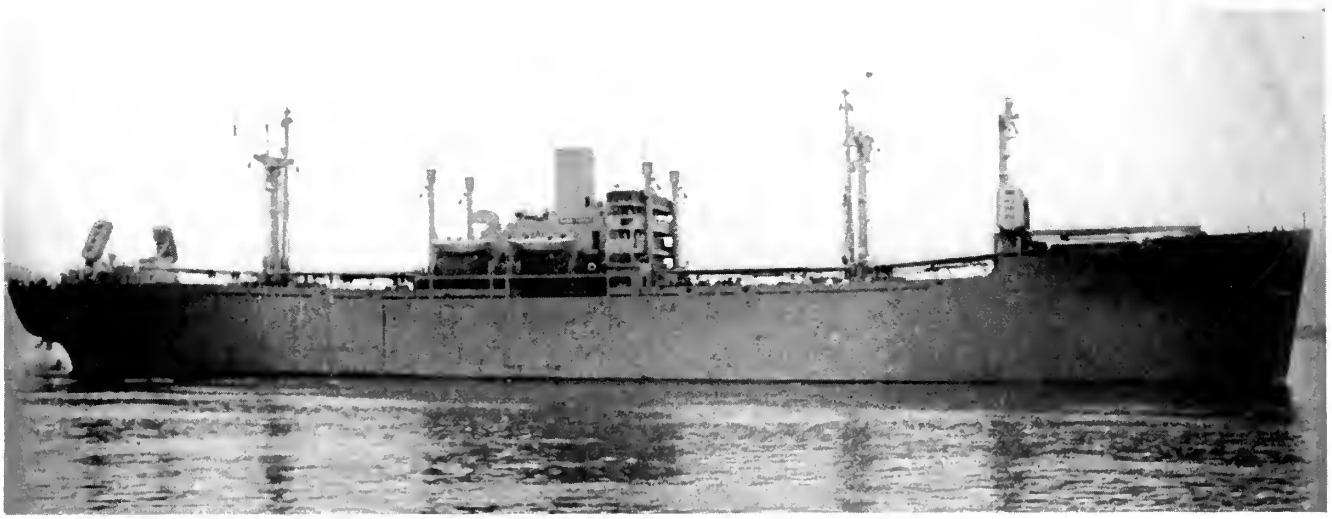
(4) Sales must not be made until a reasonable period of time after publication of p.d.c. in Federal Register—this period for "C" type vessels and tankers to be not less than 90 days—the vessel for such period having been available for sale or charter to citizens.

(b) The preferred mortgage securing the balance of unpaid price in cases where vessel is being transferred to foreign register shall contain clauses insuring it as preferred over any other liens or encumbrances under the laws of such registry.

Section VII—Order of Preference

(a) The Commission shall give preference to: citizen applicants over non-citizen applicants; citizen applicants to purchase over citizen applicants to charter and citizens of the Philippines over other non-citizen applicants. In each case the Commission shall consider the war loss in tonnage of the applicant and shall give preference to former owners of the vessel.

(b) After cessation of hostilities,



The Victory type. Estimated statutory sales price $917,979.50. Charter rate per annum $137,696.93. Charter rate per month $11,474.00.

operation of commercial vessels by the United States either for its own account or through operating agents shall, except as to services specifically authorized by law, be continued "only to the extent necessary to effect orderly transfer of vessels to private operation."

Section VIII Exchange of Vessels

Authorizes the Commission to acquire vessels in exchange for an allowance of credit on the sales of its own vessels or of any vessels built in the United States after January 1, 1937, and acquired by exchange. Many restrictive clauses qualify this authorization. Principal of these are as follows:

The vessels to be exchanged: must be one owned by a citizen and not acquired by purchase under this act; or must be one built in the United States and owned by a foreign corporation, controlling interest in which is owned by a United States citizen, and which agrees to operate purchased vessel; and shall be documented in the United States.

The trade-in allowance: shall not be applied on the cash payment required; shall be the fair and reasonable value of the vessel as determined by the standards of Executive Order 9387 (8-F.R. 14105) as of the date of offer; shall not be greater than one-third of the s.s.p. (unadjusted) of the vessel to be purchased, or the liability of the United States under charter for restorations of such vessel, whichever is higher; and, on vessels acquired from the United States, shall not be greater than price paid for the vessel plus depreciated value of subsequent improvements.

The application for such a trade-in must be in the nature of a firm offer binding for 90 days.

Section IX—Adjustment of Prior Sales

Any citizen of the United States who: owns a vessel acquired from the Commission prior to the enactment of this act and delivered by its builder after December 31, 1940; is party to a contract with Commission to purchase a vessel not yet delivered; or owns or has contracted for the construction of a vessel on which a construction differential subsidy was paid or agreed to be paid; shall be entitled to an adjustment in the price of such a vessel by treating the vessel as if it were being sold to the applicant on the date of the enactment of this act.

This adjustment is qualified by subadjustments of mortgage payments, interest payments, Federal tax payments and agreements to limit charter hire and liability of the United States on vessels operated by U. S. under charter.

Section X Limitation of Eligibility

No person is eligible to purchase or charter or receive adjustment on sales price without entering with the Commission into a binding agreement that the liability of United States for any vessel, owned by the applicant and under charter to the United States, shall be limited to "just compensation" as of the date of loss.

Section XI—Reserve Fleet

Directs Commission to place in National Defense Reserve such vessels as: Commission, Secretary of War, and Secretary of Navy jointly shall deem necessary; and all vessels owned by the Commission after December 31, 1947, for the sale of which no contract has been made up to that time except those deemed of insufficient value for commercial and defense purposes.

Vessels placed in reserve shall not be used for commercial purposes except during periods of emergency under Section 902 of Merchant Marine Act of 1936 as amended. Any war-built vessel may be made available to any State maintaining a marine school according to Act of July 29, 1941 (Public Law 191, Seventy-Seventh Congress 55 Stat. 607).

Section XII—General Provisions

(a) Authorizes Commission to reconvert or restore any vessel authorized to be sold or chartered.

(b) Exempts contracts of the Commission from provisions of Section 202 of the War Mobilization and Reconversion Act of 1944.

(c) Permits vessels sold to citizens under this Act to engage in Coastwise Trades of the United States even though they had been engaged in foreign flag service during World War II.

(d) Impounds all moneys (received by Commission under this

Act) in the Treasury under Miscellaneous receipts. Specifically applies to the provisions of this Act all the provisions of Sections 201 (d), 204 (b), 207, 209 (a), and 905 (c) of the Merchant Marine Act of 1936 as amended.

Section XIII—Reports

Commission on July 1, 1946, and every three months thereafter must make reports to Congress on all activities and transactions under this Act.

Comment

This Act is somewhat complicated. An apparently sincere effort to help establish a privately owned American Merchant Marine by selling the war built tonnage to American citizens at very reasonable prices has bogged down into a mass of "complex and cumbersome" rules in regard to fixing prices and charter hire.

Pre-war domestic cost of building a similar ship is the basis of price computation. This, however, is qualified by an artificial floor. This cost cannot be less than 80 per cent of the domestic war cost of a similar ship. However, the pre-war domestic cost as thus established will be used as the base.

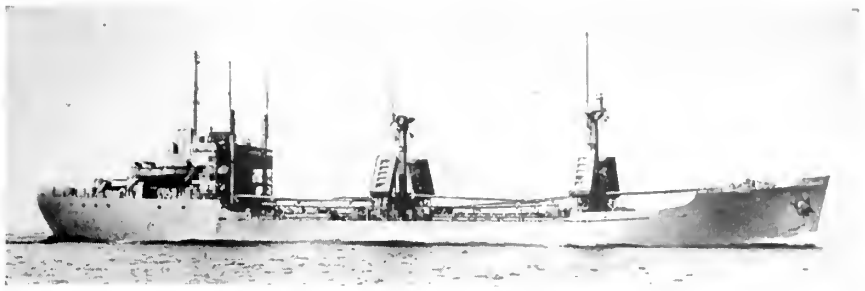
Next we have a Statutory Sales Price which is 87.5 per cent of p.d.c. for tankers and 50 per cent of p.d.c. for cargo carriers. This s.s.p. can be further reduced by depreciation, expense for putting in class, and expense for adding desirable standard equipment originally but not now in the vessel. However, this reduction process can go no lower than a fixed percentage of the domestic war cost—31½ per cent for Liberty ships; 35 per cent for standard cargo types; and 50 per cent for tankers.

Such criteria for basic prices require a survey of each vessel before an accurate selling price for that vessel can be established. This means long delays and on top of these delays there is imposed a 60-day wait after publication of the price before the vessel can be chartered and a 90-day wait before the vessel can be sold to a non-citizen buyer. These delays may make it impossible to take advantage of a very good ship sales market.

A rough idea of the statutory sales prices is given by the table herewith which sets forth the estimate of the War Shipping Administration establishing interim charter hire rates for the various types.

Section 709, Merchant Marine Act 1936 provides that if any charter operator makes in the operation of a vessel more than 10 per cent net per annum on his invested capital one-half of the excess over 10 per cent net shall be paid to the Commission as additional Charter hire. Definitions of the terms "net voyage profit," "fair and reasonable overhead expenses," and "capital necessarily employed" are in the charter form together with formulae for determining the quantities involved.

As we read this Act of 1946 we are impressed with the tremendous effort that is made to prevent any loss to the United States through irregularities in such sales as may be made. We still believe that if Congress had in 1945 accepted from the Navy and the Maritime Commission the schedule of the ships thought to be essential for future emergencies and had then authorized the Commission to sell the balance of the fleet on the world's markets at world market prices we would by this time have sold a few hundred vessels and would have plenty of all types left to furnish a more than adequate American privately owned merchant marine in addition to the laid-up fleet. We would by that method have sold on a higher market, have realized a better price, and have had far less selling cost than will be entailed by sales under the present Ship Sales Act of 1946.



C1-M type. Estimated statutory sales price $640,000. Charter rate per annum $96,000. Charter rate per month $8,000.

Type Vessel	Deadweight Tonnage	Estimated Statutory Sales Price (Mean)	Charter Rate Per Annum 15% of Sales Price*	Charter Rate Per Month*

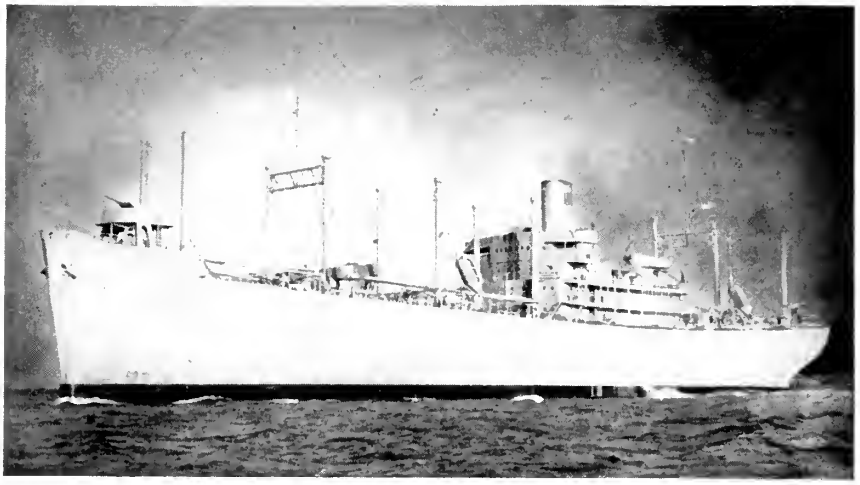
Policy Governing Interim Chartering of Ships by War Shipping Administration

I. General Statement of Purpose And Intention

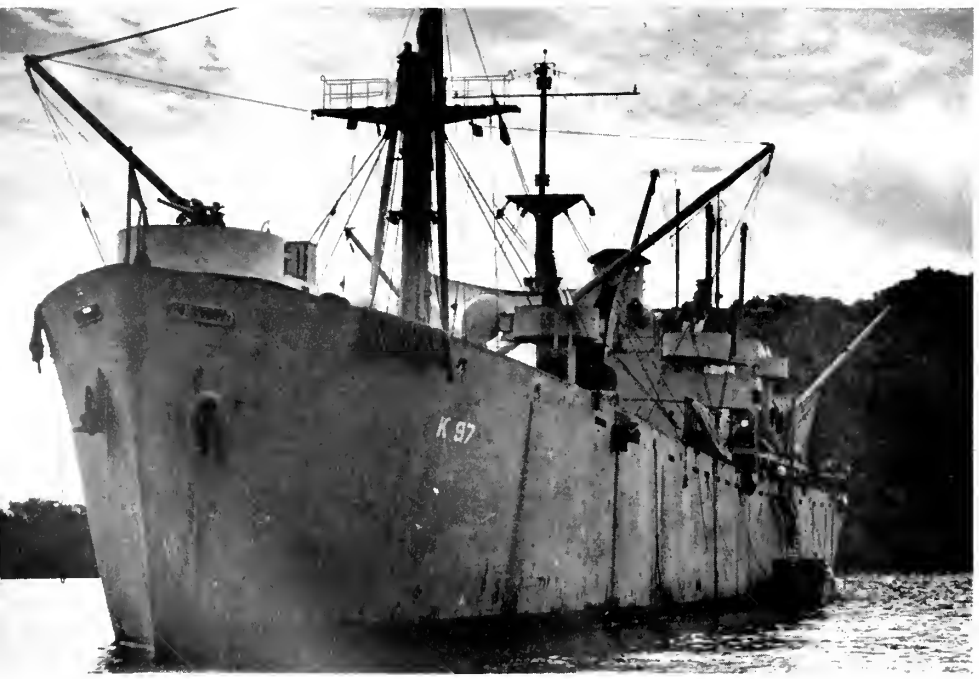
With the termination of the UMA agreement on March 2, 1946, the WSA proposes to derequisition vessels chartered to the WSA as rapidly as possible so as to achieve prompt resumption of private shipping by operators owning their own vessels. It is obvious that the tonnage requirement necessary for transportation of foreign commerce of the United States will far exceed the privately owned tonnage to be derequisitioned The UNRRA requirements and national import programs will create an emergent demand for tonnage during at least the calendar year 1946 and well into 1947. During this period it is felt necessary to curtail WSA operation through agents to the greatest extent possible, in order that dual operation (government and private) with its attendant disadvantages may be avoided.

The policy of the Ship Sales Bill is to encourage the ownership and operation of the merchant fleet of the United States by citizens thereof and the retirement of the Government from ship operation through the sale or charter of war-built tonnage. The pending bill provides that no charters shall be made under the Act until sixty days after the publication by the Maritime Commission of the statutory sales prices. However, as the Report of the Joint Conferees states: "The bill would not affect the existing authority of the War Shipping Administration and the Maritime Commission to charter vessels to citizens of the United States, which may be necessary for limited periods to speed up the resumption of private steamship operation." It is proposed, therefore, that with the termination of UMA, WSA will undertake a program of interim bareboat chartering under the authority of P.L. 101, 77th Congress, authorizing the charter of vessels "necessary for transportation of foreign commerce of the United States or of commodities essential to the national defense, upon such terms and conditions, for such period or periods, and subject to such restrictions as the commission (now WSA) may deem necessary or desirable for the protection of the public interest, and at such rate of hire as it may deem to be fair and reasonable." It is intended that this program shall remain in effect only for such period as may be required for the chartering provisions of the Ship Sales to become fully operative. The provisions of the interim charters therefore will be patterned generally after the provisions of the Ship Sales Bill.



C3 type. Estimated statutory sales price $1,154,000. Charter rate per annum $173,100. Charter rate per month $14,425.

The Liberty type. Special conditions apply to Libertys.



Following the termination of the UMA agreement on March 2, 1946, the War Shipping Administration will undertake to assure that adequate U. S. flag tonnage is available to transport this nation's fair share of its foreign commerce. It will also contribute tonnage to a pool to be formed for the common task of relief and rehabilitation including the shipping requirements of UNRRA for cargo moving from the United States and Canada. These requirements will be centrally programmed in Washington and so far as possible cargo to move on United States flag ships will be allocated to privately owned or chartered shipping. Any deficiencies resulting will be met by government owned tonnage.

The WSA does not expect to exercise any direct control over privately owned tonnage except to see that it is employed in a manner not inconsistent with the overall programs and the welfare of the Ameri-

can Merchant Marine in general. The cost of moving cargoes for relief and rehabilitation will however continue to be of direct concern to this Government and freight rates for such cargoes therefore must conform with Conference or WSA approved rates. At the same time WSA recognizes fully that participation by private capital is dependent upon adequate and compensatory rates.

The WSA hopes that a large share of this Government's obligation for the transportation of relief and rehabilitation cargoes will be met by privately owned or chartered tonnage.

II. Basic Policy Regarding Chartering

Charters will be made to:

(a) Operators of liner or berth services who will be expected to bring their fleets up to the standards required for peacetime operation pending acquisition of new tonnage and/or redelivery of their owned vessels.

(b) Liner or berth operators to provide additional tonnage necessitated as a result of the war or in the relief and rehabilitation program, to handle the additional cargo moving on berth vessels.

(c) Experienced operators other than those engaged in berth services for the transportation of commodities which move under contract and in full-cargo lots.

(d) Other operators who qualify and commit themselves to purchase ships under the Merchant Ship Sales Act of 1946.

(e) Operators for employment in cross trades (that is between foreign ports where such operation is in the interest of the over-all Government program and does not conflict with a United States flag berth service.

III. Form of Charter

A draft of proposed "WARSHIP-DEMISEOUT" as an interim charter, the provisions of which are patterned generally after those of the Ship Sales Act, has already been released. Comment on the provisions of this charter is unnecessary for the purpose of this statement, except to state that the trading limits will be in conformity with the basic policy set out in paragraph "II" herein and that WSA must exercise reasonable control over the routing and cargo carried by the ships it charters.

The preceding table sets forth proposed basic charter rates for standard vessels based on the pending Ship Sales Bill.

IV. General

In the allocation of cargo to be carried by U. S. flag vessels, first preference will be given by WSA to the owners and second preference to charterers of the U. S. flag vessels.

Except in very unusual cases, no charters will be made under the authority of P.L. 101 (77th Congress) after the effective date for chartering under the Ship Sales Act. Furthermore, it is intended that these interim charters shall be supplanted by Ship Sales Act charters at the earliest practicable date.

Development of Small-Boat Harbors

A series of small harbors all along California's coastline, providing anchorage for light-draft vessels, long has been a dream of California fishing fleets, yachtsmen and power boat enthusiasts. Now the project has begun to "jell" through start of an organized campaign to make the dream a reality.

Yachtsmen, fishermen and power boat owners have started the ball rolling at a series of meetings already held, and being scheduled. The small craft owners have requested the California State Chamber of Commerce to coordinate this campaign, and sparkplug the initiation of necessary Federal legislation for surveys and appropriations.

Already, the State Chamber, through its natural resources committee, its travel and recreation committee, and its North Coast, Central Coast and Southern California councils, has swung into action. All sections of the California coastline were represented at a big meeting in Newport Harbor, arranged by the State Chamber—and steps for new small harbor projects are under way in Sonoma and San Luis Obispo counties.

Frank M. Shay, San Jose, chairman of the State Chamber's Central Coast Council, has written California congressmen requesting introduction of legislation authorizing an Army Engineer's study of harbors for light-draft vessels in Northern California, similar to existing authority in Southern California.

"Use of these light-draft vessel harbors would serve two principal purposes," Shay points out. "They would provide refuge and landing facilities for the commercial fishing industry. Also, they would provide for recreation. Commercial fishing fleets landed a billion and a quarter pounds of fish in California ports last year. More anchorage and refuges would result in increased catches. Such harbors could also be used by small craft owners for recreational purposes."

Authorization for Army Engineer survey of the Northern California coastline is asked because a similar survey already has been authorized for Southern California. Study is now being made by the Southern California district, U. S. Engineers. This study extends from south of Point Pinos, Monterey County, to the Mexican line.

The Newport Harbor meeting showed small craft owners what can be done in light-draft harbor development. Two northern counties already are doing something about it.

San Luis Obispo County's chambers of commerce, supervisors, planning engineers, commercial fishermen, public representatives and others are working on formation of a San Luis Obispo County harbor district for development of Morro Bay, with freeway and altered streets to give maximum accessibility. The plan contemplates seeking some of the state-held beach park acreage for the development.

Sonoma County's Board of Supervisors was represented at the Newport Harbor meeting. Immediately afterward, the supervisors voted to start proceedings for county acquisition of private acreage on the west shore of Bodega Bay for harbor and recreational uses.

Harbors that can be fitted into the program include Crescent City Harbor, Humboldt Harbor, Noyo, Albion, Point Arena, Bodega Bay, Richardson's Bay, Petaluma River, Napa River, Tomales Bay, Bolinas, Richmond, Martinez, Oakland Outer Harbor, Half Moon Bay, Santa Cruz, Moss Landing, Monterey, Big Sur, Morro Bay, Avila, Goleta, Santa Barbara, Ventura, Oxnard, Port Hueneme, Santa Monica Harbor, Playa del Rey, Redondo, Arroyo de la Cruz, Cambria Pines and Mission Bay.

Re-establishment of International Ice Patrol In North Atlantic Ocean

Admiral J. F. Farley, Commandant of the United States Coast Guard, has just announced the re-establishment of the International Ice Patrol in the North Atlantic Ocean. The President had previously directed that the Coast Guard resume the conduct of the international service of ice observation and ice patrol as the need of protection against icebergs became paramount with the end of hostilities and the resumption of peacetime commercial traffic over the North Atlantic steamship lanes.

The International Ice Patrol was terminated on December 22, 1941, by reason of war conditions and disruption of normal maritime commerce, but a careful estimate of North Atlantic ice conditions was maintained throughout the war. Information concerning the northern areas invaded by pack ice and icebergs was vital for the regulation of patrol craft and the routing of war ships and convoys. The ice conditions in Denmark Strait, for example, directly affected the movement of enemy submarines and surface raiders. This isolated passage between Iceland and

NO FUZZY LAMBSKIN

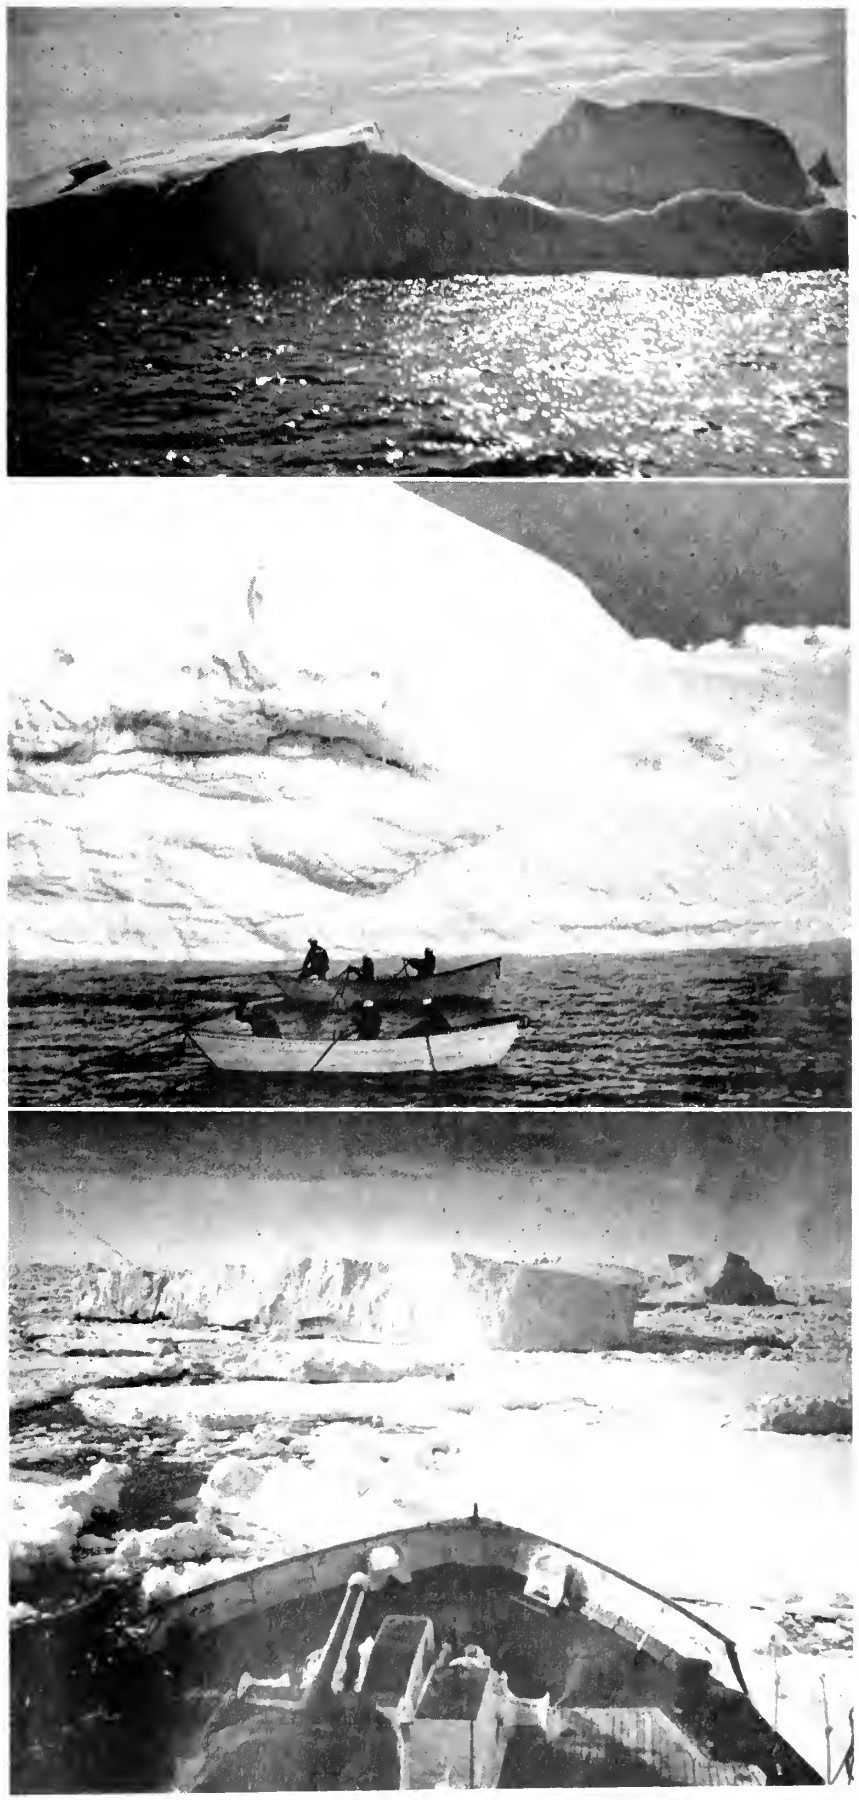
The fuzzy, fleecy look of this berg is strictly a floating wolf in sheep's clothing. Spring brings down whole packs of these bergs, seemingly intent on destruction of helpless merchant vessels, but the U. S. Coast Guard has the answer. Now equipped with radar and Loran, ships and planes of the Coast Guard's international ice patrol locate such floating menaces and radia their position and direction of drift twice daily to shore stations and merchant shipping. This patrol took up its war-suspended duties by presidential order this March.

Greenland possessed too many hazards in the form of field ice and icebergs for ordinary shipping, so became a frequent avenue for German ships entering or leaving the North Atlantic. The presence of pack ice and bergs prevented any general practical mine blockade. It was in the Denmark Strait that the German battleship Bismarck sank the British battleship Hood and later suffered a similar fate in an attempted escape towards Europe.

The iceberg menace is one of nature's elements which man in all his ingenuity and resourcefulness cannot control, regulate or entirely avoid. Breaking off from the massive Greenland glaciers, these icebergs, frequently as long as a block and a half as high, above the water, are carried along by the ocean currents. Some of them reach the Labrador current, and then they start their march toward the heavily-traveled North Atlantic steamship lanes. It is beyond human power to hold them back, to destroy them, or to divert them from their course.

The Coast Guard will inaugurate the ice patrol about March, when the presence of ice generally commences to threaten steamship traffic, in the North Atlantic. The patrol area covers a region of about the size of the State of Pennsylvania, in the general region of the Grand Banks of Newfoundland. During the ice season, which usually extends from April to July, this region is blanketed in fog during a large part of the time, accentuated by the confluence of the Gulf Stream and Labrador current. And through it passes the world's heaviest traffic.

Aviation, Radar, and Loran will be employed for the first time to insure greater certainty of detection and location. Radar and Loran, however,



Top: BEAUTY PACKED IN ICE. Smashing destruction wears a translucent white mask, but mariners know the menacing truth, so Coast Guardsmen man planes and ships equipped with radar and Loran, and cruise into the icy North Atlantic. Foreknowledge of the location and drift of such glacial offspring is obtained by the Coast Guard in its annual springtime ice patrol, which has been resumed by presidential order this year.

Center: A RACE WITH DEATH. Coast Guardsmen on the international ice patrol take to their "keels" in a race with death and time. Experiments in the use of explosives to destroy icebergs have proved the impossibility of such destruction, however, so radio-location and warning are the means adopted by Coast Guard planes and cutters for efficient protection of North Atlantic shipping.

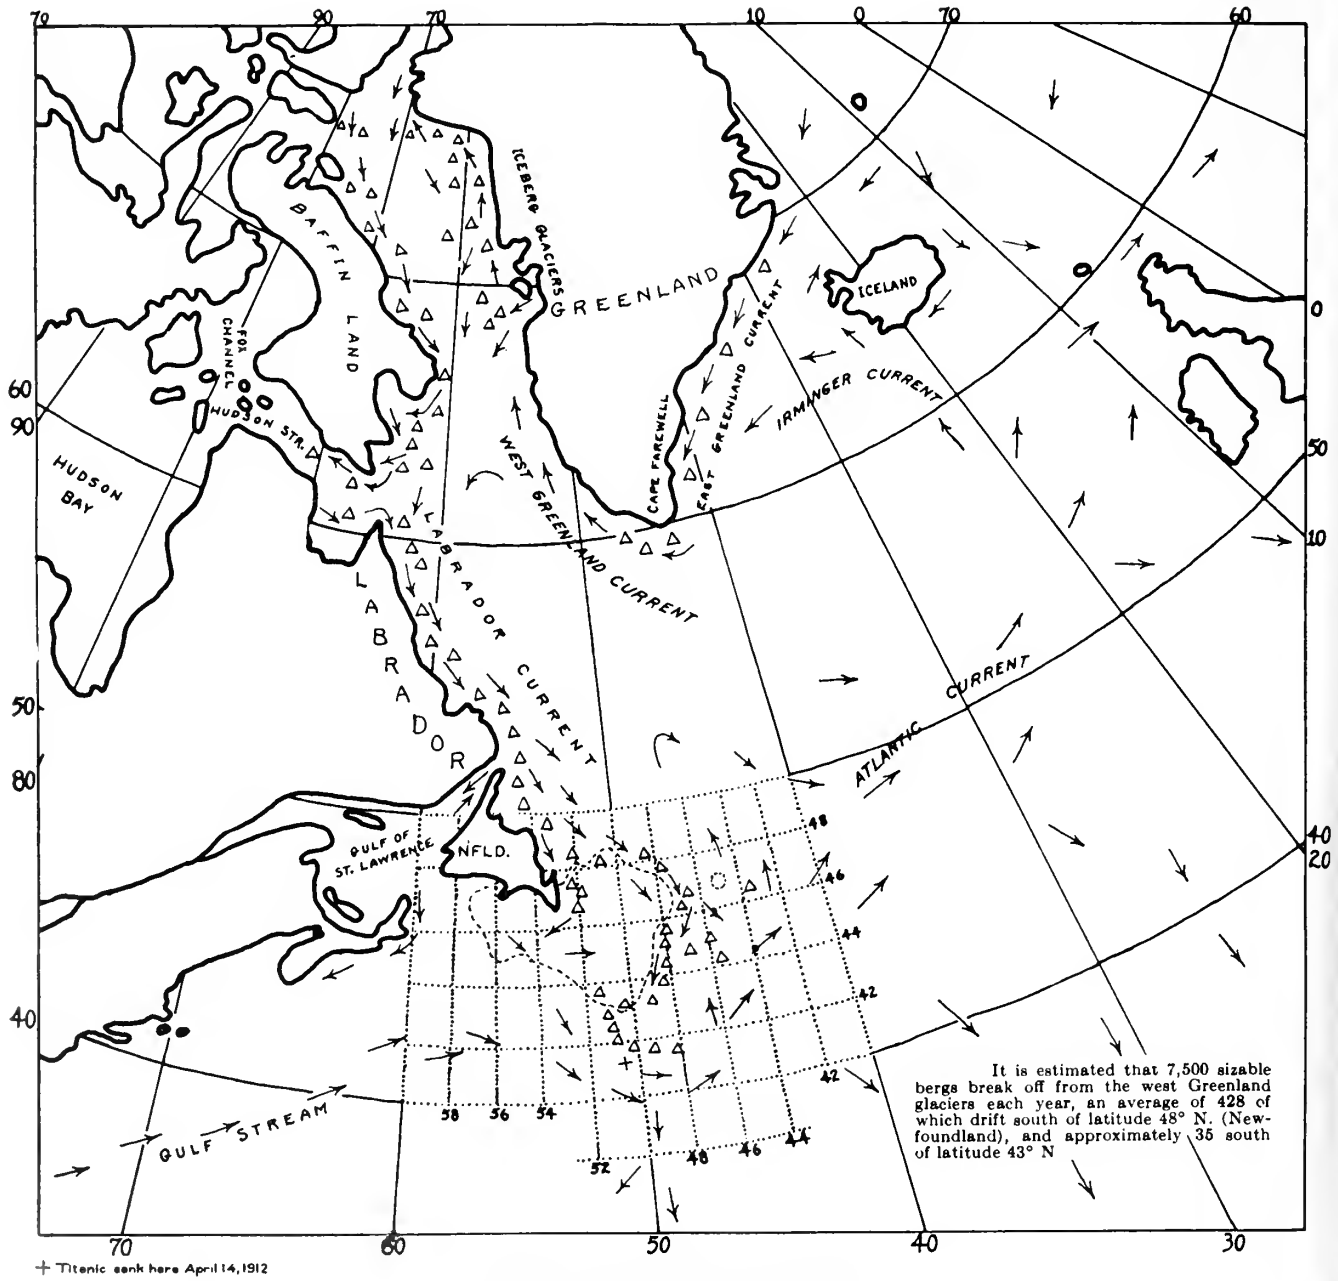
Bottom: SPRING PLOWING. Something new in spring plowing takes place as this Coast Guard cutter heads into the crust of a North Atlantic ice pack. The spring thaw breaks such floating fields off from far northern glaciers; they drift into North Atlantic shipping lanes; and the Coast Guard cutters and planes go out again to begin their vigilant annual patrol, suspended during the war.

are supplemental and are not a conclusive answer for ice surveys. A vigilant patrol will therefore be necessary by cutters and aircraft. Planes and ships will be based at Argentia, Newfoundland, where the International Ice Patrol Commander and staff will make its headquarters.

Coast Guard-manned B-24's will make the aerial surveys, supplemented by additional Coast Guard aircraft when required. The Owasco* class cutters have been assigned for surface patrol. These vessels are especially designed for Coast Guard duty and service conditions, such as rescue at sea, ice breaking, weather patrols and rough weather duties have determined the scantlings and arrangement of structure as well as the mechanical and electrical requirements and equipment. This class of vessel is single screw, turbine-electric, capable of developing 4000 shp. These vessels are 254 feet in length, have a 43′ beam and a cruising radius of 14,800 nautical miles at 11 knots or 5,750 nautical miles at 18.4 knots. They carry a complement of 15 officers and 108 men. Both planes and ships will be equipped with Radar and Loran. It is contemplated that one cutter will be on patrol and one vessel will be on standby status in the vicinity of Argentia.

Information concerning ice, growlers, and icebergs will be collected by the patrol vessels, from aerial surveys, and from sightings reported by ships and planes operating in or crossing the area subject to ice hazards. Whenever practical, commercial ships will be requested to report by dispatch every four hours when in the ice area their position, course, and speed, and a brief description of

* Described in detail in recent issues of Pacific Marine Review.



DRIFT OF ICEBERGS FROM THEIR SOURCE INTO THE NORTH ATLANTIC

ice sighted. This information will be summarized each day in radio dispatches which are broadcast twice daily.

An idea of the importance which mariners in the vicinity of the Grand Banks place on the receipt of ice information is indicated by the cessation of practically all commercial radio transmission during the periods the ice information is being broadcast by the Ice Patrol Commander.

In past years, during periods of poor visibility, when it was not possible to conduct efficient patrols, the ice positions given were estimated and based on sightings that might be several days old but the introduction of radar during this year's patrol will assist in locating bergs even during low visibility.

However, current models of radar gear of proper characteristics and operating at peak performances should easily pick up large ice-bergs but small bergs or growlers capable of doing extensive damage to vessels in even moderate seas and with moderate wind conditions are liable to remain undetected. It is therefore unsafe to rely on radar to indicate small bergs or growlers that may be large enough to sink a vessel. Ships should, therefore, make a practice of keeping clear of areas infested by growlers and heavy pack ice even though scattered. The most certain method of avoiding damage to a vessel is to be able to see ice and keep clear of it.

The introduction of Loran into the ice patrol service this year offers a much better opportunity to check the exact locations of bergs and ice after they are sighted. In the past, patrol vessels have been fogbound for days. Their position had to be determined by dead reckoning and radio direction finder bearings. With the advent of Loran, the patrol vessel's position can be plotted within approximately one mile so fog will no longer interfere with this phase of operations. Loran will also afford a more efficient means of tracking bergs in their early movements.

Besides the regular work of locating the ice and warning passing vessels of the danger limits, the officers of the patrol vessels are directed to make a study of the ice situation, particularly with regard to the currents in the vicinity of the Grand Banks, the physical properties of the ice, its drift, erosion and melting; temperatures of sea water and atmosphere in the vicinity of the ice; habits of birds, and seals with regard to ice; and, in short, to gather all sorts of information that might help the navigator in those regions.

The Coast Guard's many years of experience in administering the International Ice Patrol in the North Atlantic and in conducting operations in Alaskan waters and other areas where heavy ice conditions prevail was put to good use during the war. At the outset of the war, Coast Guard cutters, with their Coast Guard officers and men, were organized into a patrol for the naval defense of Greenland under the operational control of the Commander in Chief, U. S. Atlantic Fleet. This force was later expanded, augmented by the establishment of an operating base, radio stations, aids to navigation, aviation landing fields, and other facilities in Greenland. The Greenland Patrol provided escort vessels for shipping between Greenland and the United States and Canadian ports, carried out anti-submarine activities in these waters, and cooperated closely with the Army in the establishment of bases in arctic and sub-arctic territory. A special duty assigned to this force was that of protecting the cryolite mines in Greenland and of convoying and protecting merchant vessels carrying cryolite to United States ports.

The Coast Guard takes particular pride in its record of service since undertaking this duty; not a single life has been lost by reason of collision of a vessel with an iceberg in the area under surveillance. This record of efficient performance of duty in connection with the Ice Patrol is in keeping with the tradition of the Coast Guard dating back over 150 years, and which the Coast Guard strives zealously to maintain with an unfaltering resolve that the duty shall be carried on in a manner to merit the esteem and respect of the maritime nations of the world.

Briefly stated, the duties of the Coast Guard in conducting the ice patrol in the vicinity of the Grand Banks, consist in finding and keeping in touch day by day with icebergs and field ice, determining their set and drift, reporting their presence and location to the Hydrographic Office of the Navy, and broadcasting the information by radio for the protection of shipping. The cutters, while on this work, also perform such incidental service, not to interfere, however, with the paramount duty of the patrol, as rendering assistance to vessels in distress, giving medical aid to crews of passing vessels, removing obstructions to navigation, and extending such other assistance to the mariner as may be practicable, and conducting scientific observations and experiments for the aid and furtherance of oceanographic knowledge.

This will be a year of new ideas and innovations for combating the ice menace. Changes from the old system of patrol are in order as the result of introducing wartime equipment to peacetime usage in safeguarding merchant shipping.

United Nations Ships May Use WSA Food Stores

Permission has been granted by the War Shipping Administration for vessels of Greece, Netherlands, Norway, Sweden, United Kingdom, and tankers of Panama to stock food stores from WSA sources. Exemption from a previous order limiting supplies to U. S. ships was made possible by an agreement reached by the Department of Agriculture and the War Shipping Administration.

The agreement followed an appeal by Ministries of Shipping of the six nations to the acting war shipping administrator for exemption and stating that it would be impossible for their vessels to obtain adequate quantities of food either in their home countries or through civilian channels in the United States.

The exemption provides that the foreign flag vessels must comply with all other food control regulations and bulletins issued by the Food Control Division of WSA.

Other countries may be included in the exemption agreement if they make application to WSA including proof of inability to obtain food stores in their home countries and other qualifications.

All privately owned ocean-going American flag vessels engaged in foreign commerce and coastwise vessels previously covered are included as authorized purchases of Government controlled foodstuffs from approved ship supplies.

Merchant Ships In Atomic Test

The effect an atomic bomb will have on cargo ships and transports is an important part of the coming world-celebrated experiment to take place in mid-Pacific this summer. One-fourth of the targets will be merchant-ship types.

Besides the 25 targets, 21 other merchant-ship types will participate as survey and supply ships. Among the latter is the Navy transport W H A R T O N, once the liner SOUTHERN CROSS, which carried thousands of tourists to South America. Already on the scene at Bikini Atoll, in the Marshalls, is the BOWDITCH, a survey vessel formerly the well-known SANTA INEZ, of Latin American passenger ship fame. The transport GEORGE CLYMER, once the liner AFRICAN PLANET, will also participate in the supply fleet.

Among the other supply ships heading for the tiny atoll in the wake of some thirty-five warships, from battleships to submarines, are six Victory ships, six C-2 cargo ships, three C-3 transports and three seaplane tenders.

The first ship to arrive at Bikini Atoll was a merchant ship, the SYLVANIA, an attack cargo ship. She reached the scene of the bomb test early in March with a load of buoys and chains for marking areas.

The last ship to arrive will also be a merchant-type vessel, scheduled to be late in reaching the scene for a specific purpose. She is to be the BURLESON, a two-funneled transport playing the part of a modern "Noah's Ark". On board will be over 4,000 animals, to be distributed among the target ships to test the bomb's effect on animal life.

In order to reduce expected seasickness among these doomed creatures, the BURLESON will be held in San Francisco until April 15 when she will begin her high-speed run to the Marshalls. She will carry 200 goats, 200 pigs, some sheep and 3,700 rats.

First to arrive of the $100,000,000 worth of merchant-type ships to be used as targets will be the FILLMORE. She and her 24 sister-ships are two-stack transports and attack cargo vessels, each of over 425 feet in length. They were designed and built by the Maritime Commission. All but two of this fleet were known as Navy BD1's unique in that they were launched complete with superstructure, masts, funnels and boat davits all in place. The other two vessels are combat cargo ships.

During the war, these combat transports and cargo ships formed the core of our amphibious forces in many landing operations. Working close inshore, they discharged cargo and troops on beachheads, at the same time providing considerable fire-power to cover the operations.

Lists of the target and supply ships participating in the test, as furnished by the American Merchant Marine Institute, follows:

Swedish Merchant Fleet 1,600,000 Tons

During 1945 Sweden's merchant marine increased by 41,000 gross tons to 1,598,000 tons, as compared with a net increase of 135,000 tons the year before. Most of the vessels added to the fleet were motor-driven. The steam tonnage, on the other hand, showed a further decrease. The number of ships at the end of 1945 was 2,069, or 23 less than in 1944.

The war losses of Swedish merchant shipping were about 600,000 gross tons. Most of these losses, however, have been compensated by new construction at Swedish yards, and the country's commercial tonnage is now about the same as before the war. Swedish shipyards are also engaged in a large building program for Norway.

At the end of 1945, the make-up of the Swedish merchant fleet was as follows:

	Gross tons
679 steamers	548,558
580 motor vessels	969,483
808 auxiliary vessels	79,676
2 sailing ships	90

Ship Warrants Act Still in Effect

Controls exercised over shipping by merchant ship warrants are still in effect despite termination of the United Maritime Authority agreement as of March 2, 1946.

Public Law 173, Seventy-seventh Congress, commonly known as the Ship Warrants Act, as extended by Public Law 610, provides for the exercise of certain controls over shipping for six months after the termination of World War II shall have been proclaimed, or until such earlier time as the Congress or the President may designate.

Accordingly, until further notice, vessels are required, under the rules and regulations issued pursuant to the Public Laws involved, to hold valid United States merchant ship warrants to be entitled to priority in the use of shore facilities in United States ports.

Seagoing Hopper Dredges

USEO Hull Design No. 248

A shipbuilding project now rapidly nearing completion and one that is different in character from any of the war-time construction to which we have become accustomed, is the construction of four 3000 cubic yard capacity seagoing hopper dredges.

These vessels are to be added to the constantly growing fleet of dredges now being operated by the U. S. Engineers in the development and improvement of harbors where deep water dredging is necessary.

The general design plans prepared by the U. S. Engineers Office, Philadelphia, Pa., reflect the summation of the latest ideas gained from past performance of dredges under their operation and include a great variety of specialized equipment.

Complete detailed working drawings for hull, machinery and electrical work, together with requisitions in detail covering all materials required have recently been prepared by Joslyn & Ryan, Marine Engineers and Naval Architects of San Francisco.

These dredges to be named Comber, Gerig, Langfitt and Biddle are now under construction in the yards of the Ingalls Shipbuilding Corporation, Pascagoula, Miss., under the supervision of USEO inspectors at their yard.

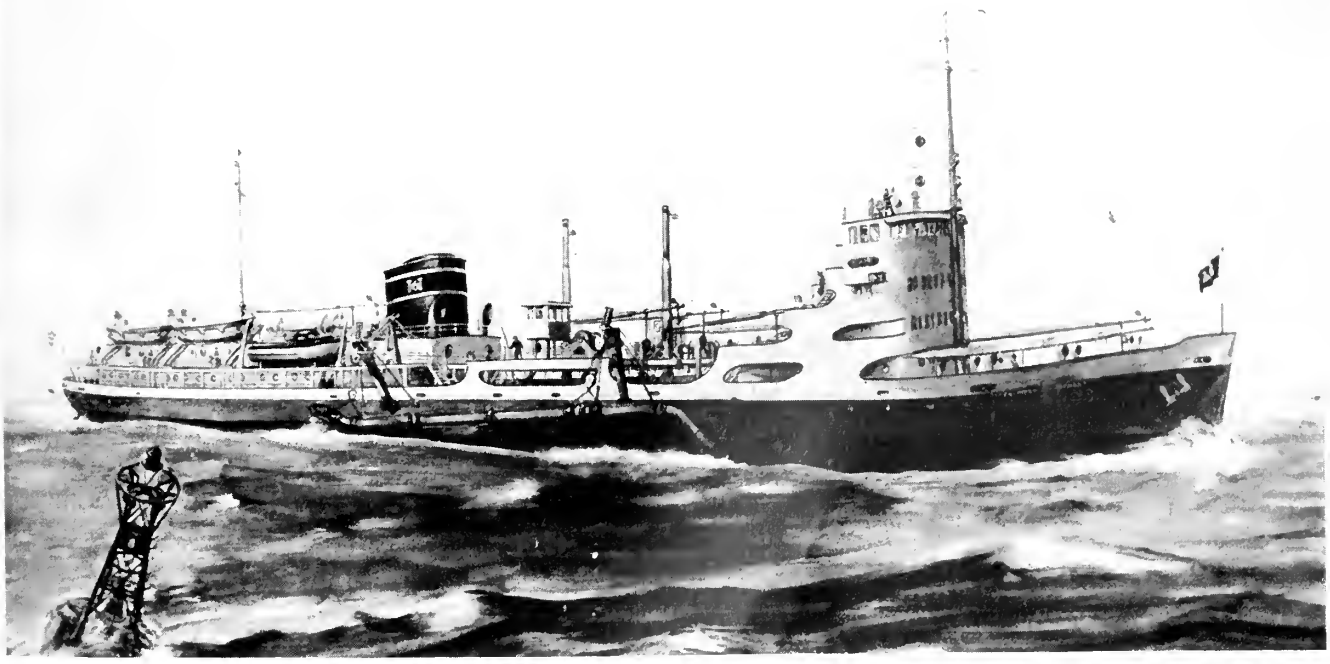
Hopper section, where the muck is loaded from suction pipes for transportation and dumping at sea, is located forward of the boiler room. This hopper section is divided into six main hoppers, extending 91 feet fore and aft and 20 feet port and starboard of center line. Each of the six hoppers is subdivided by transverse sloping bulkheads into 2 smaller hoppers which convey the muck to 6′-0″ x 6′-9″ cast iron doors in the bottom of the hull, which open to the sea. There are twelve such doors, hydraulically operated from walkways at the bridge deck level.

Pump room for dredging operations is located forward of the hopper section and contains two enormous 30″ diameter intake centrifugal pumps port and starboard. Through a trunnion in the shell abreast of the pump room each pump, port and starboard, is connected to the long drag pipe suction line with its draghead chewer at extreme end.

Drag pipes are raised and lowered by cable through huge blocks attached to large davits, which also control lateral position of drag pipes.

Since these dredges were designed to go anywhere for dredging purposes the quarters and accommoda-

The seagoing hopper dredge.



tions for crew and ship's stores are quite extensive and much more complete than on the ordinary work boat. Provision has been made for a complement of 93 persons, which includes not only the usual crew for the operation of the ship but also those handling the dredging operations as well.

Arrangement of accommodations and equipment is designed to adequately supply all the needs of this large crew on long voyages so that these vessels are modern hotels afloat combined with a complete hopper dredge system.

General arrangement plans herewith indicate: the relative location of the propulsion and dredge operating power producing and power applying units; the arrangement and location of the accommodations; the location of emergency and life saving equipment; and the arrangement and location of the waste material carrying hoppers.

A table herewith records the principal characteristics.

Propulsion Machinery

Propulsion machinery employs the turbo-electric system. Two single pass, sinuous header cross drum type water tube boilers, supplied by Combustion Engineering Co., deliver steam at 450 psi. 750° F. temperature to two Westinghouse Electric Corporation turbo-generator sets which in turn generates electric energy to four propulsion motors, each of which is directly connected through 14¾ inch diameter steel shafting to a solid four bladed manganese bronze propeller furnished by Baldwin Locomotive Works.

Boilers

Each boiler under normal power operation produces 38,000 pounds of superheated steam and 3500 pounds of desuperheated steam per hour and must be capable of operating continuously at 25 per cent over this normal rating. These ratings are based on: feed water supply at 300° F; fuel oil of 18,500 Btu per pound; fire room temperature not exceeding 100° F; stack temperature at air preheater outlet 320° F; and boiler efficiency not less than 87.5 per cent. Each boiler has 6900 sq. ft. of heating surface exclusive of water walls, and is designed for a maximum pressure of 500 psi. At the desuperheater outlet the steam condition is 435 psi and 50° superheat.

The boilers are fitted with: Todd wide range burners of the mechanical atomizing type; combustion air preheaters; Diamond, automatic, valve-in-head, soot blowers; automatic feed water regulators; and Hagan automatic combustion control.

General Characteristics

Length Over-all	351′	8¾″	
Length, Between Perpendiculars	340′	0	″

Camber Upper Deck		15	″
Frame Spacing	24″ and 26		″
Dead Rise		4	″
Propulsion S.H.P.	6000		
Hopper Capacity	3000 cu. yds.		

Twin Screw Propulsion
Twin Rudders, providing greater maneuverability at low speeds. Engine and Boiler Rooms located aft.

Two Buffalo Forge forced draft blowers of axial flow design are installed in the boiler room, each blower being capable of furnishing air to both boilers. These blowers take air from the annular space between the stack and the outer casing and deliver it through manually controlled louver dampers at the blower outlets, automatically controlled dampers at the boiler inlets, and the air preheaters to the boiler furnace fronts.

The steam and feedwater circuit from and to these boilers is of the closed de-aerating type which has become practically standard in American marine engineering design. Superheated steam for each boiler goes directly to its main turbo generating unit, through the turbine, into the condenser, through the condensate pump into the de-aerating second stage heater, through the feed pump and into the third stage heater and so back into the boiler. Condensate from the auxiliary condensers also comes into the de-aerating heater.

In normal operation the main feed pumps discharge into a common header from which the feed goes to the boiler through the 3rd stage heater or is by-passed directly to the boilers. Thus either feed pump can supply either or both boilers. Connections are so arranged that either feed pump can be overhauled while the other is still serving the boilers.

The main feed pumps and motors were furnished by Aldrich Pump Co., the 1st and 3rd stage heaters by the Davis Engineering Co., Cochrane Corporation furnished the de-aerating 2nd stage heater, and the standby steam drive feed pumps were furnished by Worthington.

Main Turbo-Generator Sets

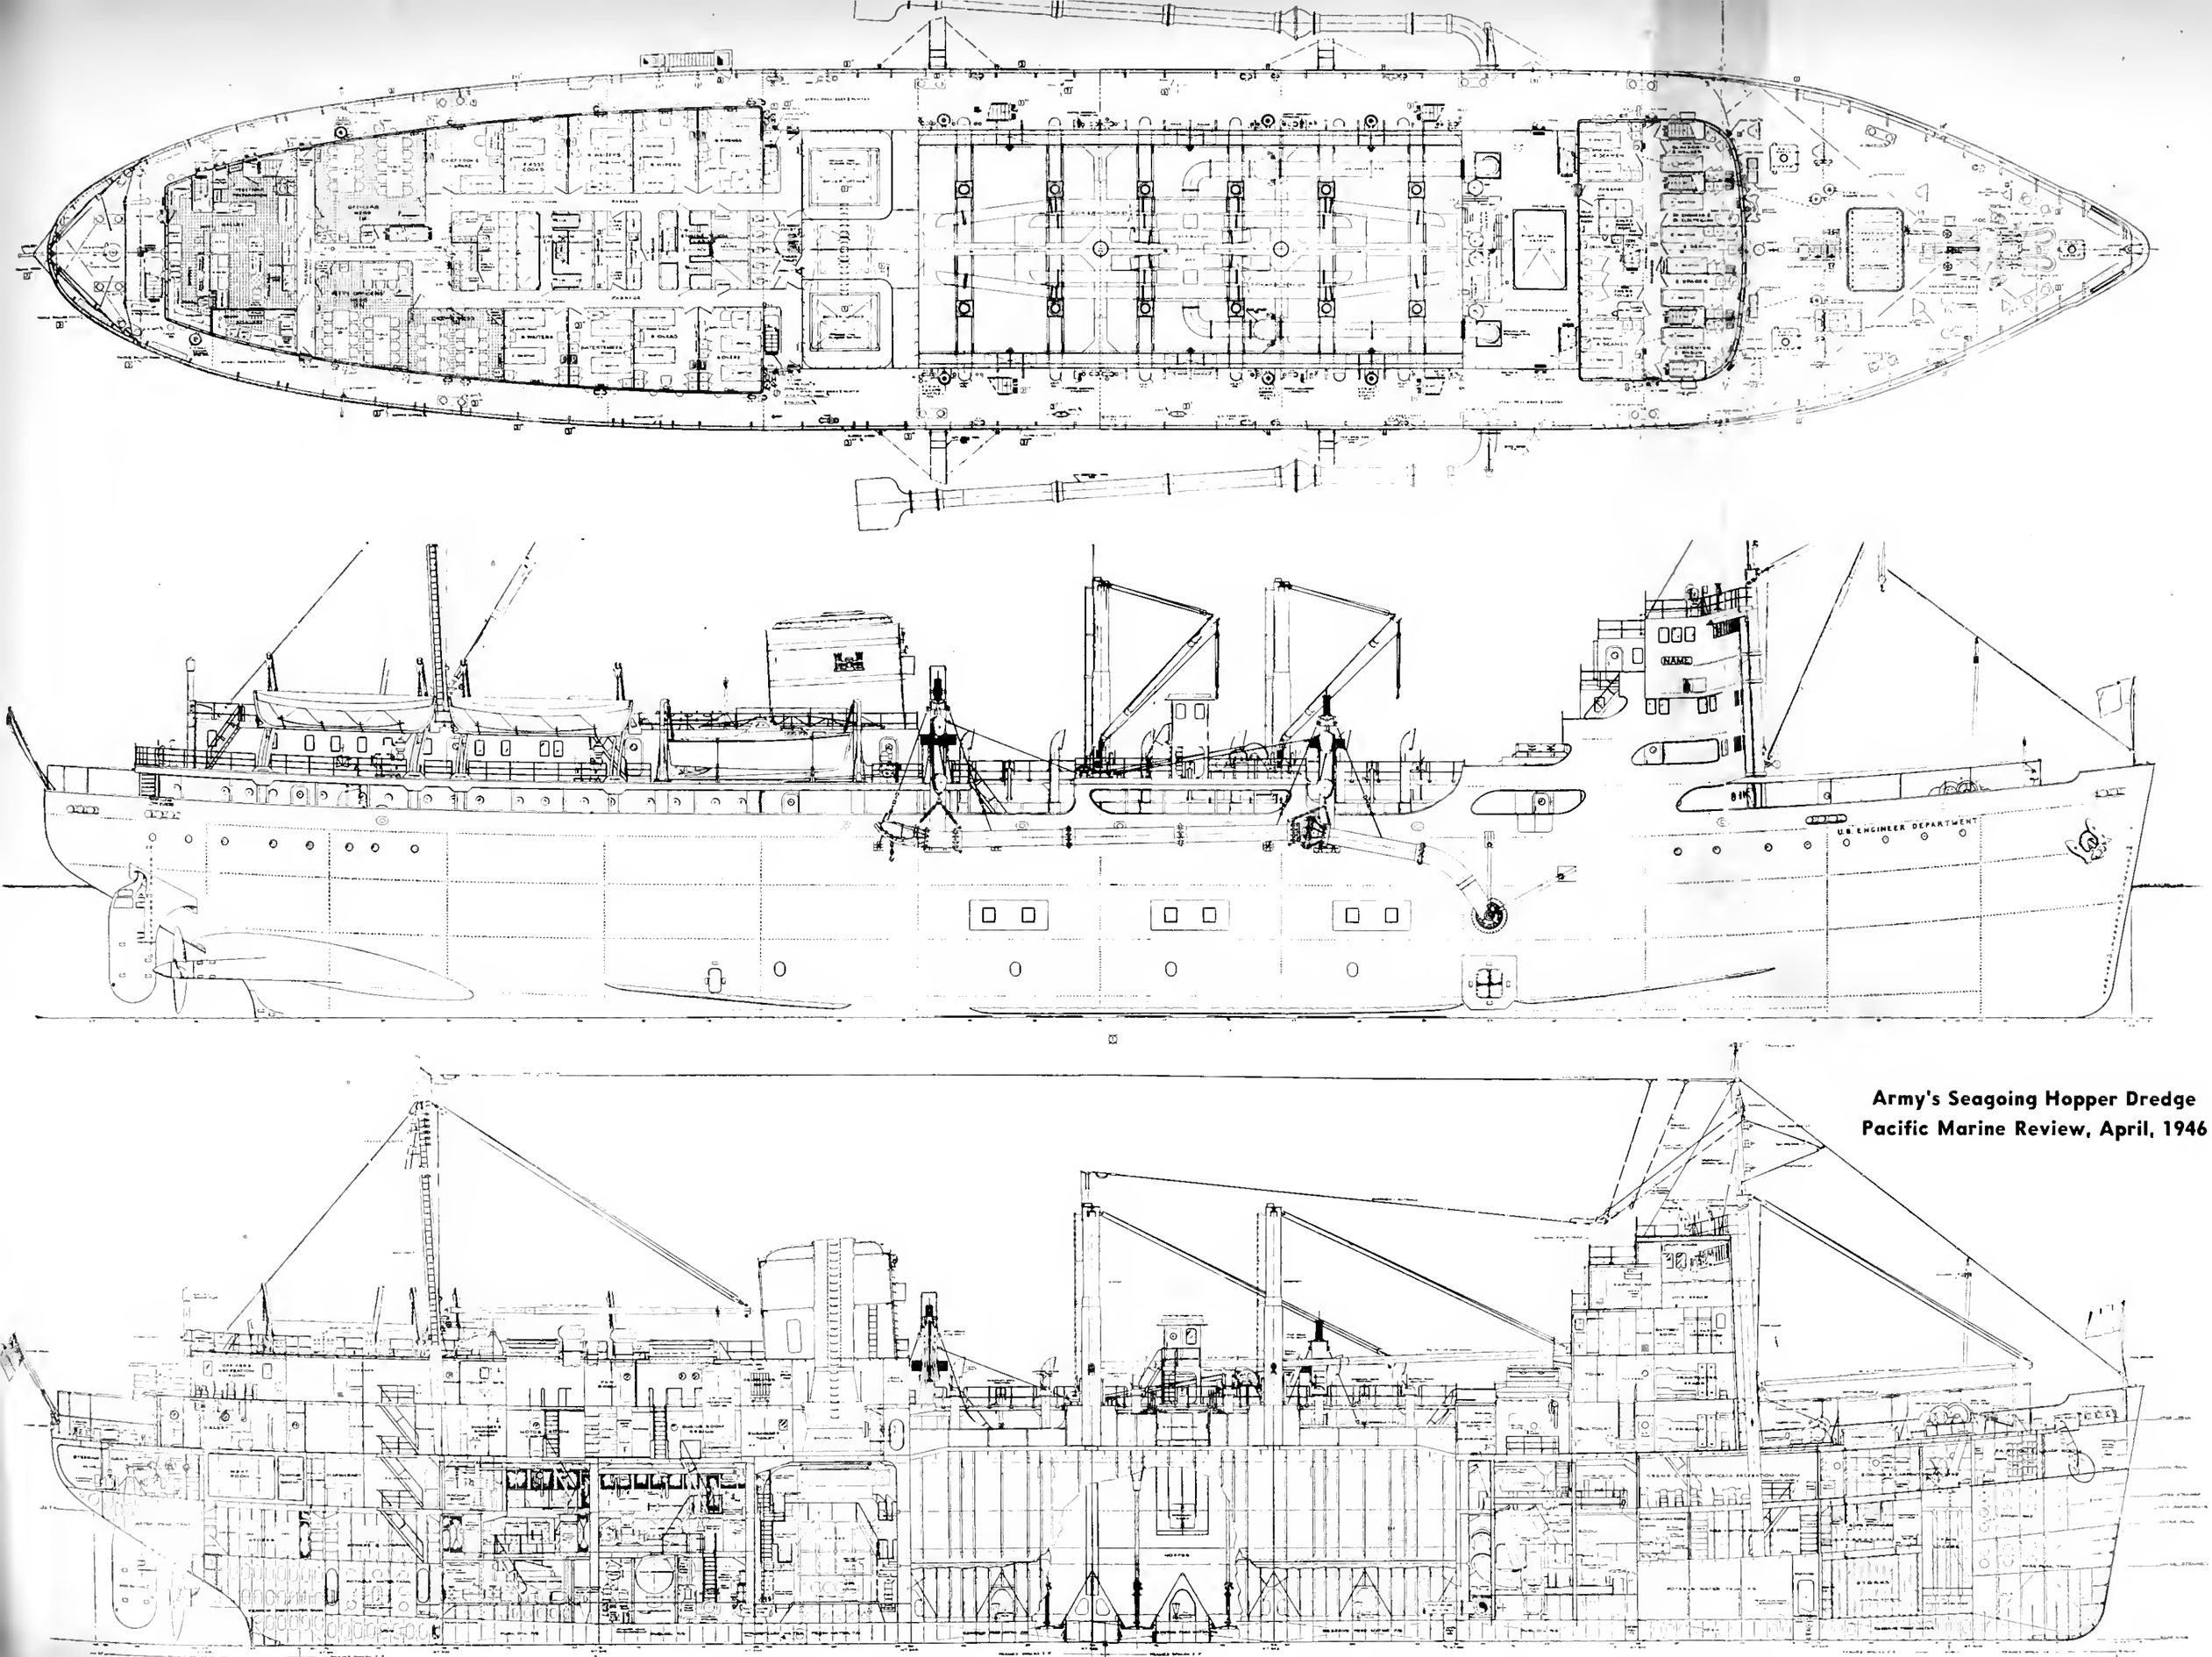
In the engine room just a few feet aft of the boilers are the turbines each having ample capacity to develop on its propulsion motor 3000 shp, plus excitation, all electrical losses, and a 300 kw auxiliary load. These turbines are the standard Westinghouse marine type operating normally at about 6000 rpm and driving through single reduction gears a shaft on which 3 generators are mounted in line. Three extraction connections are provided on each turbine to take off steam for feed water and other heating purposes at 11.8 psi, 30.5 psi, and 83 psi absolute.

The three generators driven by this turbine are: a main propulsion generator; a dredge pump generator; and an auxiliary generator. Electrical characteristics are: for the propulsion generator 600 to 720 volts, 2450 kw direct current; for the dredge pump generator 600 volts d. c. 925 kw; and for the auxiliary generator 240-120 volt three wire d. c. 300 kw. Each generator has a two hour rating of 125 per cent of normal.

The propulsive motors as will be noted on the inboard profile are installed directly below the propulsive generators and are each rated 3000 shp at 100 to 120 rpm. This speed range is obtained by variation of the propulsion generator field voltage within the range of 600-720 volts. Each motor is fitted at the commutator end with a tachometer generator which is wired to an indicator in the pilot house. These indicators accurately show the speed of the propulsion motors over a range from 0 to 125 rpm ahead or astern. On the range between 0 rpm and 100 rpm the propeller speed is under the control of either the bridge or the engine room. Above 100 rpm a constant power of 3000 shp is maintained on each wheel by an automatic regulating unit consisting of one motor and two rotary exciters operating on the fields of the propulsion generators. Each propulsion generator armature is permanently connected with the armature of its respective propulsion motor.

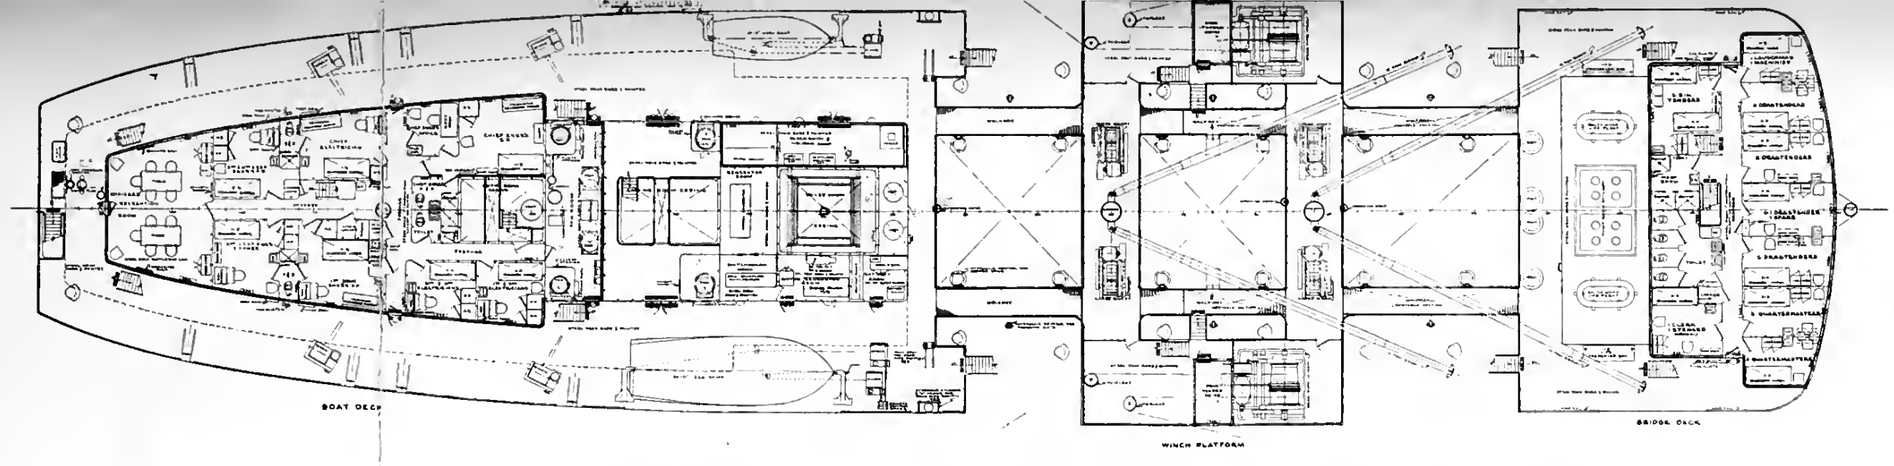
Dredging Equipment

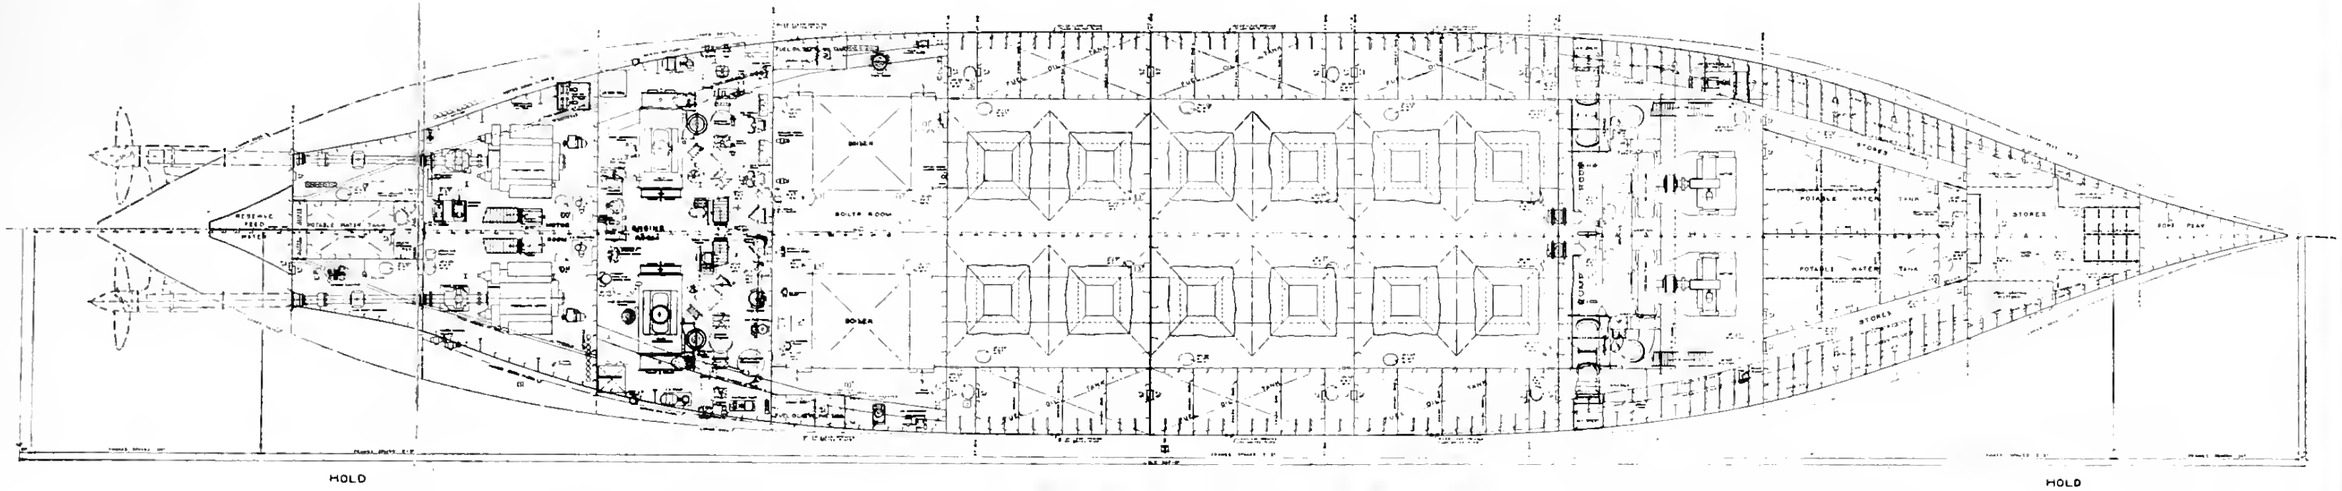
Each of the two dredge pump mo-

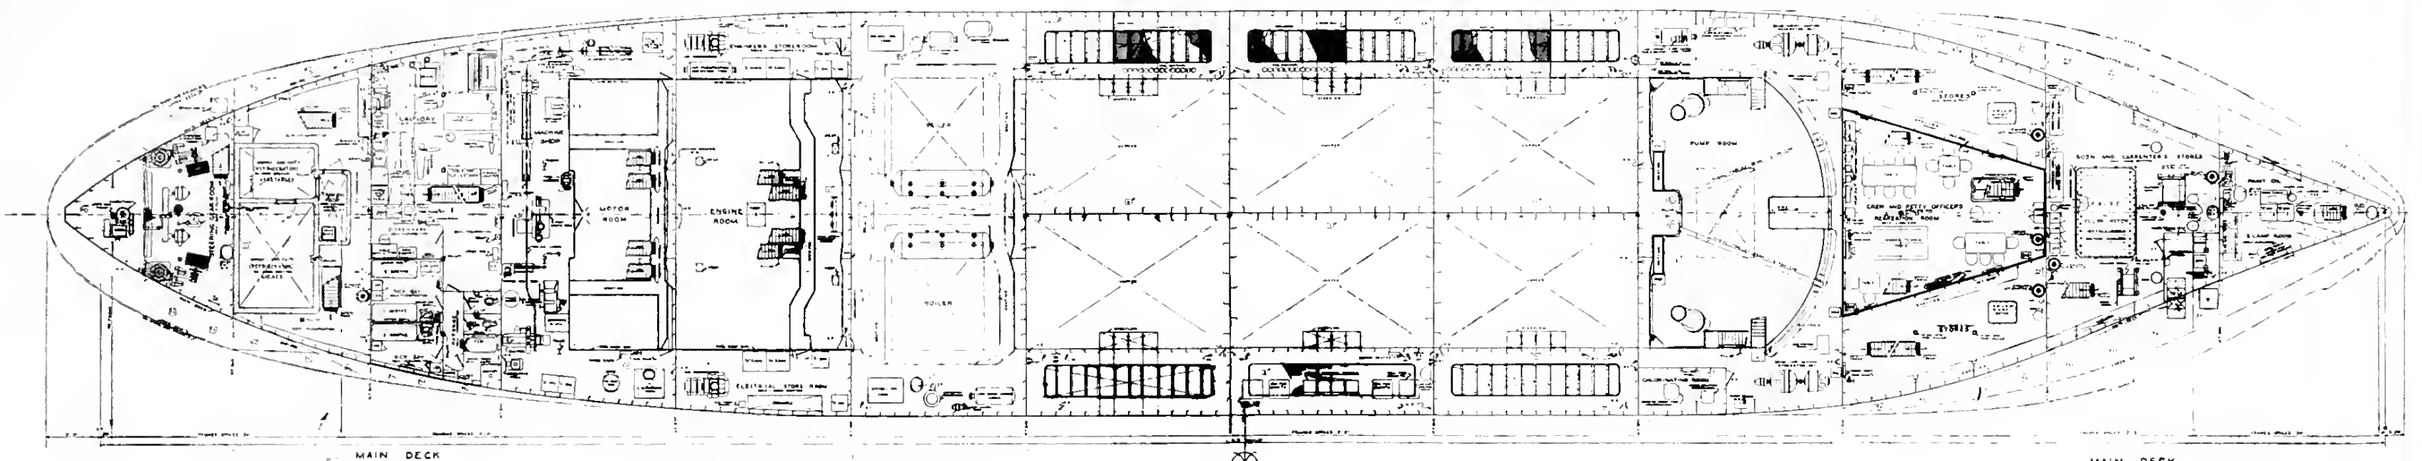


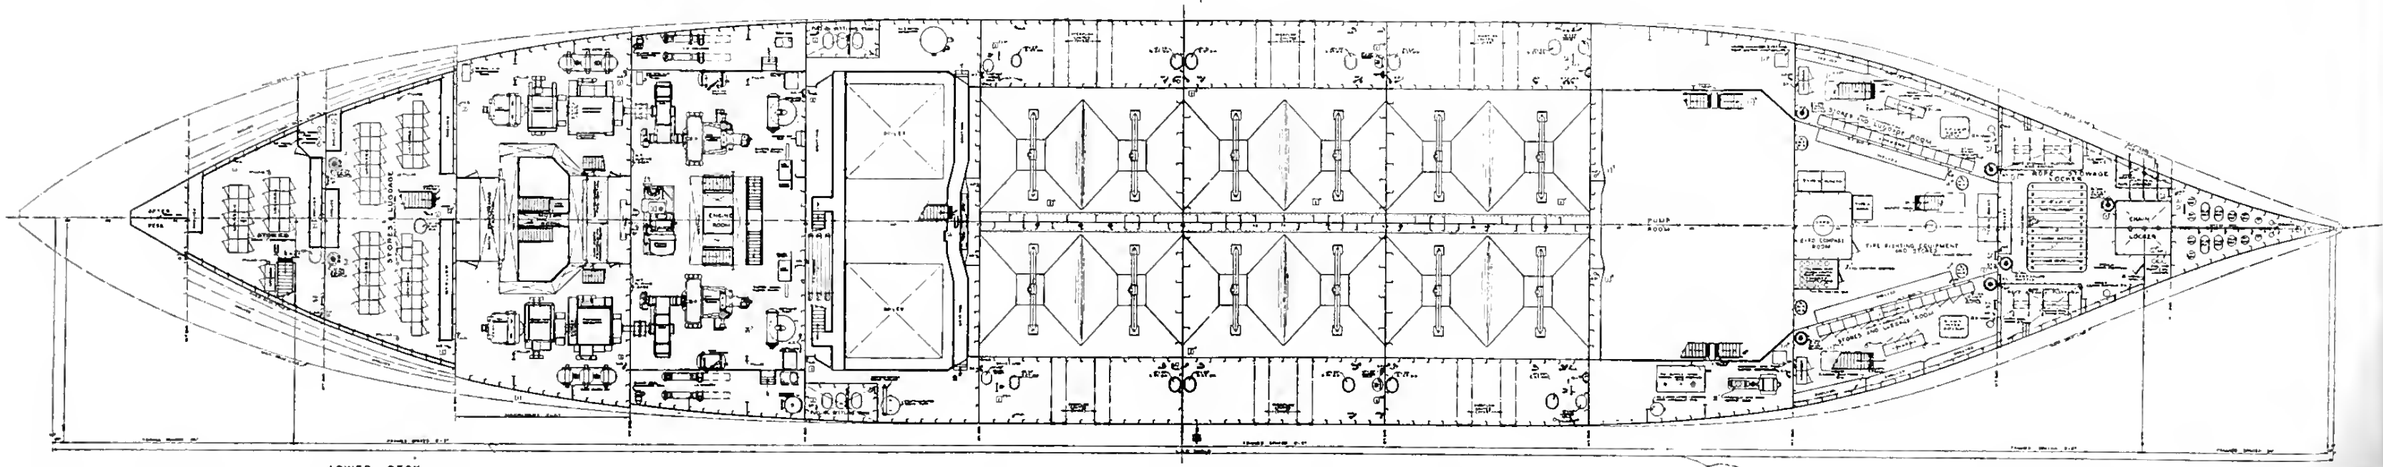
Army's Seagoing Hopper Dredge
Pacific Marine Review, April, 1946

Army's Seagoing Hopper Dredge
Pacific Marine Review, April, 1946









tors is directly connected to its respective dredge pump and is rated 1150 shp at 180-205 rpm, 600 volts d. c. The speed range is controlled through variation of the field voltage of dredge generator. A waterproof drum controller with 20 points of control, located in the drag-tender's house, is used to cut resistors in or out to weaken or strengthen the field of either the motor or its generator. Armatures of motor and its respective generator are permanently connected.

Centrifugal volute type single impeller pumps of 30 inch diameter suction inlet are used for the suction dredging opertion. These are built to special material specifications by the Elliott Machinery Corporation which firm furnished also: the suction and discharge piping; the drag pipe winches and davits; the hopper distribution system; and the unwatering and jetting pump. Discharge piping from these pumps is 28 inches inside diameter. The elbows and fittings on both suction and discharge piping are of cast alloy steel and very massive. Mounted on each of the pumps is a Schutte-Koerting primer of the steam jet exhauster type of a capacity for exhausting the suction line and the dredge pump in 1¼ minutes when operated with steam at 150 psi. Similar priming arrangement is provided for the hopper unwatering and jetting pump.

Outboard suction pipes are supported at their inboard ends by trunnions. From the trunnion an elbow leads into a long bend and a straight section ending in the ball joint followed by a long straight section ending in the drag head. This assembly is of sufficient length so that at a 45° angle it could be used on bottoms 55 feet or more below the surface of the sea. In operation each of these outboard suction pipes is supported by wire rope falls from two davits, one supporting the ball joint and the other supporting the drag head. These davits are served by a winch with two drums driven by a 125 shp, 230 volt, shunt wound d. c. motor rated at 690 rpm. In order to get the delicate control required for this operation each winch motor is provided with a motor generator set consisting of a 150 shp 240 volt d. c. motor driving a 113 kw 240 volt d. c. generator and rated at 1200 rpm. Each winch motor when working in either direction is controlled by varying the field of the generator of its respective motor generator set. This is accomplished by means of a pilot exciter energizing each generator field and so designed that its output can be controlled by a self-contained auxiliary circuit. Each auxiliary circuit is controlled by a rheostat mounted in a pedestal control stand in its respective drag-tender's house. Thus by a very simple manual movement the winch is under perfect electrical control. The two drums on the winch are so proportioned and geared that they automatically take care of the relative positions of ball joint and drag head without putting any undue strain on the pipe.

Deck Machinery

A motor drive spur gear windlass with two winch heads and suitable for 2 3/16 inch stud link anchor chain is located on the upper deck forward. The Westinghouse motor is rated 50 hp at 230 volts d. c. The windlass is by the McKiernan Terry Corp., and it is capable of hoisting two 7070 lbs. bower anchors and two 20 fathom lengths of 2 3/16" anchor chain at a speed of four fathoms per minue. Anchor chain is cast steel by the National Malleable & Steel Castings Co.

A vertical single barrel motor drive capstan capable of producing a pull of 11,000 lbs., with a line speed of 40 ft. per minute and of working a load at crawling speed without unsnubbing, is installed on the upper deck aft.

Six double reduction spur-geared electric drive American Hoist and Derrick Co. cargo winches are installed as follows: one on upper deck forward; four on boat deck winch platform; one on upper boat deck house top. The upper deck forward is capable of 5000 lb. line pull at 100 ft. p. m. and of 6000 lbs. at reduced speed. All the other winches have a line pull capacity of 10,000 lbs. at 100 ft. p. m., and 12,000 lbs. at reduced speed.

These vessels are equipped with two large rudders hung as shown on the outboard profile. These rudders are operated by an American Engineering Co. hydro electric steering gear. The rudders are spaced 8 ft. 6 in. outboard of center line port and starboard. The gear is capable of moving both rudders simultaneously through an arc of 70° in 30 seconds at a vessel speed of 15½ knots (light condition). Control from the pilot house and the after boat deck-house top is by Sperry electric telemotor. A Sperry rudder angle indicator is installed in the pilot house.

Emergency Equipment

Six boats are carried, four Welin lifeboats on Welin McLaughlin gravity type davits, and a sea skiff and a work boat on Welin boom mechanical type davits. Welin boat winches are installed for handling all boats. The sea skiff is an elaborately fitted cabined cruiser with 165 shp diesel engine drive. Each lifeboat has a 52 person capacity.

For fighting fire there is installed a fire main fed by powerful motor drive pumps and having hose connections to cover all parts of the vessel. There are in addition a number of remotely controlled and a number of manually operated carbon dioxide systems. Remote control systems cover: paint, oil and lamp room; hold spaces; under boiler room floor; and engineers' paint and oil room.

Manually operated systems cover: gyrocompass compartment; pump room at lower deck level; boiler room; propulsion motor room; engine room; and each of the crew's spaces.

Navigating Equipment

Three Navy standard magnetic compasses, an electric deep sea sounding machine, a taffrail log, and a Clinometer were furnished by the Kelvin and W. O. White Co.

An electrical draft indicating system was furnished by the Pitometer Log Corporation. The engine room telegraphs were provided by Bendix Aviation Corporation, who also installed the rudder angle indicators. Guided Radio Corporation sound detecting and talking system is installed. A sound powered selective ringing telephone system connects the pilot house with all essential points in the vessel.

A complete Sperry gyrocompass installation assures correct bearings and includes: one master gyrocompass, Mark XIV model, in a gyrocompass room located on lower deck level directly below the bridge; one bearing repeater atop pilot house; one repeater in pilot house; one repeater in radio direction finder; and one repeater at emergency steering station. A Bludworth marine model radio direction finder is installed in the chart room.

Complete radio telegraph apparatus for transmitting and receiving is installed in the radio room and a complete ship to ship and ship to shore radio telephone service with

remote controls for transmitting and receiving calls in the pilot house. A recording echo sounding device is located in the chart room.

Machine Shop

On the main deck as shown in the general arrangement plans is an elaborately fitted-out machine shop with the following machine tools:

A Le Blond gap lathe 18″ - 38″ swing, 10 feet 2″ bed, motor drive:

A Le Blond screw cutting lathe 12″ size, motor drive;

A Stauss & Haas shaper, 20″ rapid traverse, motor drive;

A Stauss & Haas pipe and bolt threading machine 1″ to 6″ pipe motor drive;

A Moore Handley sensitive drilling machine, motor drive;

A Moore Handley hack saw, 9″ x 9″ motor drive;

A Stauss & Haas radial drill press motor drive;

A Hisey Wolf grinder motor drive;

A blacksmith forge;

A Westinghouse arc welding set;

A machine shop vise;

An Acetylene welding outfit;

An anvil;

Chain trolleys and rails;

And a fine assortment of hand tools and portable electric tools.

Accommodations

Captain and deck officers are quartered on the upper bridge deck, and directly below these quarters on the upper deck level are the ship's crew. In the boat deck house aft are the staterooms of the engineers, and electricians. Directly below these on the upper deck are: the oilers, wipers, waiters, and cooks; the galley and three mess rooms—officers', petty officers' and crew's. Ample provision is made for showers and toilets, not more than 4 persons are assigned to any space. More than customary ventilation and fenestration are provided. Cold storage chambers are provided for ship's culinary stores with refrigeration machinery furnished by York.

Plumbing fixtures and fittings are largely by Crane.

It will be noted from the foregoing description and the plans herewith that these four seagoing hopper dredges are independent units capable of taking care of their crews, their transportation to the job, and extensive dredging operations anywhere in the world that is accessible to vessels of their draft. They are in fact the most complete and elaborate dredges yet built by the U. S. Engineers Office.

Design for Welding And Welding Controls

By R. F. Grambow

A Naval Architect's prime concern regarding welding is the assurance that the completed hull structure conformed to his specification and that each joint was performing its calculated stress without failure and with the proper factor of safety. In order to achieve this end he must first design the hull in such a manner as to facilitate assembly, to eliminate the necessity of excessive field plate edge preparation, to eliminate potential notch conditions, to eliminate inaccessible welds and to minimize overhead welding, to eliminate doubler plates, etc.

With this accomplished, the next step is to establish rigid welding control in order to insure that the design is adhered to and that the prescribed welding procedures and sequences are followed. The final assurance of the success of this control then rests in the proper inspection of the completed weld.

Design

At Marinship our first step was to carefully scrutinize the contract plans with the thought in mind of standardizing weld bevels, eliminating staggered butts, eliminating notch conditions in the main strength members (especially the sheer strake), removal of all attachments or miscellaneous foundations and outfitting items from the sheer strake, and in general simplifying awkward and troublesome welding details. In cooperation with the Welding Division, the Engineering Department developed approximately 30 typical standard welding details which were chosen to include every possible type of weld on the hull. By following this system it was not necessary to detail the welds on any of the structural plans; instead, a particular joint would be identified by the number of the standard weld bevel which would apply. To facilitate operations in the shops, and to eliminate the necessity for constant reference to the design drawings, a cutting sketch was made for all flat rectangular plates and straight shapes. This cutting sketch indicated cutting dimensions, bevels, excess stock and piece mark. In cases where the plates or shapes had shape, templates were provided bearing this same type of information. Following this same practice of giving selective information to the shops, individual shop assembly drawings were developed After the completion of such plans they were turned over to the Welding Division to determine a sequence of welding. It was after this step that actual work on the steel began. A weld layout group would then actually mark this combined information on the steel for the guidance of burners and welders. In this manner a relatively rigid control was attained. No burning or welding could be done until the weld layout man, who came under the supervision of the welding engineer, had transferred the engineering information and the welding sequence from the plans to the steel.

Welder Classification

These precautions although rather far reaching were of little value without proper classification of the welder himself. We all realize that although a welder may complete a very satisfactory job on a down hand butt weld, he may fail on an overhead butt or a vertical weld. In view of this factor Marinship took special precautions to go further into welder classifications than required by the American Bureau of Shipping and the United States Coast Guard and actually classified each welder for a specific type of job.

Regardless of the ambitious control program that was attempted, we realized that because of lack of sufficient and proper supervision because of the intense pressure of the wartime program, we still could not be sure of the finished product. Frequent visits to the yard uncovered many deviations and variations from our planned way of doing things. We realized that the final analysis rested in proper and adequate welding inspection. This inspection fell into three categories: visual, physical and radiographic.

Inspection

At the beginning of our program we relied chiefly on the first two of these. Visual inspection covered such things as under-cutting, over-welding, pitting, unsatisfactory reinforcement, saddle welds, etc. Physical inspection included test coupons, tre-

Marinship Technique

R. F. Grambow of Marinship Corporation, Sausalito, California, presented a paper entitled, "Creation of a Shipyard for Welded Construction" at the February 15 meeting of the New York Section of the Society of Naval Architects and Marine Engineers. After describing the organizational techniques of Marinship and the physical equipment of the yard, this paper describes the design features and the control and inspection of welds which resulted in the practical elimination of structural failures in Marinship built vessels. This article is that portion of the author's paper which deals with welding design and welding controls.

panning, and in some cases, chipping. The men on the ways were naturally seeking some way of eliminating trepanning and in this respect they had the full sympathy of both the welding engineer and the Engineering Department. It was felt that plug-cutting was unsatisfactory and, in fact, bad practice. Welding the hole, we felt, did nothing but set up further stresses in a structure already stressed some incalculable amount. We realize that although the plug was a true sample for one particular spot, the weld one foot away could be entirely different in nature; further, if the plug did indicate an unsatisfactory weld, we had no way of knowing the extent of the unsatisfactory weld without cutting further plugs, or chipping. In such cases we would set out on a chipping expedition, chipping until we came to sound weld and in many cases then chipping further to make certain that sound weld continued, all of which was a costly operation and in many cases an unnecessary one.

We felt that radiography might be the answer and we embarked upon a program of experimentation. To this end the services of the Industrial X-Ray Engineers were obtained. This organization had successfully applied radiography in other west coast yards and we considered ourselves fortunate to find them available. We believed that if we could see through the metal there was not any necessity of cutting plugs.

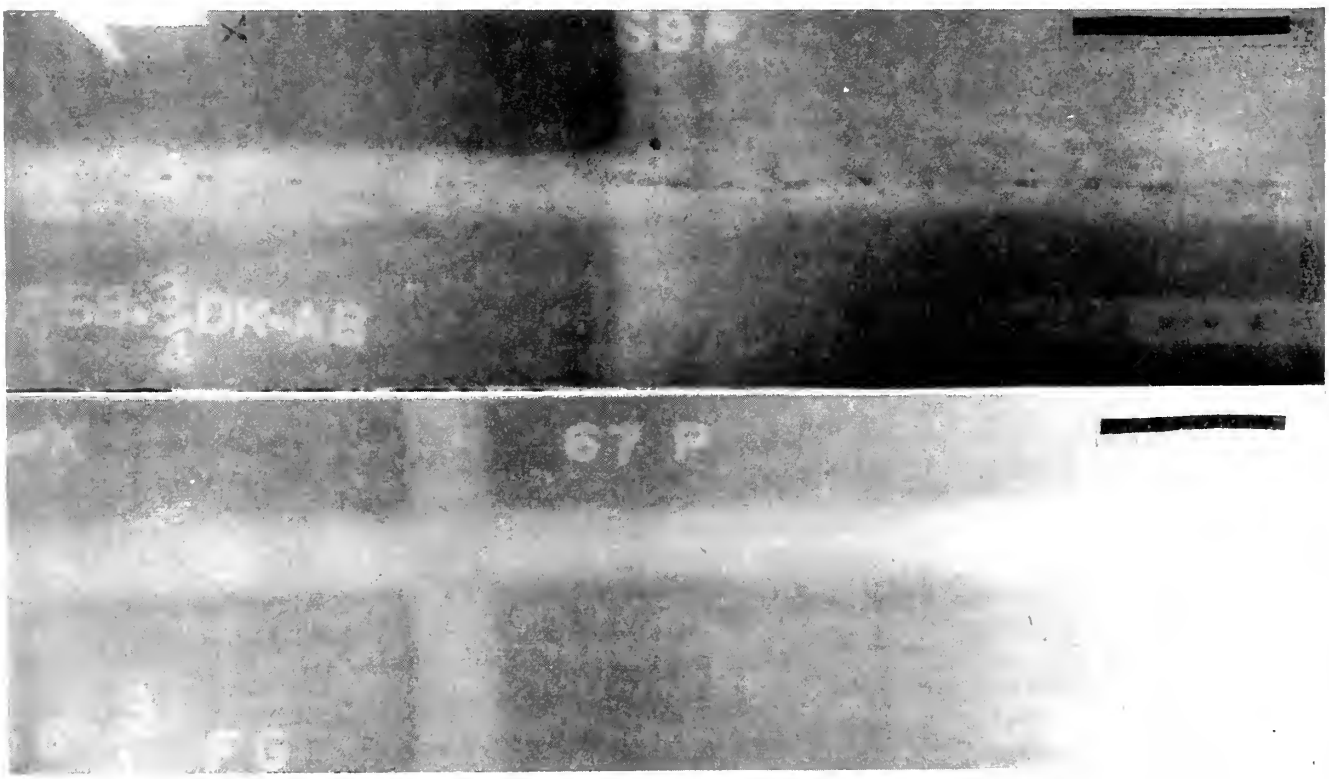
The first question that arose upon deciding to apply radiography to structural welds was, "How much of the hull shall we attempt to investigate?" Our answer was to go far enough to know what quality of welding we were getting and far enough to be certain that the design requirements of the main strength members were being met. In close cooperation with the United States Maritime Commission, the American Bureau of Shipping and the United States Coast Guard, the Marinship Welding Division and the Engineering Department agreed upon which portions of the structure were to be included in the so-called vital area. This area centered around the midship half length, where stresses were known to be a maximum, but also included certain welds at the forward and after portions of the vessel. Within this zone a basic group of approximately 50 butt-welds were chosen to be radiographed.

Both X-rays and Gamma-rays were used. Gammagraphs were preferred because of the relatively simple and compact equipment, the absence of the need for elaborate preparations, and the overall speed of operation. X-ray was comparatively bulky (crane facilities were required for handling it), it was often difficult to support the tube head properly, and the overall operation required more man-hours than radium. In either case similar safety precautionary measures were necessary. The Industrial X-Ray Engineers followed their established rules for the safe handling of their equipment and the shipyard provided guards to divert the workers from the area being inspected.

Each negative was marked to indicate the frame, plate and strake so that it could be readily correlated with the shell extension or deck plating plan. A lead arrow was placed alongside the weld to indicate the forward end. A 9 hole penetrameter of the stop type, graduated in .010", was used. The penetrameter was

Fig. 1 top: This radiograph reveals a deck butt having lack of penetration and slag throughout the length of the film. In addition, a lack of penetration is revealed in the Unionmelt seam going forward of the butt. The location of the lack of penetration in respect to the cover passes of the weld reveals faulty back chipping as the cause of the lack of penetration. The decreasing density of the vertical pockets in the Unionmelt indicate improper "run-out" pads and also that good metal will be reached approximately 6" forward of the butt.

Fig. 2, bottom: Radiograph reveals faultless welding of both the Unionmelt seam and butt. Identification on film shows the radiograph to have been taken on Hull No. 67 port side at Frame 56-3 4 at junction of "F" and "G" Strake.



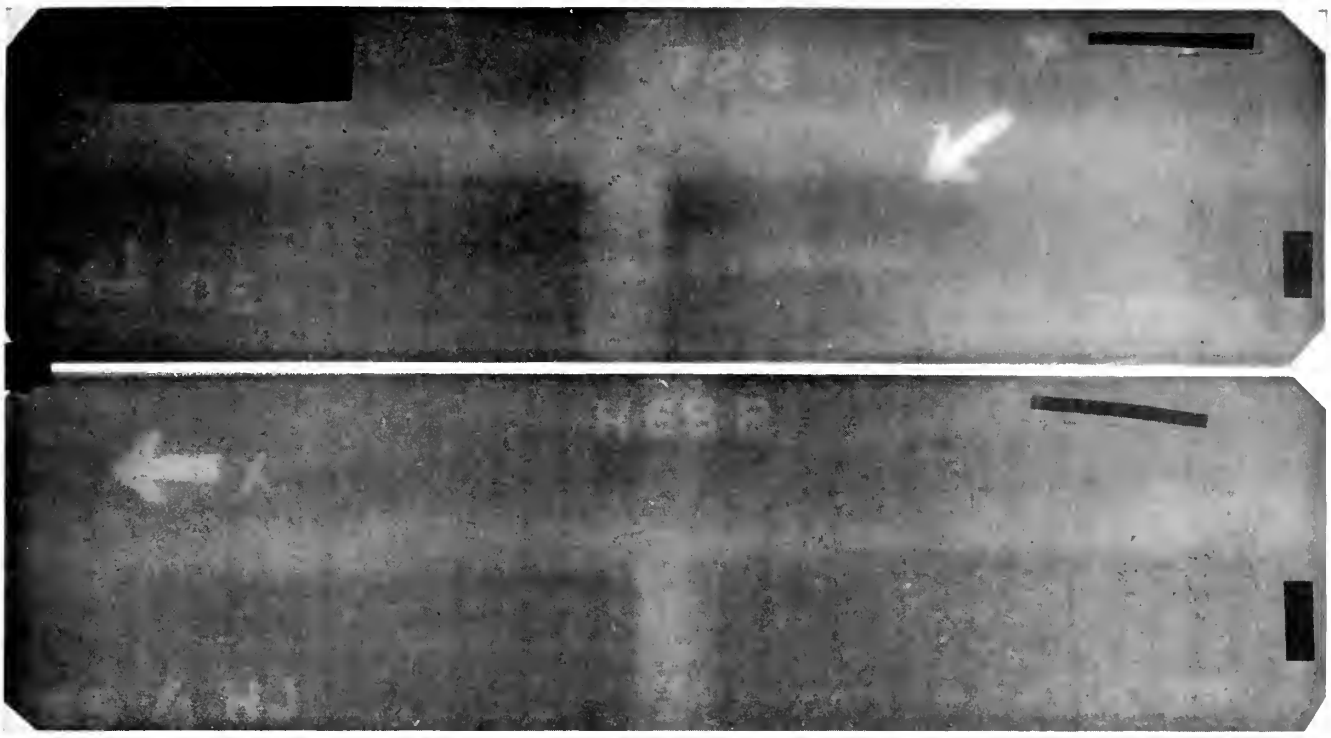


Fig. 3, top: A slight lack of penetration near the top of the "V" of the butt is noted near the intersection. The seam aft of the butt shows gas pockets which are local in character and the film is classified "SUBSTANDARD."

Fig. 4, bottom: Reveals good welding except for minor slag pockets. Note that the .010 layer of the nine hole penetrameter is revealed.

placed on the radium side of the weld. With the use of fine grain films a perception of less than 2% of the thickness of the material was obtained.

In order for radiography to be at all useful it was realized that some set of standards must first be established and agreed upon by all agencies involved. Based upon the experience of the Industrial X-Ray Engineers, in combination with specific known conditions at Marinship, we adopted four classifications of welds.

1. FAULTLESS—a weld showing no inclusions, under-cutting, cracks or defects of any kind with adequate but not excessive reinforcement. (See Fig. 1.)
2. SATISFACTORY—a weld which did not reveal evidence of cracks of any length, and which was free of linear defects of more than 1", slag inclusions, even though they were fairly dense (but were surrounded by several inches of good material), were allowed in this classification. Under-cutting and other surface flaws did not affect this classification but were noted. In some cases it was necessary to check the welding procedure in order to properly identify markings that appeared to be defects. (See Fig. 2.)
3. SUB-STANDARD — defects in excess of those coming in the "Satisfactory" classification but not of serious enough nature to be classed as "Unsatisfactory." However, if the defect occurred in an area where maximum joint efficiency was a requisite, this class of weld was called to the attention of the welding engineer and the inspection agencies to determine if repair of the weld was warranted. (See Fig. 3.)
4. UNSATISFACTORY — radiographs showing linear defects of over 4" on the film, especially these which extended through the end of the film. A chain of slag inclusions, porosity, or pipes were considered the same as linear defects. Cracks of any kind required repair. However, care had to be exercised in differentiating between lack of fusion and an actual crack. (See Fig. 4.)

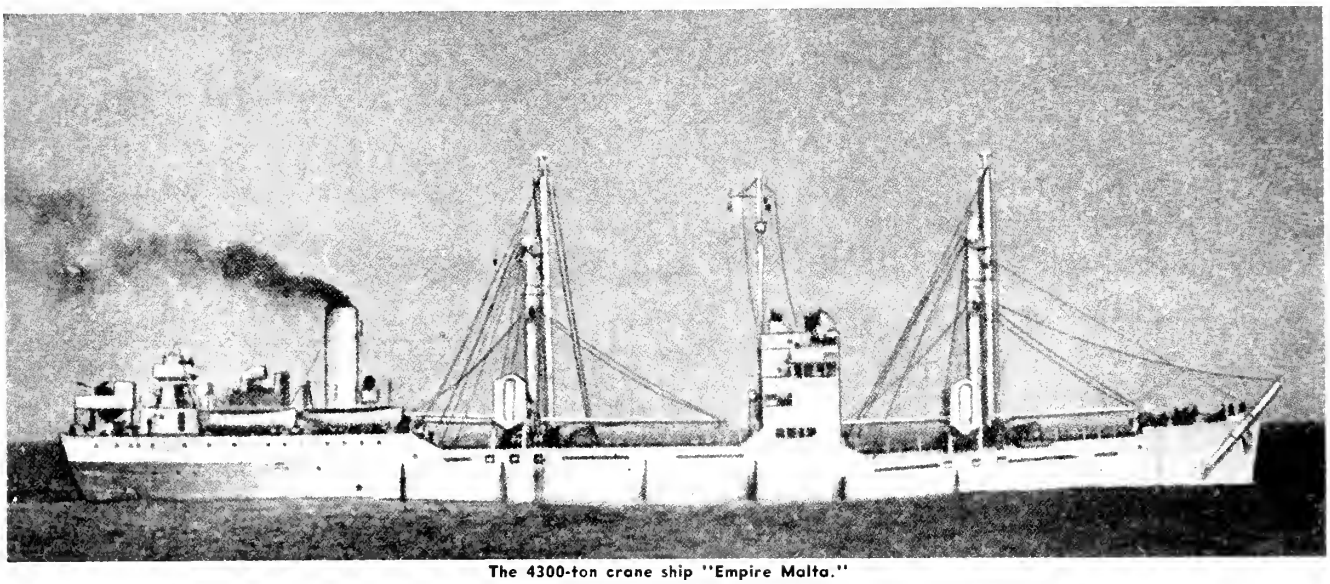
It should be noted that "Sub-Standard" or "Unsatisfactory" welding was submitted to the welding engineer for two main purposes:

1. So that he could review the function of the particular weld as defined by the original engineering design and then determine if the joint as evaluated by the radiograph was acceptable or if it required repair, bearing in mind that in many cases the "cure" of the defect might result in a condition worse than the defect itself.
2. So that the "Sub-Standard" and "Unsatisfactory" work could be discussed directly with the welding supervisors who were responsible for the quality of the joint, and who could in turn contact the welder who actually did the work.

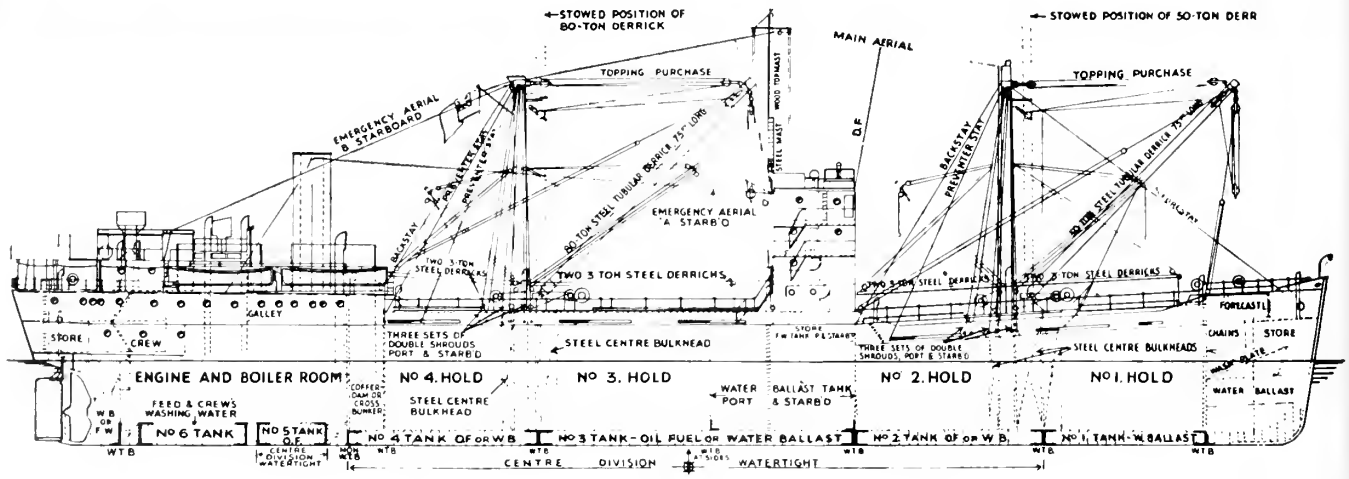
There is one very necessary link that must be present in order to derive the maximum control offered by radiography. Some means must be provided so that the welder who made any particular weld can be identified. This was accomplished at Marinship by a very simple card system which allowed us to know **who** and **what** on each hull. Each hull erection section was represented by a master card bearing the same identifying number as the section itself. Each of these master cards was supplemented by a secondary set of detailed cards which enumerated the various shipfitting and welding oper-

(Continued on page 368)

A Multi-Purpose British Steamer



The 4300-ton crane ship "Empire Malta."



Built by Wm. Gray & Co., Ltd., West Hartlepool, for the Ministry of War Transport in 1944, the Empire Malta was the prototype of a special series of multi-purpose ships designed by the Merchant Shipbuilding Department at the Admiralty to serve, according to requirements, as crane ships for lifting cargo weights up to 80 tons, as cased-oil carriers, as colliers, or as general purpose cargo vessels, or for carrying heavy vehicles.

Of the well deck type with poop (82 ft.), raised quarterdeck (197 ft.) and forecastle (29 ft.), the Empire Malta has the following main particulars:

Length, b.p.	312 ft.
Breadth moulded	46 ft. 4 in.
Depth mld. to upper deck	24 ft. 9 in.
Depth mld. to raised quarter deck	29 ft. 7 in.
Gross tonnage	3,539
Net tonnage	2,265
Deadweight tonnage	4,310
Draught	20 ft. 10 in.

She has four cargo holds served by large hatchways—one 40 ft. 6 in. long by 26 ft. wide—the total grain capacity being 250,700 cu. ft., and bale, 240,000 cu. ft. No. 1 hold is 40 ft. 6 in. long, No. 2 hold 47 ft. 3 in., No. 3 hold 78 ft. 9 in., and No. 4 hold 38 ft. 3 in. The hatchways are of the following dimensions:

No. 1 hatch....24′ 9″ long by 20′ wide
No. 2 hatch....24′ 9″ long by 26′ wide
No. 3 hatch....40′ 6″ long by 26′ wide
No. 4 hatch....22′ 6″ long by 26′ wide

The transverse bulkheads separating No. 3 hold are fitted with portable sections port and starboard, giving clear access to No. 2 hold and No. 4 hold respectively, the openings in each case being 14 ft. wide and 20 ft. high above the tank top, or 14 ft. high above ballast. These openings enable the vessel to carry in three holds large vehicles, tanks or locomotives which, owing to their size, could only be loaded through the one hatchway. In addition to the total water ballast capacity of 1,327 tons provided in the forepeak, double bottom tanks and side tanks in way of No. 3 hold, 100 tons of permanent ballast are arranged amidships to assist in limiting the angle of heel when heavy lifts are being made.

Cargo-Handling Gear

The cargo-handling gear is grouped round the foremast and the mainmast respectively (there being also a light wireless mast immediately abaft the bridgehouse). The forward cargo-handling gear consists of four 3-ton derricks, one 50-ton tubular steel derrick, 75 ft. long, two 7 in. by 10 in. steam winches and two 8 in. by 12 in. steam winches geared to large barrels for lifting heavy loads. There is a similar arrangement at the mainmast, which suports the 80-ton derrick, also 75 ft. long. When either of the heavy derricks is in use, two of the 3-ton derricks serving the same hold (No. 1 hold and No. 3 hold, respectively) are unshipped. The topping purchase for the 50-ton derrick runs through a 16 in. quad iron block at the masthead and another on the derrick, and the two main cargo purchase blocks are also of 16 in. quad type. The purchase arrangements for the 80-ton derrick are similar, except that 18 in. blocks are used. No departures from accepted practice were made in the cargo leads and runs so that normal crews would have no difficulty in working the heavy-lift gear.

The officers' and engineers' cabin and saloon accommodation in the Empire Malta, which was intended for continuous service in the tropics, is arranged in the bridgehouse. The crew and defense personnel are housed aft, 10 defense personnel on the poop deck and the native crew—comprising 23 for deck duties and 14 engineroom—on the raised quarterdeck.

The machinery of the Empire Malta was supplied by the Central Marine Engine Works of the builders and consists of a set of triple expansion engines with cylinders 20, 31 and 55 in. diameter by 39 in. stroke, steam being supplied by two oil-fired boilers, 14 ft. by 11 ft. 9 in., working at 200 lb. pressure and fitted with forced draught and superheat. The service speed is 11¼ knots on 15¼ tons of oil fuel per day.

The ILO's Maritime Work

By J. L. Mowat

Acting Chief of the Maritime Service of the International Labor Office

Following the recent meeting in Copenhagen, the representative of the American shipping industry very strongly urged that the Seattle meeting be taken very seriously and attended with adequate preparation.—Ed.

In the more than twenty-six years of its existence, the International Labor Organization has done much to raise the international standards of employment of seamen throughout the world. That is part of its job, which is in general to help to maintain peace by guaranteeing fair conditions of employment for all workers and thereby reducing international competition based on unfair working conditions. Now that the war is over, the Organization is again getting down to the task of making further improvements. At a conference to be held in Seattle, Wash., beginning June 6, it hopes to set up a number of new international rules to get better conditions on board ship and to promote the well-being of seamen in a variety of ways.

How the ILO Works

Under the ILO's machinery international standards for conditions of work in various occupations are formulated by the International Labor Conference—a kind of world parliament for discussing labor and social questions. In normal times general sessions of the Conference are held every year. In addition, from time to time there are special maritime Conferences which bring together as delegates experts on the shipping industry and on life at sea. Each Conference has before it reports prepared by the International Labor Office, which is constantly collecting and distributing information on all aspects of labor problems. In its work in connection with seamen, the Office is advised and guided by the Joint Maritime Commission—a standing committee of nine representatives

of shipowners and nine representatives of seamen chosen from different maritime countries.

When the Conference meets, whether to discuss general or maritime questions, every country which is a member of the Organization—and there are more than 50 of them—is invited to send four delegates, two representing the Government, one representing organized employers and one representing organized workers. There is complete freedom of speech and voting for each of these groups of delegates, for the Organization is an entirely democratic institution. A few months before a Maritime Conference, there is usually a preparatory meeting on the same lines as the Conference but on a smaller scale, such a preparatory conference was held in November at Copenhagen. At these meetings experts from the chief maritime countries give their views on what improvements in standards are possible internationally at any given time.

What Is a Convention?

When the Conference decides on its international standards, they are put in writing in what is known as a Convention, which is a kind of international treaty. The Convention is then sent to Governments, which are obliged to submit it, within a definite time limit, to their parliament or congress or whatever body draws up the laws of the country. A decision is then taken by each country as to whether it will ratify the Convention—that is, whether it accepts the proposed treaty. If it does, it must see that its laws are brought into complete agreement with the standards set by the Convention. Machinery exists for making certain that countries carry out their obligations under any Convention they ratify.

The Conference decisions can also take the form of recommendations or resolutions, which are less formal and do not carry with them the same strict obligations for Governments. These forms of Conference action have, however, proved useful in the past in bringing before the world ideas and suggestions for improving working conditions, and in that way they have encouraged social progress.

Past Achievements

What has the ILO done so far for seamen? It has collected and published a lot of information on conditions of employment, such as wages, hours, insurance, and welfare in ports, in every country—information which is not usually available in collected form and which it is difficult for any one country or trade union to obtain for itself. This information is always at the disposal of Governments, shipowners' associations and seamen's unions.

In the second place, the Conventions so far adopted by the ILO cover a wide field of subjects which affect the daily life of seamen. They deal with such questions as hours of work, manning, facilities for finding employment, seamen's articles, the employment of young persons, officers' competency certificates, annual holidays with pay, sickness and unemployment insurance, shipowners' liability, and the repatriation of seamen. Together, these Conventions make up what has been called an International Seamen's Code. There are still gaps in the Code, however, and it will be for the Seattle Conference to fill some of them. There are already 15 Conventions on maritime employment and dock work, and on the average each of them has been accepted and applied by 17 States, including practically all the important shipping countries.

To quote only one example, the Convention on unemployment indemnity in case of shipwreck, which was passed in 1920 and has been accepted by nearly all the important maritime countries, provides for the payment of at least two months' wages to seamen when they lose their jobs because their ship is lost. This was agreed to at a time when no country had any laws granting such compensation—a striking instance of how the ILO can do good work for seamen and get the backing of maritime countries for its efforts.

Present Activities

The Conference in Copenhagen in November was organized by the ILO in preparation for the Seattle session. It brought together representatives of Governments, shipowners and seamen from 20 leading maritime countries for a preliminary consideration of a wide range of questions: wages, hours and manning on board ship; social security and pensions for seamen; crew accommodation; food standards and certificates for ships' cooks; certificates for able seamen; medical examination to protect seamen's health; holidays with pay; continuous employment; and the recognition of seamen's unions and the right of collective bargaining between shipowners' and seamen's organizations. The questions of wages, hours and manning were also considered but on this problem it proved difficult to reach satisfactory results, because the views of the shipowners and the seamen differed so widely. However, the discussion cleared the air, and it may be hoped that it will prove possible to find a firmer basis for an accord. On all the other questions substantial agreement was reached, and there is every reason to believe that Conventions which many countries can ratify will be adopted at the Seattle session.

Difficulties

No international agreement is easy of achievement. What are the difficulties in reaching agreement on ILO Conventions? The main one is that many delegates—whether Government, shipowners or seamen—want the standards laid down in a Convention to be exactly the same as—or better than—those in their own country. But such an attitude is contrary to the whole idea of the ILO which is to set up **international minimum** standards. Now, a minimum standard which can be accepted by most of the maritime countries is bound to fall considerably short of what exists in the most advanced countries. But does that make it useless? A delegate from a country with high standards in wages, accommodation, etc., may say: "What use is this Convention to me? You suggest a minimum wage of $60, $64 or perhaps $72 a month for an able seaman, but our seamen get more than that under their collective agreements. You say the minimum floor space for a man to sleep in should be 30 square feet in ships of 3,000 tons or over. But in the last ship I sailed in we had about 40 square feet. What interest can we have in these proposals or in making them into an International Convention?"

This is an old argument. An answer was recently given to it in a report on the Copenhagen Conference published in a French magazine produced by former members of the Resistance Movement in that country. It said: "The international measures proposed at Copenhagen will not bring many advantages to French seamen, whose conditions are in general more favorable than those in other counttries. But the proposals

are of interest to French seamen because they help to consolidate what we have already got. From the point of view of world social progress they will bring about a definite and often considerable improvement in the standard of living of seamen, particularly in the countries where conditions are very bad."

The value of international agreements was also emphasized by Admiral Land in 1944, when he said: "Can there be agreement among the maritime nations as to size, location and character of crews' quarters? If our standards in this respect are maintained and are so much higher than others, we are placed at a decided disadvantage in original cost and maintenance. If our standards are correct, how can we bring the other maritime nations into line? What part will the seamen's unions take in establishing uniformity? . . . The days when the dregs of the beach manned the ships are past, and we must have labor laws to meet present day conditions at sea. In so far as possible, there should be uniformity among the maritime nations in this regard."

An International Labor Convention is not intended to lay down exactly the highest standards that already exist in one or two countries. If it did, only very few countries would agree to it, and that would be of little value. The idea is to set up an international minimum, which may fall short of the standard of the best countries but is well ahead of the standard in the more backward countries. When the pressure of the unions or of public opinion, based on the ILO Convention, induces a majority of the maritime countries to accept that Convention, it means that the standards in the less advanced countries have to be brought up at least to the international minimum, and in many cases countries are willing to go a step or two further. From a humanitarian point of view this benefits the seamen in these countries, but it also benefits those in the more advanced countries because it means that the less advanced countries are no longer able to offer as severe competition in world shipping. Take again, for instance, the suggestion of $60, $64 or $72 a month as a minimum wage for an A.B. It may not help the seamen in the advanced countries directly, but what of the countries which, according to official figures collected by the ILO, are paying their seamen $44 a month? Isn't it worth while trying to bring them up to a higher international minimum?

It may be said from the seamen's side: "Yes, but if you fix a low international standard, then the shipowners of the advanced countries will try to deprive their seamen of their better conditions and pull them back to that lower minimum." This fear is groundless. In the first place, each Convention says that it is a minimum, and every country that accepts it solemnly promises that nothing in the Convention will be allowed to affect any higher standards that exist in any country. But there is a second and stronger argument against this fear of losing high standards. How were they obtained? Because collective bargaining was carried on in a reasonable spirit, and because the unions were strong enough to win concessions from the owners. If that is so, aren't these unions still strong enough to hold what they have won? Of course they are!

If, therefore, nothing can be lost through ILO Conventions and something can be gained by improved conditions in other countries, it obviously pays the workers in the advanced countries to back the Conventions even when they don't contain exactly what they would like to put into them. This is a point that people find difficult to grasp when they suddenly go to international meetings after fighting in their own collective negotiations for much higher standards. But it is the only sound basis for international progress in working conditions.

It is the hope of the ILO that the important questions on the agenda of the Seattle Conference will be tackled in this spirit with a view to improving the conditions of seamen everywhere and preventing unfair competition on the basis of inferior labor standards.

Competition for Freight Cargo

The Airlines Set a Fast Pace

Divested of all military trappings which it had used during service with the Air Transport Command, the first C-54 to be converted at the Martin plant into an air cargo carrier was delivered recently to American Air Lines. Above is the interior of the ship, complete with the necessary tie-downs, cargo lashes and other fittings. The ship stopped off at the new Newark, N. J., Airport and was viewed by thousands. A Martin passenger ramp was taken to Newark for the show and used by the sightseeing throng.

Flexibility in Small Shipyards

Commercial Iron Works, of Portland, Ore., will deliver to the U. S. Navy in April the aircraft carrier Rabaul. This is the last of the Navy ships under contract between the U. S. Navy and Commercial Iron Works and the last Navy ship to be constructed in the Port of Portland under World War II contracts.

The Rabaul will be the 200th ship delivered to the Navy by Commercial Iron Works and joins the ranks of other quality ships turned out in quantity by this company before, during and after the war. It's an impressive list — 200 ships; sixteen different types:

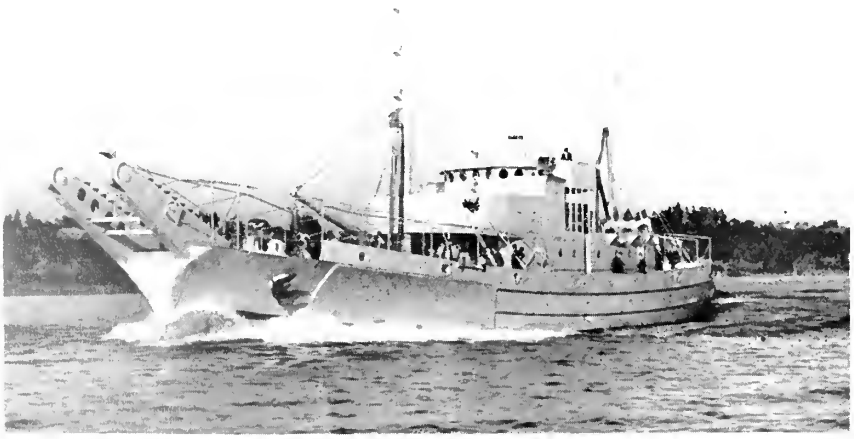
4 Net Tenders (YN)
7 Minesweepers (AM)
4 Fleet Tugs (AT)
41 Subchasers (PC)
2 Gun Boats (PGM)
6 Net Layers (AN)
56 Landing Craft, Infantry, Large [LCI(L)]
52 Landing Craft, Support, Large [LCS(L)]
12 Harbor Tugs (YTB)
4 Aircraft Carriers, Escort [AVG 6 class (CVE)]
3 Aircraft Carriers, Escort [CVE 105 class (CVE)]
3 Navy Attack Transports (APA)
1 Navy Troop Transport (AP)
2 Ammunition Tenders (AK)
2 Sludge Barges (YSR)
1 Oil Barge (YOS)

The smaller ships were built by Commercial Iron Works from the keel up, both on its ways and on the marine railway. The larger ships came as hulls for completion or as cargo ships for conversion; the conversions, in most cases, meaning practically a complete reconstruction job. On one job, the APA's, the yard acted as design agent in the conversion of cargo ships to attack transports.

Commercial Iron Works' ways can accommodate ships up to 250′ in length. The largest ships constructed there during the war were the AT class of Navy Fleet Tugs, 205′ x 38′ 6″ x 22′ 3″. The smaller ships, the YTB's, 100′ x 25′ x 13′ 6″, were built two to a way. When the company received its contract for building landing craft, the requirements of the war called for speed in production which brought into use the marine railway.

Above: An LCS-28 on trial run in the Willamette River.

Below: The USS "Catalpa." This was the first ship built under Navy contract in the Portland area since World War I. She was commissioned June 20, 1941.



Two Every Sunday

A design was worked out whereby four landing craft could be built on one special transfer track by extending the shunt cars to accommodate the extra length. Two ships were launched simultaneously every Sunday for the life of the contract. The ships were built stern to stern and, when launched, a sponsor would be at each end of the railway's cradle to strike the ships at the same time, the ships moving slowly down the incline to the water. It took about 30 minutes, the usual launching taking seconds. While these ships were being built on the railway, two ways were also devoted to landing craft, the other two ways being used on other ships under contract. The remaining transfer tracks were reserved for drydocking and were in constant use, ships coming from as far as Astoria for bottom work, installation of underwater gear, etc.

During the year 1944, Commercial Iron Works produced 112 ships, and reached a peak of 11 in one month, which was made possible through the added use of the marine railway for ship construction. If the Navy had never used the railway for repair it had still served a useful purpose and had been worth, many times over, the million and a half spent on it. These landing craft were used at Leyte, Saipan, Okinawa and other important landings leading to victory.

Since the end of the war, ships by

the hundred have been coming into the port of Portland for voyage repairs and for repairs and overhaul prior to storage at Tongue Point and Portland. Practically all of the small ships are handled on the marine railway at Commercial Iron Works. The largest ships handled were an LST and a Fletcher class destroyer.

The marine railway at this yard is something entirely different from the usual drydock. It was built on the sidehaul pattern to avoid difficulty in the handling of ships due to the rise and fall of the river. To lift a ship, keel blocks are prepared following the keel design of the ship. The cradle is then dropped into the river and the ship enters the cradle from the south end away from the outfitting dock. As the cradle starts up the incline, the blocks are pulled tight against the sides of the ship by means of hand winches on the catwalk of the cradle, assuring a firm setting. The time involved in a lift is as minutes compared to any other method of drydocking. As many as seven ships have been lifted, shunted, work accomplished and returned to the water in one day. These, of course, would be small ships, as a Fletcher class destroyer is left in the cradle for work while smaller ships can be shunted to transfer tracks.

The marine railway gives the port of Portland a special advantage in drydocking facilities for peace time. Small ships can be drydocked without the necessity of tieing up the port of Portland and Swan Island drydocks from large ships. The peace time use of Commercial Iron Works sludge barges, which clean ship's tanks by the "Wheeler Vacuum Process" is great. It allows tank cleaning without dirtying the ship to go on while handling cargo and can be done without delaying ships' schedules.

Commercial Iron Works, with the possible exception of the steel foundry, is a self-contained organization, and is a good example of flexibility in small yards.

Second from top: The USS "Salerno Bay" on trial run in the Columbia river.

Last two pictures: Two views of vessels being raised up the incline railway. Ross Island in the background.

Todd Handled 20,000 Ships

Rapid conversion of scores of peacetime vessels to war purposes, a program as critical in the first months after Pearl Harbor as repair and new construction, was a major project in the Atlantic, Gulf and Pacific Coast yards of Todd Shipyards Corporation, according to records revealed by the company.

The 127 ships converted by Todd yards totalled more than 1,330,000 deadweight tons. During the wartime period, Todd handled for repair and conversion more than 20,000 ships of some 108,000,000 tons. In addition Todd building yards completed 1,000 ships, a total of 6,000,000 tons, including airplane carriers, destroyers, submarine and destroyer tenders, Liberty ships and large landing craft.

As in war, Todd is in the forefront in the reconversion of ships to peacetime uses. The transport Argentina, first ship to be converted to carry G.I. brides and babies, was drydocked, redesigned and equipped at Todd Brooklyn, and she was followed immediately into dry dock by the Saturnia—which Todd previously had converted into the hospital ship Frances Y. Slanger.

The war stories of some of the famous ships handled by Todd yards are now recounted. Among the first ships which the company's yards sent into the Allied shipping pool after this country entered the war were the former French luxury liner Ile de France; the Furness-Bermuda liner Queen of Bermuda; the George Washington, 38-year-old former German liner, which was reclaimed from the scrap heap to become a first class troop transport under the hands of Todd workers; the United States liner America, which became the transport West Point, and the United States liner Manhattan, converted into the transport Wakefield.

The George Washington, of 23,788 gross tons, built in Stettin, Germany, in 1908, did transport duty in World War I after being seized by the Allies. She was converted back to passenger service after the end of that war, but after a few voyages was laid up.

When transports were desperately needed in the early part of World War II, the George Washington was hurriedly equipped as a troopship and pressed into service. However, with her existing boilers and coal-burning equipment, she was too slow even for sluggishly moving convoys.

The job of converting the vessel, whose hull, propulsion machinery and general design was pronounced worthy of the cost of conversion, was turned over to the Brooklyn division of Todd Shipyards Corporation on June 15, 1942. There the ship was changed from a coal to an oil-burner, the Scotch-type boilers were replaced by new water-tube boilers and numerous other auxiliary engine room units were installed.

The existing inadequate troop and crew berthing, messing, galley, sanitary, heating and ventilating systems were removed and replaced with modern equipment, and armament was placed aboard.

From a top speed of eleven knots, developed on trials after she was resurrected from the ship graveyard in the Patuxent River, off Solomon's Island, Md., the George Washington, after conversion to oil fuel at Todd's, achieved a loaded speed of 19 knots and a cruising radius of 15,000 miles—her oil capacity equalling that of a medium tanker. Accommodations were installed for 6,500 men, 480 officers and a crew of 240. The vessel was turned over to the Army transport service in mid-April, 1943. The job could have been completed in January of that year had the necessary materials been available.

Another notable conversion job accomplished by Todd, the Ile de France, was completed in 120 calendar days—from August 20, 1943, to December 18, 1943, eleven days fewer than the minimum estimated time. The vessel was equipped to carry 8,352 men, 1,354 officers and a crew of 626. This was more than double the troop-carrying capacity she had while operating as a hastily adapted troopship manned by an East Indian crew.

The Ile de France project necessitated the removal of inadequate trooping and crew facilities. These accommodations were completely redesigned and replaced with up-to-date equipment, including berthing, messing, kitchen and sanitary facilities. Many changes were made in the compartmentation of the vessel, and boilers, propelling units and all engine and boiler room auxiliaries were completely overhauled, as well as most of the deck machinery. Lighting and power wiring, to a considerable extent, were renewed throughout the vessel, as were interior communications. Life-saving equipment, including boats and handling gear, was completely overhauled and augmented.

In the spring of 1942, Todd was called upon to convert into a combat troopship the large, luxurious passenger liner Queen of Bermuda, well-known to thousands of pre-war travelers.

The Queen of Bermuda was a double problem for Todd shipworkers. Not only was the ship to be converted throughout, but she had been badly damaged from stern post to the forward part of her engine room. The ship's entire bottom had to be removed and reconstructed. All four propeller shafts were realigned, the drive motors were checked for alignment and all of the vessel's machinery and boilers were opened up and overhauled.

Then the Queen of Bermuda, which served as a commerce raider in the first years of the European war, virtually was rebuilt inside. Her handsome wood-paneling and wooden bulkheads were ripped out. Passenger salons, lounges, smoking rooms and "night club" were dismantled and partitions taken down. In their places were constructed troop berthing quarters, new ventilating systems, galleys, mess rooms and sanitary equipment. The job, begun April 4, 1942, was completed July 31, 1942.

One of the fastest and most extensive conversions ever performed on a big liner was accomplished at Todd Brooklyn division in changing into a permanent troop transport the West Point—formerly the America,

largest and fastest passenger liner ever built in the United States.

After our entry into the war, the 26,000-ton liner was hastily adapted for troop carrying, by means of the installation of additional bunks and temporary mess tables. However, as soon as practicable, the West Point was scheduled for complete overhauling, reconditioning and conversion as a permanent troopship, and she entered the Brooklyn yard on September 24, 1942.

The liner's fine wood stairs and paneling were removed and steel companion-ways and bulkheads substituted. Her turbine drive machinery was thoroughly overhauled. Hundreds more bunks were added and her spacious cabins and public rooms were transformed for the grim business of war. New ventilating systems, galleys, mess-halls and sanitary systems were installed.

Exactly thirty-one days after the work was begun, the West Point was ready to carry American fighting men overseas.

Other vessels serviced and repaired by Todd during the war include the Queen Mary and Queen Elizabeth; the diplomatic exchange ship Gripsholm, now scheduled to revert to the Swedish-American Line; the Washington (transport Mount Vernon), and the former Swedish-American liner Kungsholm, now the transport John Ericsson.

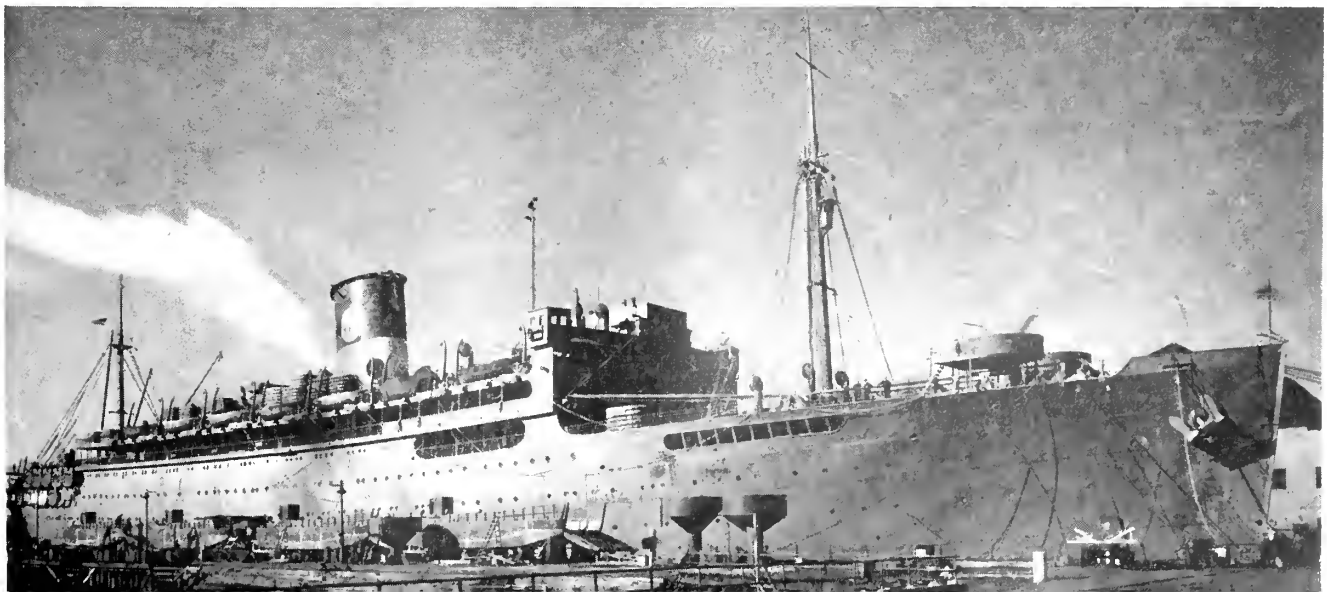
Another huge emergency conversion undertaking by Todd was the redesigning of 41 Victory ships into troop transports—22 of these vessels were converted in the Brooklyn yard and 19 in the Hoboken division. These 4,555-ton ships were enabled to accommodate 1,350 troops and 150 officers. Knockdown bunks were installed in the cargo spaces and the ships equipped and remodeled to carry cargo on the outbound trip and then, by setting up the demountable bunks, take troops on the trip back to the United States.

Todd also converted from C-4 hulls three of the Navy's newest hospital ships, the Haven, Benevolence and Sanctuary. Many types of ships for war service were converted in Todd yards, including attack transports, attack cargo ships, submarine tenders, auxiliary command headquarters ships, electronic repair ships, Army repair ships, aircraft transports, patrol frigates, store ships and others.

Of the total tonnage converted in Todd yards, the Brooklyn division handled 503,000 deadweight tons; Hoboken, 484,000; Galveston, 135,000; Todd-Johnson in New Orleans, 113,000, and Seattle, 95,000.

The Shipment of War Brides Presents Problems

G.I. brides and children will travel to the United States aboard the Army transport Argentina, which was converted at Todd Shipyards Corporation's Brooklyn Division to carry 550 war brides and babies. The Argentina was the first United States flag ship to be converted from troopship to bring Ameican soldiers' brides and children from overseas.



Industry's Stake In Our Merchant Marine

What is our policy on the new war-swollen fleet—shall we keep it, sell it, or junk it? Can we compete with low-cost foreign steamships? Here are advantages and handicaps to industry in "Shipping American."

The authoritative publication, "Modern Industry," recently published an excellent summarization of industry's stake in the American Merchant Marine, which the National Federation of American Shipping is anxious to have read by all who are interested in the future of the maritime industry. We publish it herewith through the courtesy of "Modern Industry."

The U. S. now has the largest merchant marine in the history of the world.

Will we keep it?

Should we keep it?

Is it important to industry?

These questions will be answered in the coming months and years by decisions of the Congress, Administration officials, shipowners, and the public.

England is working assiduously to regain supremacy of the seas. Norway, Greece, and other traditional maritime nations are planning comebacks. Russia, China, Brazil seek a slice of the world's shipping business. Even Switzerland has a merchant marine.

But today we have no definitely accepted, consistently followed maritime policy.

Our shipping men think our goal should be to carry about half our import and export trade in American bottoms. Our State Department and some top officials in other government agencies are against this. They believe foreign ships should carry our trade so foreign countries can earn more dollars to buy American goods.

The Navy wants to retain a big merchant fleet, both active and reserve, and a virile shipbuilding industry as a national defense measure.

The average citizen likes to see the Stars and Stripes flying from ships in every port, but wonders if it isn't an expensive luxury.

While industry wants to ship as cheaply as possible, it also wants efficient, dependable service that will open foreign markets and sources of raw materials.

In 1936 the Congress declared for a merchant marine sufficient to carry a substantial portion of our foreign trade and to provide service on all essential routes. For whatever it's worth, this is still our official policy.

Plenty of Cargo, but—

Our imports and exports are due for a big expansion in the next few years. This expansion probably will come whether the trade is carried in U. S. or foreign vessels.

Most foreigners make it almost a religion to ship and travel in vessels flying their flags. Americans have never done this.

Our 1936 Merchant Marine Act states that we should have a merchant fleet capable of carrying a "substantial portion" of our international commerce. Not since the Civil War have we carried as much as 50% of our foreign trade in our own ships.

In World War I and II we spent billions and sweat blood to build cargo fleets and transports. But between wars our ships rotted at anchor and our shipyards were virtually idle.

Obviously, a large merchant marine is a strong bulwark of national defense, worth considerable expense for this reason alone.

There are real advantages beyond pride and patriotism, however, in having American ships carry the goods of American manufacturers. Every ship line has agents here and abroad soliciting freight, drumming up trade, promoting imports and exports, encouraging passenger travel, finding new markets, assisting shippers in countless ways.

These representatives of American ship lines naturally will promote American trade.

American ships can give more direct and dependable service than foreign ships. For many years the only way American shippers could reach the East Coast of South America was in foreign ships via the European ports. This caused delays which severely handicapped them in competition with European firms. Even on the heavily traveled ship lanes, foreign vessels arrange schedules to suit the convenience of their own nationals

American ships employ American seamen, buy American supplies, seek repair in American ports. A single line, with four passenger and a dozen cargo ships, spent $30 million in a normal pre-war year for wages, supplies, maintenance, and repair.

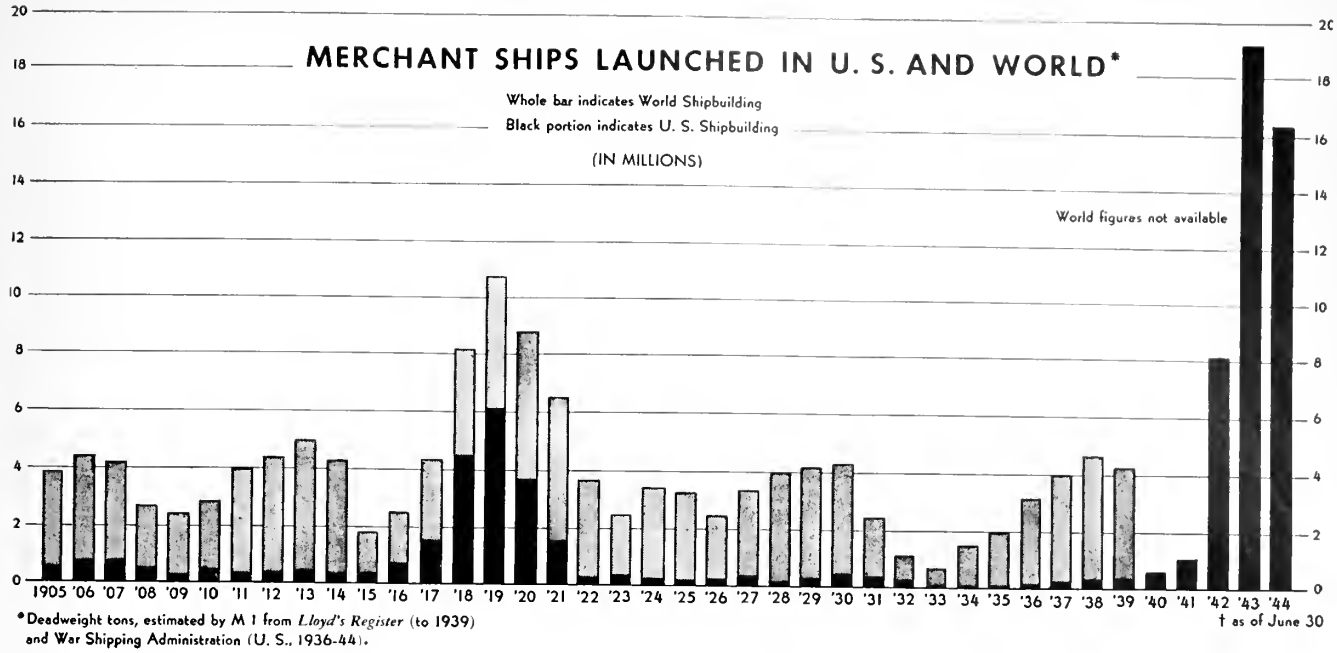
These ships buy virtually every type of American product, from light bulbs and bed sheets to cables and pumps. American shipyards, too, are big customers of American industry when they have ships to build and repair.

If it's a big merchant marine we want, why worry? We've got it. We have lots of ships, more than 5,000 of them, aggregating some 60 million deadweight (cargo capacity) tons—bigger than the pre-war fleets of Norway, Germany, and Japan combined. Two thirds of the world's merchant tonnage is American-owned.

World is Hungry for Ships

All other nations, with the possible exception of England, now have a shipping shortage.

But it takes more than ships to make a shipping line. It also requires



cargo and the ability to compete with other carriers.

Cargo to keep most of the world's shipping busy for a couple of years should be ample. But there is also plenty of competition, and more to come.

We had a big fleet after World War I; most of it, though, didn't stay on the seas long. Operating costs of U. S. lines have always been much higher than foreign lines because of our higher wage standards. Before the war wages of American seamen were 50% to 100% higher than foreign, and the spread is greater now. The same is true in ship repair yards.

This means that much of our shipping will have to have an operating subsidy—really a parity payment to American workers—if it is to stay in business.

Furthermore, much of our war-built shipping is not well suited to commercial use. Half our 5,000 new ships are Liberties, too slow to be economical on the average run. Most of our others were built for general cargo or war.

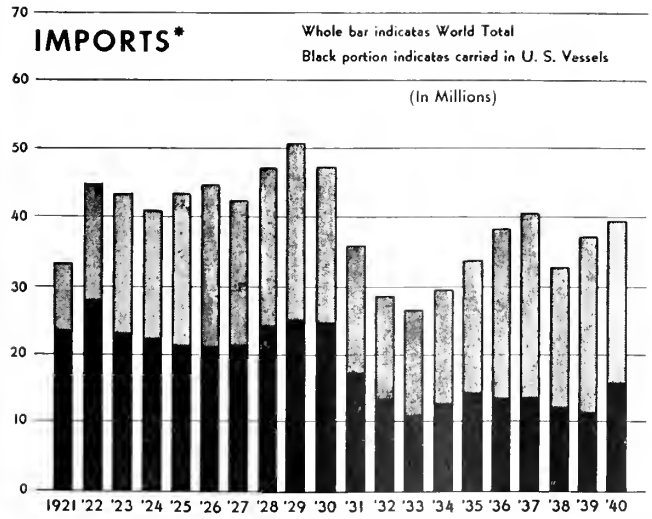
The most economical ship is one designed for certain cargo such as cattle, ore, fruit, or meat; with speed, size, and draft suitable to the oceans and harbors it is to ply; and equipped with the right type of hatches and booms. Foreign countries, while anxious to acquire some of our surplus ships, are all building or planning specialized, efficient ships.

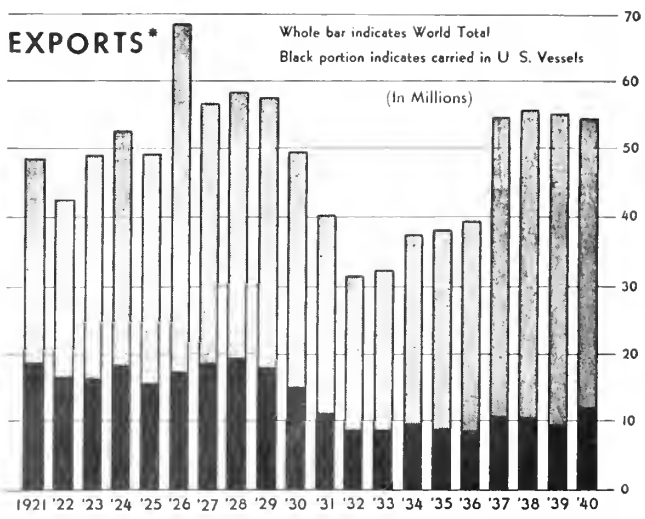
This competitive edge, plus lower foreign construction and operating wages, plus the obsession of foreigners to ship in their own vessels, adds up to stiff competition for American shipping lines a year or two from now, even though immediate prospects are fairly bright.

We can do several things to meet this rivalry. Of first importance are subsidies authorized by the 1936 Act to offset wage differential.

Subsidies vs. Freedom

Most American passenger and



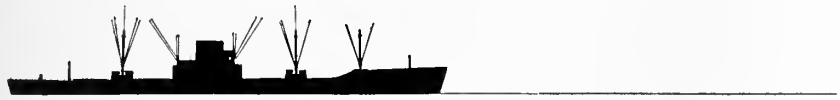


*In cargo tons of 2,240 lbs.—excluding cargoes carried by ships of less than 100 tons gross capacity.

S. S. *America*, passenger liner now Navy transport, has cruising radius of 12,100 miles; deadweight tonnage, 14,361. Propulsion, turbine.

Combination passenger and cargo type (C3 P & C). Length, 491 ft.; cruising radius, 20,300; deadweight tonnage, 9,937. Propulsion, turbine.

Combination passenger and cargo type for South American trade. Length 492 ft.; cruising radius, 18,600 miles; deadweight tonnage, 9,000.



Combination passenger and cargo type for routes between New York and South and East Africa. Length, 479 ft.; deadweight tonnage, 10,048.

Fast freight steamer for New York-Mediterranean and Indian trade. Length, 473 ft.; cruising radius, 15,600 miles; deadweight tonnage, 9,514.

Victory type for general cargo. Length, 455 ft.; cruising radius, 20,500 miles; deadweight tonnage, 10,850. Propulsion, turbine.

Liberty type (EC2-S-C1) for general cargoes. Length, 441 ft.; cruising radius, 9,000 miles. Propulsion, steam-reciprocating.

General cargo ship (C1-A). Length, 412 ft.; cruising radius, 18,900 miles; deadweight tonnage, 7,416. Propulsion, turbine or Diesel.

General cargo ship. Length, 459 ft.; cruising radius, 16,200 miles; deadweight tonnage, 8,514. Propulsion, turbine.

Tanker type (T2-SE-A1). Length, 523 ft.; estimated cruising radius, 12,600 miles; deadweight tonnage, 16,765. Propulsion, turbo-electric.

Transport type (P2-SE2-R1). Length, 608 ft.; deadweight tonnage, 12,063; shaft horsepower, 18,000. Propulsion, turbo-electric.

Far North Atlantic route (New York to Western Europe); accommodate about 1,200 passengers. Length, 745 ft.; cruising radius, 8,000 miles.

For service from New York to east coast of South America, which would reduce run between New York to Rio from 11 to 7-1/2 days. Length, 699 ft.

For New York to Mediterranean run provides for large cargo capacity, high speed, moderate size (650 ft.). Cruising radius, 12,500 miles.

For transpacific run out of San Francisco to China and Philippines provides tankage for the round trip of 14,500 miles. Length, 895 ft.

For San Froncisco to Australia run. Already operating for armed forces, would be reconverted, modernized. Calls for 4,000 tons of cargo.

many freight lines took these subsidies, which before the war amounted to about 50% of operating costs. With the subsidies go many restrictions. The vessels must maintain certain operating standards, keep to specified routes, maintain a definite sailing schedule whether or not they have full cargoes, submit their accounts for audit, and pay excess profits to the Maritime Commission.

On the basis of 1938 operations (the first full peacetime year of the subsidies) over a 10-year period this recapture provision, it was estimated, would pay back to the Government about two-thirds of the subsidy payments. This would suggest that American operators can compete, except perhaps in the luxury-passenger trade, if the Government takes part of the financial risk in building up new shipping routes and services.

Many American ship operators never applied for a subsidy, preferring freedom of operation to the rules and restrictions which accompany government aid.

Labor Costs Soared

On the other hand, labor costs have gone way up during the war. Seamen's wages, which averaged 50% above foreign before the war, have risen 77% since 1941; and maritime unions are talking about another 30% raise and a 40-hour work week.

Dockside costs are up 40% since 1941, and longshoremen's unions have imposed restrictions on man-hour output.

Repair, conversion, and maintenance costs are far above foreign shipyard charges. Ship operating subsidies may have to be far higher than before the war if our merchant marine is to remain large and vigorous.

Aside from its direct construction subsidy, the Maritime Commission has various trade-in, charter, and conversion provisions under which old vessels and war-built ships can be modernized and adapted to special services.

This program will give much work to many American shipyards. It will also give the right kinds of ships to meet foreign competition at investment costs not far out of line with anticipated foreign construction costs.

Domestic trade—coastwise, intercoastal, and with U. S. territories—has always been restricted to vessels of American registry, so no foreign competition exists here.

Before the war this trade occupied about 70% of U. S. shipping—some eight million deadweight tons of the 11 million tons of oceangoing vessels under the American flag.

Except for the territorial trade and coastwise tankers and colliers, this business has disappeared almost entirely. Ships taken by the Government for other service have been lost, converted, or worn out; hence substantial new investment is required for vessels adapted to this type of trade.

Railroads and trucks are now handling the freight. Coastal ship lines, which weren't very prosperous before the war, will have to institute major economies to lure that business back. Since 1940 the Interstate Commerce Commission has had jurisdiction over coastwise and intercoastal rates and routes.

ICC Rules the Roost

The ICC is under instructions from the Congress to maintain competition between all forms of transportation. It remains to be seen whether it will approve rates which will enable ship lines to attract business and make a profit.

Meanwhile the Maritime Commission, under temporary authority from the ICC, is resuming some intercoastal shipping services, employing private operators as its agents.

Early indications are that war-built ships are inefficient in this service. New or converted vessels might keep out of the red if their capital cost is not too high.

Under these conditions our war-built merchant fleet may be a white elephant. What to do with these ships poses tough problems.

The Government could sell them cheap to induce extensive use. But American lines would then be saddled with obsolete vessels, our shipyards would be idle, and foreigners would build for themselves efficient ships which would soon capture world trade.

This is exactly what happened after World War I, when we sold our "Hog Islanders" for whatever they would bring, which wasn't very much.

Higher Prices, Fewer Sales

Or the Government could put high prices on its ships to recover as much war cost as possible. If this happens, relatively few of our 5,000 ships would be sold, since operators would prefer to have new vessels built for more efficiency.

The new legislation provides that certain ships selected by the Navy and Maritime Commission are to be laid up "in sanctuary" and maintained as a reserve fleet for future emergency. To keep this fleet from hanging over the market as a threat to prices, no vessel can be taken out of sanctuary either for sale of charter without approval by the Congress. All surplus ships unsold or unchartered after two years are to be added to the sanctuary or scrapped.

The cost of maintaining these reserve ships in idleness will be considerable; and it is questionable how long the taxpayers will stand for it. Our whole merchant marine and surpus-ship program probably will be re-examined within a few years.

Many economists, including several in the Administration, think a big merchant marine either for use or as a defense reserve is a waste of money, a threat to other nations, an obstacle to international trade, and a continuance of an archaic kind of nationalism.

If foreign nations, with their lower construction and operating costs, they argue, are permitted to carry the world's trade all will benefit, trade will expand, and the ship-owning nations will be able to earn foreign exchange to buy more goods in the U. S. and elsewhere.

Good Balance for Foreigners

Answering this are figures showing how, in the 20 years between World War I and II, foreign countries derived a net favorable balance of about $40 million a year from goods and passengers in the U. S. seaborne trades—an amount equal to only 1% of the average value of our exports in the same period.

Even so, American shipowners argue there is no more reason for sacrificing our merchant marine to help foreigners get dollar exchange than to surrender an export industry for this purpose.

Last fall British shipyards had under construction 209 postwar-design merchant ships totaling 1,732,380 gross tons, and they plan a ship a day during 1946.

The Swedes, with expanded shipyard capacity, have orders for two or three years ahead. Danes, Norwegians, French, and Dutch are planning to rehabilitate their yards rapidly. They will build fast, specially adapted vessels, more economical to operate than our war-built ships,

Canal Barge Company's new Diesel towboat Codrington, built by Nashville Bridge Company and powered by General Motors.

Oil Barge Transportation on Ohio and Mississippi Rivers

Towboat "Codrington" Inaugurates New Service

FOR ABOUT FOUR years all classes of shipbuilding and shipping have been so controlled by the Government that new privately constructed and owned vessels of substantial size have been almost as "rare as hen's teeth." Consequently, it is of considerable interest to record the completion and shakedown runs of one of the first pre-war river transportation fleet developments. This consists of the new Diesel towboat "CODRINGTON" and integrated units or barges built under contract by the Nashville Bridge Company, Nashville, Tennessee, for the Cleveland Diesel Engine Division of the General Motors Corporation and acquired by the Canal Barge Company, New Orleans, La., for its oil-carrying service.

Although the trials of this fine modern craft were only run in January, she already is engaged in her regular duties on the Ohio and Mississippi Rivers where she has inaugurated a barge transportation movement on a route which is approximately a thousand miles each way.

Following preliminary builder's tests, the acceptance trials took place on January 10, and consisted of a 40 mile run down the Cumberland River pushing two 20,000 bbl. capacity steel oil barges to a point where the company officials were put ashore. The test took place without a hitch, and everyone aboard appeared to be fully satisfied with the performance. The towboat then proceeded on her way to her operating base to take aboard a load of crude oil for her maiden voyage to a distant refinery.

While transportation of petroleum by water is age old, there was comparatively little carrying of crude oil and refined products on the Mississippi River and its tributary waters prior to the early 1930's. With the development of proration legislation for oilfields, which limited well output; with the decline and fluctuation of prices, and with the imposition of heavy taxes and other restrictive petroleum laws, the cost of oil transportation became a serious problem to oil companies because of its effect on net profits. Naturally towboat reliability, economy and efficiency became very important factors in the transportation of oil by barge. The selection of types of towboat power, as well as the selection of particular makes of machinery were and are very important because of their direct bearing on efficient service and their relation to the commercial success of overall operating plans. The Canal Barge Company was one of the pioneers in the adoption of new methods and techniques for river towing, and also one of the first

to engage in hauling gasoline and other light oils on a contract transportation basis in the lower Mississippi territory.

Between 1930 and 1941 the U. S. Engineers embarked on a broad program of inland waterway improvement. Many existing rivers were improved and new canals opened to aid navigation and to assist in greater use of inland water transportation. Then followed the construction by the oil industry of necessary bulk terminals at strategic points capable of handling large quantities of crude and refined petroleum. As terminals were constructed for handling petroleum products along the inland waterways, facilities for the transportation thereof grew steadily. Formerly the method of towing barges owned by the oil companies was neither satisfactory nor very economical, especially as most of the motive power was steam. Barges would be dropped at terminals along the routes and then unloaded by whatever pumping facilities were available. Having no power of their own, the barges would remain there idle until another tug came along to tow them back to the starting points.

To overcome this situation, the Canal Barge Company undertook to organize and develop integrated transportation units consisting of specially built barges, specially developed tugs and towboats and likewise specially developed pumping facilities. The first step involved the design, development and construction of a barge that was specially suited for this type of operation and which would secure maximum efficiency not only through the speed with which it could be moved but also through the speed with which it could be unloaded so as to make it available for further operations.

This new barge embodied several innovations. It was a welded shell barge, whereas most barges then in use were either wooden or riveted steel. The bottoms were not flat but of a sort of V type with a six inch dead rise, which tended to deflect submerged logs and similar debris instead of permitting it to pass under the tow until it fouled the towboat propeller. This new type of bottom also made possible an internal construction that provided a well towards which the liquid contents of the barge gravitated so as to make possible a much more rapid and complete "stripping" or unloading of the barge. Thus the speed of movement, with the same power and fuel consumption, was increased.

In 1938 the General Motors Corporation collaborated with the Canal Barge Company, and designed a Diesel driven towboat which formed the prototype of the new vessel "CODRINGTON." Completed in 1939, she was named the "BULL CALF," and—it is interesting to mention—this vessel contained the first Air-Flex clutch-coupling and the experience and knowledge gained from her formed the basis for the Diesel engine plant of the war built LST's. The "BULL CALF" was smaller and had less power than the "CODRINGTON," being 88 ft. long and powered with a 750 HP G. M. Diesel engine, and her service performance has more than justified the larger and more powerful vessel being built along similar lines but capable of a much greater tonnage haul.

From the standpoint of river hauling the "CODRINGTON" is noteworthy. She is a fine example of postwar shipbuilding, and her power plant is a modern engineering achievement. Everything has been done to improve efficiency in conjunction with an increase in overall simplicity. It is only necessary to watch the captain handle the combined steering engine and propeller controls in the pilot house, and to note the instant response of the ship, in order to realize how much has been accomplished over the old steam stern wheeler. The total tow length, including the tug, is 591 ft., yet steering in the narrow river seems to be accomplished with the greatest of ease.

Named after George W. Codrington, Vice President, General Motors Corporation, who was responsible for the manufacture of the Diesel engines, this towboat is 110 ft. long, moulded, and 111 ft. 3 in. overall, with 26 ft. moulded beam; 26 ft. 9 in. maximum breadth, and 9 ft. 4 in. depth amidship. The sheer forward is 2 ft. 2 in. and aft it is 9 in. The hull and superstructure of the towboat is of all welded construction, and the steel fabricating workman-

The CODRINGTON pushing two 20,000-bbl. capacity steel barges during her acceptance trials on the Cumberland River.

ship and outfitting are of A-1 quality. Length of the two barges closely coupled together is 480 ft. To prevent up-and-down rubbing and wear where the two barges are connected, two 6½ in. pins fit into sockets, while heavy rubbing plates take the side thrust.

Propelling plant of the "CODRINGTON" consists of a 16-cylinder, Model 16-278A, General Motors Marine Diesel Engine of the two-cycle type rated to deliver 1,235 b. hp at 700 rpm, and this unit is coupled to an Air-Flex clutch and reversing mechanism and a reduction gear. This reversing unit has two constricting type air-operated clutches which provide flexible and resilient connection between the engine fly-wheel and the driving drums mounted at the forward, or engine end, of the gear unit. The rubber clutch glands are selectively inflated to obtain desired rotation of the propeller shaft. Under the arrangement of the air control it is impossible to inflate both clutches simultaneously. Reversing is accomplished through bevel pinions, and as astern and ahead reduction ratios are identical, full power and torque are available in both directions.

The main G. M. Diesel engine of the "CODRINGTON" is of V-design with port scavenging-air inlets and valve-in-the-head exhaust outlets. Scavenging is carried out by means of a blower mounted at the forward end of the engine which draws its air supply through a silencer and delivers it under low pressure to the combustion chambers. The blower consists of a pair of triple helical-lobed rotors in a closely fitting housing, but without actual metal-to-metal contact, and the design allows a continuous and uniform displacement of air. From the space between the inner and outer wall of the blower housing, the air passes into the air box around the cylinder liners, and into the cylinders when the pistons uncover the ports.

The crankcase is a one-piece fusion welded alloy steel structure of

Top: Part of the spacious accommodations provided for the officers on the CODRINGTON.

Center: One of the two-berth cabins.

Bottom: Pilot house. All instruments, gages and levers are mounted in a single unit for the convenience of the pilot.

great strength and stiffness, with the advantage of light weight. It is so designed that combustion loads are transmitted as straight tension from the upper deck plate of each cylinder bank through inclined side plates to the forged foot frames on which the main bearing supports are bolted. Steel plate stiffeners between the main frame members rigidly brace the frame structure.

The engine base also is of welded steel and firmly carries the crankcase, reverse reduction gear and Air-Flex clutch. The crankcase is a one-piece steel forging, drilled for lubricating oil passages, and statically and dynamically balanced. Pistons are of close grained alloy cast iron. The cylinder blocks are fitted with replaceable liners having integral water jackets. They also are made of cast iron and their bores are accurately honed to a mirror finish. The cooling spaces extend to below the scavenging air intake ports.

Supply of fuel is by a transfer pump on the engine which delivers the oil to the unit fuel-injection system, but the fuel passes through strainers arranged between the pump and the injector to ensure that no foreign matter reaches the spray nozzles. These strainers are easily cleaned or renewed. Surplus fuel is by-passed to ensure that any reverse flow of oil cannot carry dirt back into the injector when the engine is stopped.

The overall length of the engine is 16 ft. 9 in. from the aft coupling to the forward end, while the complete length of the entire power and reverse units is 25 ft. 9 in. The overall height from the crankshaft center is just over 6 ft., and the overall width is 5 ft. 9 in., making a very compact installation. Cooling is by means of a closed fresh water system.

The size of the propeller of the towboat is limited by her draft and by the size of the tunnel in which it turns. It is a three-bladed wheel of 82 in. diameter. At full speed the main engine rotates at 700 rpm and the propeller at 304 rpm. To increase the effective thrust and with a view to reducing any tendency for the tunnel and propeller to become clogged with driftwood, a special semi-nozzle has been installed in the after end of the tunnel. The latter is in the shape of a Venturi throat, being narrow at the after end. Rubber bearings carry the propeller shaft.

The entire engine room and its machinery has been white enamelled, which makes the compartment very bright. It is in charge of chief engineer Walter E. Andrews, with Leonard McDougal as second engineer and Tom Smith as third engineer. A clarifier takes care of cleaning the lubricating oil for the main engines, and the fuel oil for these engines is also filtered. For auxiliary power and electric light, there are two three-cylinder Model 3-71 General Motors Diesels, which drive 30-kw. direct current generators. The lubricating oil, as well as the fuel oil, for these auxiliary engines is filtered.

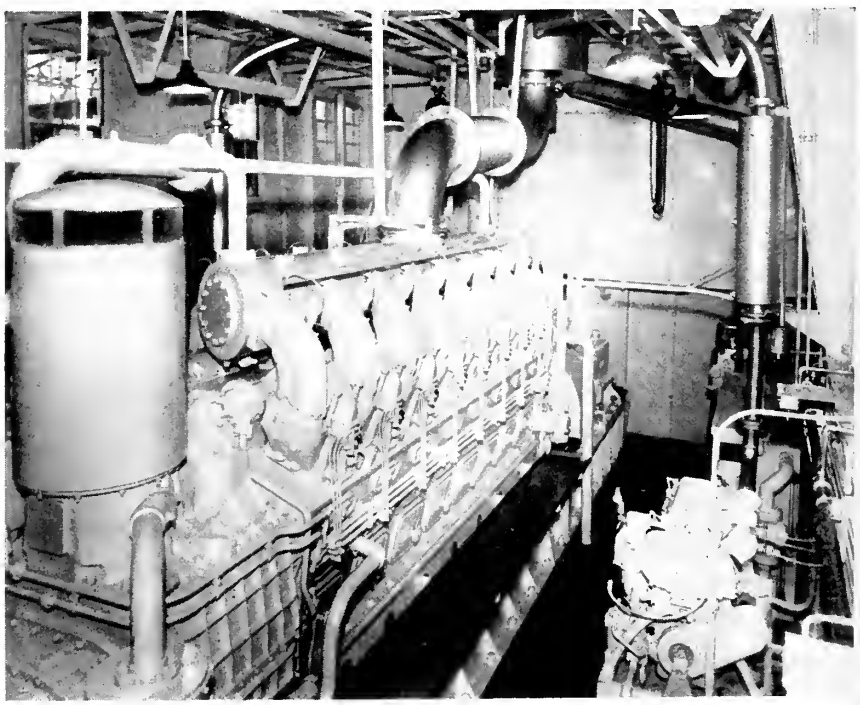
To heat the ship there is an oil-fired boiler which supplies hot water to the various radiators in the officers' and crews' quarters. Forward of the engine room there is a workshop equipped with sufficient tools to carry out minor repairs. In this space are located two air compressors, belt driven by the motors, and equipped with magnetic control. These units provide air for starting the Diesels and maneuvering them, as well as for the Air-Flex clutch and for the operation of the pilot house control gear and the rudder engine. There also is installed a bilge pump driven by a 15 hp electric motor.

In addition to the fuel tanks on the towboat, each of the barges carries a fuel-oil tank on deck, thus considerably increasing the cruising range without increasing the draft of the "CODRINGTON." Flexible piping is connected whenever the towboat's fuel tanks require replenishing. Also on the deck of each barge is a cargo-pumping unit consisting of a gasoline engine and deep-well pump. These units can be used for discharging cargo independently of shore equipment at any unloading point.

The pilot house control gear of the "CODRINGTON" was designed by Harry Dyer, President of the Nashville Bridge Company, and was manufactured and assembled at the shipyard. It is actuated by a 9 hp air motor, and, together with the various indicating instruments, is arranged in a single-unit stand or console, with the instruments and gauges mounted flush in its sloping top. All levers, including the twin rudder arms, are conveniently arranged in front of the pilot.

The forward part of the upper structure of the towboat below the pilot house houses the officers' accommodation and has a lounge or spare room. Aft of the lounge are two cabins with toilets and shower for the captain and pilot respectively.

The CODRINGTON'S main power plant—a 16-cylinder Model 16-278A General Motors Diesel, with clutch-reverse-reduction gear unit, is shown at the left. Auxiliary power is provided by the 3-cylinder Model 3-71 General Motors Diesel generator set in the right foreground.



These are spacious and well-furnished.

The engineers' and mates' quarters below those of the captain and pilot are also modern, insulated and heated. There are two two-berthed cabins with shower and toilet between them. Right aft is the combination galley and mess room. Food service is given directly from the hot tables, oil-fired range, etc., to a lunch counter, which facilitates service by the cook. Forward of the galley are the quarters for the cook and deck hands. On the deck above the galley is a riveted steel rowboat equipped to take an outboard motor, and handled by a derrick.

During the trial runs Captain R. R. Thorpe was at the controls. Present at the trial runs were the following representatives of the Cleveland Diesel Engine Division, General Motors Corporation; George W. Codrington, General Manager; Thomas E. Hughes, Sales Manager; Knut O. Keel, Chief Engineer; Benjamin H. Gommel, Commercial Sales Manager; John Kitco, Engineer; Theodore L. Meckbach, Manager, New York Office; Charles G. Gustavson, Engineer, New York Office; Dan Smith, Resident Engineer at Nashville and Trial Enginer; and C. L. Barnard, Manager, New Orleans Office. Also present were: Harry Dyer, President, Nashville Bridge Company; Harry B. Jordan, German Jordan and Joseph M. Jones, executives of the Canal Barge Company; Clark Berry, purchasing agent, Canal Barge Company; and R. B. Cook, consultating naval architect and member of Tams, Inc., New York.

Distinctive New Outboards

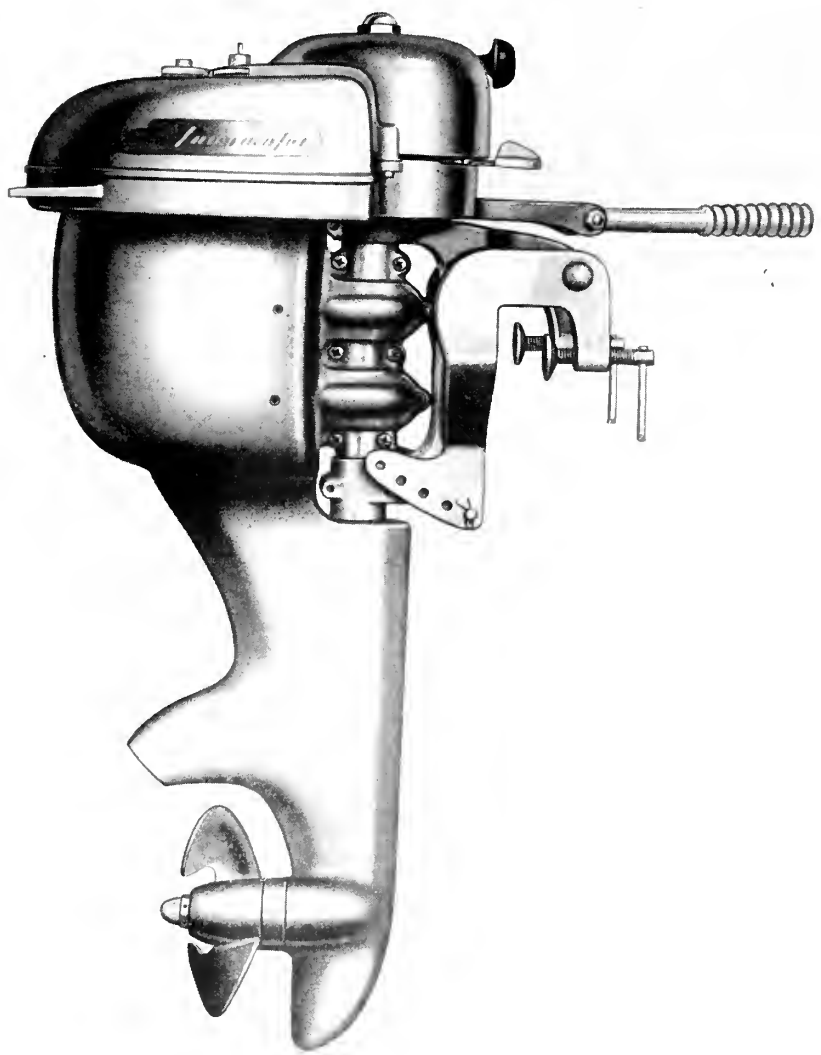
Timed with the New Year comes the announcement by Metal Products Corporation, Milwaukee, of its distinctive new line of outboards with marked advancements in design, construction and performance. With outboard motor users and dealers alike, the new outboards are sure to excite exceptional interest—as will the news that the line of three popular models, with piston displacements of 4.6, 9.2 and 15.9 cubic inches, in 2½, 5 and 10 horsepower, will be in quantity production and ready for deliveries to dealers by spring.

The officers of the corporation for years have been known in dealer circles and in the fields of motorboating and outboard racing. Its president and treasurer is George L. Kuehn, former motorboat racing champion with a long record of Wisconsin State, Central Divisional and National Championships. Louis Kuehn, his father and vice president of the corporation, is well known to hardware and building material dealers and jobbers from coast to coast, and long has been regarded as one of the nation's most esteemed industrial leaders through his long and successful record as founder and president of the Milwaukee Corrugating Company, later known as the Milcor Steel Company. Serving as vice president and chief engineer is Leo T. Kincannon, who ever since 1925 has been designing and testing engines, tools and machinery. His work on outboards has earned nationwide recognition, as he designed two previously successful, nationally known outboards. The secretary of the company is Edward H. Engelhorn, who has a long record of achievement with outstanding builders of engines. His 15 years of experience has established him as a leading figure in the manufacture of all types of outboard motors as well as in the field of racing outboards.

Features of the Metal Products Line

Outstanding among the features of

Outboard motor. Piston displacement 15.9 cubic inches.



Louis Kuehn, vice president, Metal Products Corp.

George L. Kuehn, president and treasurer, Metal Products Corp.

the new outboards is that they are 15% to 20% lighter and smaller than pre-war models of like horsepower. This is made possible by simplicity and a distinctively different type of design and construction—also the use of some of the new metals and alloys developed to meet wartime needs. The compactness of the trim, streamlined new models is immediately apparent. Not only does their smaller size and lighter weight make them easier to handle and carry, but hand grips are built in for extra convenience.

Quick, sure starting and smooth, even operation at all speeds, including trolling speed, are assured by a patented float-feed dual carburetion system with adjustments for high, intermediate and low speeds. Conveniently located controls provide remarkably easy, positive carburetor adjustments.

Shear-pin troubles have been eliminated through the utilization of a new patented propeller mechanism, which automatically disengages the propeller when it strikes an obstruction—and re-engages as soon as the propeller is again in the clear.

Another important design feature of the line, which sets a precedent in the outboard field, is that the new motors are entirely "outboard"—that is, no part of the motor extends inside the boat. This overcomes the problem of oil and gasoline dripping into the boat. The compact new outboards are set lower on the boat to provide better balance. Boats equipped with them are thus highly maneuverable—with full 180° steering. A special securing lock assures positive tilt-up position whenever desired. This does not depend on friction to maintain proper angle, but has a locking-pin which prevents the motor from slipping back to the normal operating position.

Edward H. Engelhorn (left), secretary, and Leo T. Kincannon, vice president and chief engineer, shown with new outboard.

Another outstanding design and construction innovation, the two-piece over-all motor housing, makes possible the removable cylinder sleeves and bearings. In case proper lubrication is neglected, thus causing damage to any bearings or cylinder sleeves, new ones can be inserted quickly, easily and economically. These new outboards have lightweight aluminum alloy pistons and connecting rods, hardened steel gears, hardened and ground bearing surfaces, counterbalanced crankshaft, automatic oiling, rotary neoprene water pump of a patented design, a collector-ring-equipped magneto that assures positive firing and eliminates broken and leaky wires resulting from constant flexing. Other distinctive advancements include the large capacity, die cast, streamlined gas tank, weedless type propeller, and underwater exhaust. All these combine to give the new outboards plenty of selling features to please any dealer—and provide dependable performance, maneuverability, and ease of handling and operation that is a pleasure to the most discriminating boat owner and user.

Pacific MARINE REVIEW

Washington Digest

Navigation and Inspection Law Waiver

The House has, without a record vote, passed the bill (H.R. 5716), to amend the Second War Powers Act, 1942, as amended, so as to continue certain features of the statute in effect until March 31, 1947. The bill had been favorably reported (H. Rept. 1714) to the House from the House Judiciary Committee by Representative Hobbs, Alabama.

Among the features of the Act which will be continued in force are emergency powers of the Interstate Commerce Commission over motor and water carriers, and provisions for the waiver of navigation and inspection laws.

The navigation and inspection law waiver is contained in Section 501 of the statute, which reads as follows:

"SEC. 501. The head of each department or agency responsible for the administration of the navigation and vessel inspection laws is directed to waive compliance with such laws upon the request of the Secretary of the Navy or the Secretary of War to the extent deemed necessary in the conduct of the war by the officer making the request. The head of such department or agency is authorized to waive compliance with such laws to such extent and in such manner and upon such terms as he may prescribe either upon his own initiative or upon the written recommendation of the head of any other Government agency whenever he deems that such action is necessary in the conduct of the war."

The bill now goes to the Senate for consideration.

Tonnage Allocated by WSA for Pacific Coast-Puerto Rico Service

Allocation of merchant ship tonnage to move cargo from Pacific Coast ports direct to Puerto Rico has been approved on a test basis, the War Shipping Administration has announced. Pope & Talbot, Inc., has been designated as berth agent to handle the direct shipment of cargo.

Prior to the war, intercoastal cargoes destined for Puerto Rico were carried on regular eastbound voyages by American-Hawaiian Steamship Company and Pope & Talbot, Inc. Since resumption of intercoastal operation, many ships have been operating eastbound at full capacity and the handling of Puerto Rico cargo on these voyages would conflict with this through traffic.

In approving the trial allocation of a monthly sailing to Puerto Rico, WSA approved allocation of other tonnage for future additional direct sailings to Pope & Talbot and American-Hawaiian Steamship Co., if the cargo conditions justify it.

Travel Groups Seek Removal of International Transport Barriers

Presentation of a united front to bring about greater freedom in international travel in the interest of world trade, peace and prosperity was the unanimous feeling of representatives of transportation and travel groups participating in a meeting at the Carlton Hotel. A committee of outstanding figures in the transportation world was formed to study the problem, outline a program for organization of the work for removal of unreasonable travel restrictions and to help promote world tourist and business travel. The committee is to report back to a second meeting of the group held March 27, 1946.

M. F. Redfern, secretary of the Air Transport Association of America, was appointed chairman of the committee and Almon Roth, president of National Federation of American Shipping, was named vice chairman. Other members are H. M. Paulsen, president, American Association of Travel Agents; Russell E. Singer, general manager, American Automobile association: Willard Givens, executive secretary, National Education Association, and Paul M. Hawkins, Washington representative, American Hotel Association.

The committee was instructed to survey any activities already in progress concerning revision of world travel barriers, including results of the survey in the March 27 report. Robert Ramspeck, executive vice president, Air Transport Association, was chairman of the meeting, and Col. Sidney Post Simpson, of New York Bar, was named counsel.

Modification of Transpacific Passenger Agreement Filed for M. C. Approval

Modification of the agreement of the Transpacific Passenger Conference (No. 131-201) so as to prohibit the appointment of freight brokers, forwarders or receivers of cargo, as agents, directly or indirectly, except as unanimously agreed upon by member companies, has been filed with the Maritime Commission for approval.

The modification was submitted and signed by the following conference members: American President Lines, Ltd; Canadian Australasian Line, Ltd.; Canadian Pacific Steamships, Ltd; Java Pacific Line (of the N. V. Stoomvaart Maatschappij "Nederland" and N. V. Rotterdamsche Lloyd); Silver Line, Ltd.; Klaveness Line; Matson Navigation Co.; Pacific Island Transport Line (A/S Thor Dahl); Prince Line, Ltd.; The Oceanic Steamship Co.; Trans-

atlantic Steamship Co., Ltd. (Rederiaktiebolaget Transatlantic), and Union Steam Ship Co. of New Zealand, Ltd.

Billing Procedure Is Outlined in WSA Accounting Instructions

Procedure to be followed by agents, general agents, and berth agents in billing for compensation pursuant to provisions of General Order No. 56 and preparing the statements required in connection with such billing has been outlined by the War Shipping Administration in Auditing and Accounting Instructions No. 51. Issued under date of March 1, 1946, over the signature of J. M. Quinn, comptroller, the instructions were made available March 14.

Government Set-Aside Food to Go to Ships of Approved Nations, WSA Says

Vessels of approved nations will be supplied food by Government-approved ship suppliers from Government set-aside orders the War Shipping Administration announces. Permission was granted for vessels of Greece, Netherlands, Norway, Sweden, United Kingdom, and tankers of Panama to stock food stores from WSA sources. Exemption from a previous order limiting supplies to U. S. ships was made possible by an agreement reached by the Department of Agriculture and the WSA.

The agreement followed an appeal by Ministries of Shipping of the six Nations to the Acting War Shipping Administrator for exemption and stating that it would be impossible for their vessels to obtain adequate quantities of food either in their home countries or through civilian channels in the United States. The exemption provides that foreign-flag vessels must comply with all other food control regulations and bulletins issued by the Food Control Division of WSA.

Other countries may be included in the exemption agreement if they make application to WSA including proof of inability to obtain food stores in their home countries and other qualifications.

All privately-owned ocean-going American flag vessels engaged in foreign commerce and coastwise vessels previously covered are included as authorized purchasers of Government controlled foodstuffs from approved ship suppliers.

Nielsen to Report to WSA On Foreign Seamen Wage Investigation

A comprehensive report based on intensive overseas studies of wages paid to seamen employed on foreign competing vessels will be presented to the War Shipping Administration shortly by Eric Nielsen, special assistant to the Deputy Administrator in charge of labor.

Mr. Nielsen has spent many weeks abroad, specifically to gather data on the subject of seamen wages for use at the forthcoming maritime conference to be held in Seattle the early part of June. However, it is also known that the Maritime Commission itself is interested in such a report for use in that agency, and for future reference as to adjustments of subsidies.

Friedlander Appointed as Consultant to Macauley

Appointment of Lt. Col. Joseph Friedlander in the capacity of consultant to Acting Chairman Edward Macauley, of the Maritime Commission, has been announced by Commission officials.

Col. Friedlander, who will assume his duties shortly, has been associated in the past with Dollar Steamship Lines, General Steamship Corporation, Swayne & Hoyt, American Trading Company, as well as having experience in tug and barge operations. During the course of the war he was employed by the Army Air Forces, handling overseas shipments for the Air Corps.

WSA States Bunker Fuel Shortage Is Delaying Relief Ships

Lack of bunker fuel oil has delayed the sailing of a number of critical vessels out-bound with vital cargoes of relief supplies, the War Shipping Administration states. Early March saw the complete depletion of all bunker fuel stocks in the Philadelphia area and the situation changed temporarily only because of the arrival of one tanker. At present New York is short of sufficient stocks, Norfolk is out, and additional ships will be delayed.

The shortage has hit the Gulf and Atlantic Coasts, WSA said, and although the situation on the Pacific Coast is not so critical, stocks of bunker fuel are far below normal levels.

There were ample tankers to meet transportation requirements and the shortage appeared to arise from heavy demand and a lack of production of bunker oil. No improvement is in sight unless positive corrective steps are taken, WSA said.

Two New Foreign Agreements Filed for Maritime Commission Approval

Establishment and maintenance of two additional joint steamship services are provided for in two conference agreements filed for approval of the Maritime Commission on March 5, 1946.

No. 7568—Between The Ocean Steam Ship Co. Ltd., The China Mutual Steam Navigation Co. Ltd., and the Nederlandsche Stoomvaart Maatschappij "Oceaan", provides for establishment of a joint service "in trades between United States ports on the one hand and foreign ports on the other". The exact trading area of this conference pact is not identified in the agreement, a situation, according to Maritime Commission of-

ficials, that may be questioned before approval of the agreement.

No. 7569—Between M/V Nonsuco, Inc. and S/S Vincente, Inc. (as one member or part only), covering establishment of a joint cargo service between United States ports and ports in the Far East including the ports of Japan, Korea, Formosa, Siberia, Manchuria, China, Indo-China and the Philippine Islands.

Both of the proposed agreements prohibit the pooling or other sharing of profits or losses as between the parties.

Over-Age Lakes Ships to Be Scrapped at Canadian Yard

Hulls of 29 over-age Great Lakes vessels, recently sold by the Maritime Commission to the By-Products Iron and Steel Corporation, Cleveland, Ohio, will be moved to Canada where they will be cut into scrap for remelting purposes, according to announcement by the Commission.

WSA Lists Passenger Fares Between U. S. and World-wide Areas

Passenger fares between United States ports and virtually all parts of the world for vessels operated for account of War Shipping Administration have been prescribed or reaffirmed by that agency in Rate Order No. 463, issued under date of March 7, 1946. The new Rate Order cancels the previously listed fares contained in Rate Order No. 222, which was issued late in 1943.

The new passenger fares are listed "in keeping with the gradual return to more normal standards of ocean passenger transportation," the Rate Order stated, but it was pointed out that as circumstances warrant the WSA hereafter will authorize special fares, etc., for application to vessels and lines operated for its account.

Fares Apply to or from All Ports

Between and	U. S. Pacific Coast Ports
Mexico—West Coast ports	$100.00
Guatemala, Salvador and Honduras—West Coast ports	120.00
Nicaragua and Costa Rica — West Coast ports	135.00
Panama and Panamal Canal Zone	150.00
Colombia—East Coast ports	175.00
Netherlands West Indies	190.00
Western Venezuela ports to and including Laguaira	190.00
Eastern Venezuela ports	200.00
Trinidad	200.00
Brazil—	
Natal and ports north therof	250.00
Ports south of Natal to and including Bahia	275.00
Ports south of Bahia to and including Santos	300.00
Ports south of Santos	325.00
Uruguay	350.00
Argentina—	
Mar del Plata and ports north thereof	350.00
Colombia	175.00
Ecuador	200.00

Ports south of Shanghai	275.00
Formosa	275.00
Philippine Islands	275.00
French Indo-China	300.00
Siam, Malay States, Sumatra and Java	325.00

Conditions Applicable to the Above Listed Fares:

Where accommodations of an emergency type are provided, such as "standee" or troop class berths, ordinary crew quarters, or when passengers are berthed in public room spaces, a discount of 33-1/3% may be granted, the resulting reduced fare if an uneven amount to be rounded off upward to the next unit of one dollar.

One child under 3 years of age in a family shall be free of charge, but any additional children under 3 years of age in the same family shall be charged quarter fares each. Children 3 years and under 12 years, half fare; 12 years and over, full fare.

United States and foreign government taxes, port dues, landing fees or other charges of every nature levied against passengers or passenger fares are not included in the above listed fares and shall be collected from or paid by passengers in addition to such fares.

All fares listed are on a "one-class" basis, with full public room promenade and other privileges, to the extent that vessel operating conditions permit and within the discretion of the Master of the vessel involved.

The assignment of accommodations, in view of the uniform fares herein provided, shall be made by vessel Agents at ports of embarkation, under direction and subject to the approval of the Representative of the War Shipping Administration for the area where practicable. Except where unusual circumstances prevent, preference in assignments shall be granted United States and foreign Diplomatic and Consular Officers, Military and Naval officers, and United States and foreign Government officials. On private civilian travel, preference shall be granted in relation to age, family considerations and other pertinent factors.

The fares are for through travel without change of vessel, and no forwarding, transshipment, or maintenance ashore shall be provided thereunder.

Through fares, between points or for routes not covered herein, and interport fares, will be quoted on application.

Orders Cancelled: Rate Order No. 222.

Admiralty Decisions

By Harold S. Dobbs
of the San Francisco Bar

Lighter Captain Not a Member of the Crew

In previous articles I have stressed the ambiguity that presently exists among the circuits in the matter of the classification of persons employed aboard barges and tugboats. In my last article I pointed out that in the **Dillon case,** 1945 A.M.C. 1486, Third Circuit, the court held that the libellant was a member of the crew and, therefore, not entitled to the benefits of the United States Compensation Act even though the employee's duties had no connection with the navigation of the vessel and the additional factor that the barge upon which he was employed had no motive power.

In the **Lindenberg case,** 1946 A. M.C. 46, Second Circuit, an appeal pressed the question of whether or not the district court was correct in affirming the Deputy Commissioner's decision that the claimant, a lighter captain, was not excluded from the coverage of the Longshoreman's and Harbor Workers' Compensation Act. It provides as an exception to Compensation coverage that masters and members of the crew of any vessel are expressly excluded.

The claimant in this case was a lighter captain by occupation and on June 6, 1944, the date of his injuries, was in the employ of the plaintiff as captain of its lighter Boonton which was afloat in the East River. The plaintiff's business is the lighterage of freight in and about New York Harbor by means of barges, lighters and gasoline hoisters, which are without power of self-propulsion and must be towed from place to place. The lighter Boonton, described also as a gasoline hoister, is a vessel of the barge type, 120 feet in length and 36½ feet in width, with a freight capacity of about 475 tons. It has a cabin 12 feet by 6, a mast and boom, and a gasoline engine used to load and unload drafts and to pump water from the hold. The claimant was employed at a daily wage for an eight hour day and at an hourly wage for overtime; he had no experience as a seaman and no master's or seaman's papers; was not furnished meals or quarters by his employer, and lived on shore, except on occasions when required to work overtime. His duties consisted of operating the engine to raise and lower drafts of freight, procuring bills of lading, checking each piece of freight as loaded and discharged, directing the stowing of the freight in order that it would be so placed as to facilitate its removal and to insure the vessel riding on an even keel, pumping out water from the hold, making minor repairs, throwing lines to the dock when tying up and affixing them to the lighter when casting off from the dock, tightening and loosening the lines from the lighter to the dock as occasion demanded, and watching the cargo when required overnight, for which extra duty he was paid overtime wages. At the time of his accident he was painting the cabin of the vessel and fell to the floor from a coal box on which he was standing. The Deputy Commissioner found the facts as stated above and they are amply supported by the testimony of the claimant, who was the only witness.

The appellant's objection is not to the foregoing findings but to the Commissioner's conclusion therefrom; namely, that the principal duties of the claimant were similar to those performed by longshoremen, checkers and talleymen in connection with the loading and discharging of cargo and were not principally in connection with the navigation of the vessel and that he was not a master or member of the crew of the lighter Boonton within the meaning of Section 3(a) (1) of the Act.

The contention is that **Norton** vs. **Warner Co.** (Rusin's Case) (321 U. S. 565, 1944 A.M.C. 337), requires the opposite conclusion. The court, however, did not agree. There the bargee was employed by the month and provided with quarters on board; he had no duties in connection with the handling of cargo and no shore duties; his duties in connection with navigation were more than pumping out and handling lines; they included responding to whistles from tugs and putting out navigation lights and signals. In the case at bar the claimant's primary duties had to do with the cargo and were such as longshoremen customarily perform. That he had the additional tasks of pumping the hold, handling the lines when docking or casting off, and making minor repairs, such as painting the cabin, is not enough to take him out of the class of harbor workers for whom the Act was intended to provide compensation. The court agreed with the Deputy Commissioner and the District Judge that the controlling authority is the **Bassett case,** 309 U. S. 251, 1940 A.M.C. 327.

As Chief Justice Hughes noted in the **Bassett case,** (309 U. S. at 259, 1940 A.M.C. 327), in construing the Longshoremen's and Harbor Workers' Compensation Act,

> "Little aid is to be found in considering the use of the term "crew" in other statutes having other purposes. Legislative intent may be defeated by giving an invariable definition to the same word in different statutes. Compare **United States** vs. **Monat,** 124 U. S. 303, with **United States** vs. **Hendee,** 124 U. S. 309 (the former that the paymaster's clerk was not an officer of the navy within the meaning of one statute and the latter holding he was an officer of the navy within the meaning of another statute). The case of **Long Island R. R. Co.** vs. **Lowe,** 1945 A. M. C. 143, 145 F. (2) 516 (2CCA) involved the question whether the employee's status as seaman or longshoreman should be determined by his duties on the day of the accident; it has nothing to do with the case at bar."

This case provides additional auth-

ority and proof that titles are unimportant and in each case one must carefully examine the duties of the particular employee and the circumstances under which they are carried out before coming to a conclusion that the employee is either a member of the crew and thereby excluded from the Act, or, on the other hand, is a longshoreman and harbor worker and entitled to the benefits of the Act.

Federal Employee May Sue Under "Suits In Admiralty" Act

The subject of this title has been a lively one in the Admiralty Courts during the last few years, due primarily to the fact that many federal employees have filed actions for damages as a result of personal injury under the Suits in Admiralty Act, even though in each case the employee was afforded protection under the United States Employees Compensation Act.

After a careful examination of the United States Employees Compensation Act, it will be discovered that it does not specifically provide that the relief set forth therein is exclusive.

The problem again arises in **Garland C. Marine** vs. **United States of America,** 1946, A.M.C. 53, United States District Court, where the libellant, employed as a customs inspector, filed a libel against the United States to recover for injuries sustained during the course of his official duties when he fell from an alleged defective ladder while leaving a merchant vessel owned by the United States. The vessel was berthed in Baltimore Harbor. Libel was filed under the Suits in Admiralty Act (Title 46 U.S.C. Sec. 742), which provides in effect that a libel in personam may be maintained against the United States where, if the vessel were privately owned and operated, suit could be maintained against the private owner. The United States excepted to the libel upon the ground that the libelant was an employee of the United States and therefore required to look for his sole remedy to the United States Compensation Act (5 U.S.C. Sec. 751-800). The court overruled the exceptions of the United States upon the ground that the compensation act does not expressly provide that the remedy set forth therein is exclusive of other remedies. The contention that the compensation act is the only remedy available to a libellant or plaintiff has been advanced in a number of cases where suits for personal injuries have been brought by a federal employee under other particular Acts of Congress. In such cases the sustainablity of the suit has depended almost uniformly upon the question of whether the particular Act afforded a basis for the suit. Otherwise stated the view was taken that the compensation act was not an exclusive remedy. But it has been frequently decided that if the plaintiff or libellant has accepted benefits under the compensation act, the suit for damages would thereby be barred.

In this case the suit is based upon the Suits in Admiralty Act. It contains no exception making the remedy unavailable to federal employees who otherwise come within its provisions. The respondent here contends that the exceptions should be implied because the libellant is a federal employee, and therefore the compensation act is the exclusive remedy. This contention is not sustainable from the decisions.

Brady vs. **Roosevelt S. S. Co.,** (317 U. S. 575, 1943 A.M.C. 1), while not strictly speaking a precise adjudication on the point, is, from the history of the litigation in the District Court and the Circuit Court of Appeals for the 2nd Circuit and the Supreme Court, so near to an expressed decision that it must be regarded as determinative here. In that case a United States Customs House Inspector was killed by a fall from a defective ladder used to board a vessel at a pier. At the time he was acting in the course of his official duties. The ship was owned by the United States Maritime Commission and was operated for it by the Roosevelt S. S. Company. His administratrix recovered a judgment against the latter in the District Court, which was reversed on appeal in the Second Circuit on the ground that the suit could only be maintained against the United States under the Suits in Admiralty Act. It will be noted that the facts in that case are almost identical with those in the instant case. In reversing the judgment of the Second Circuit the Supreme Court in an opinion by Justice Douglas said (317 U. S. page 577, 1943 A.M.C. page 3):

"And we may assume that petitioner could have sued either the United States or the Commission under the Suits in Admiralty Act. In any event, such a suit would be the exclusive remedy in Admiralty against either of them. **Eastern Transportation Co. vs. U. S.,** 272 U. S. 675, 1927 A.M.C. 174; **Emergency Fleet Corp.** vs. **Rosenberg Bros. & Co.,** 276 U. S. 202, 1928 A.M.C. 441. And it is likewise clear that the action in Admiralty afforded by Section 2 of the Suits in Admiralty Act is the available remedy against the United States or a corporation whose entire outstanding capital stock is owned by the United States or its representatives. **Johnson** vs. **Emergency Fleet Corp., supra.** The sole question here is whether the Suits in Admiralty Act makes private operators, such as respondent, non-suable for their torts."

And later in the opinion (317 U. S. page 581, 1943 A.M.C. p. 6) it was said:

> "Moreover, if, as apparently was the case here, the claimant was eligible to receive and did receive compensation under the United States Employees Compensation Act (39 Stat. 742, 5 U.S.C., sec. 751), he is barred from suing the United States for the tort. (**Dahn** v. **Davis,** 258 U. S. 421)."

Apart from the effect of the **Brady** case there seems to be no precise adjudication that a Government employee may maintain a suit under the Suits in Admiralty Act, but there are cases which either very clearly so imply or are closely analogous thereto. In the **George Washington,** (1929 A.M.C. 885, SDNY) it seems the maintainability of such a suit was virtually conceded although the libellant was barred by the prior acceptance of benefits under the compensation act. In **Matson Navigation Company** vs. **U. S.,** (284 U. S. 352 1932 A.M.C. 202), it was said in the opinion:

> "The language of such sec. 2 is general, embracing suits of maritime causes of action by owners, as well as by the third persons injured by the operation for the Government of merchant vessels."

In **Panama R. R.** vs. **Minnix,** (282 Fed. 47 5CCA), and **Panama R. R.** vs. **Strobel,** (282 Fed. 52 5CCA), it

General Engineering Looks Ahead

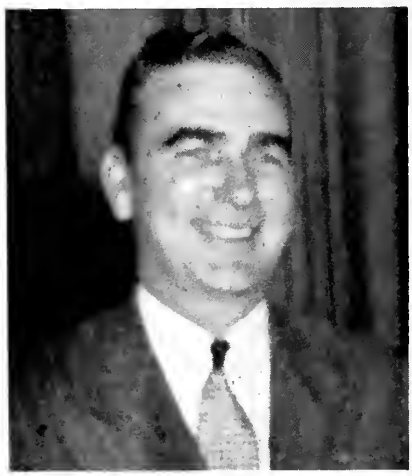
George A. Armes

In San Francisco announcement was made that the ownership of General Engineering and Dry Dock Corp. had been acquired by Godfrey K. Waters. Mr. Waters during recent years has been associated with the industry doing business with all of the major shipyards in the country.

The newly elected officers are W. L. Montgomery, President; Albert Wanner, Vice President; Frank H. Fox, Vice President and General Production Manager; and Peter P. Mesquita, Jr., Secretary - Treasurer. Mr. Waters, as Chairman of the Board, said that his interest in the future of the marine industry on the Pacific Coast prompted his decision to affiliate with the company and make his permanent residence in the Bay Area. The officers of the corporation have been with the firm for many years and no change will be effected in the directors of production.

For nearly twenty years prior to the recent war, General Engineering and Dry Dock Corp. engaged in the repair and construction of ships, barges, tugs and ferries in the San Francisco Bay Area. There will be no change in the policy of the firm and in the future they will continue to specialize in marine repair and conversion work. The men who directed their pre-war production activities, and who maintained an unusually high quality of work during the war, will continue to serve through the transition to peacetime operation.

W. L. Montgomery



Godfrey K. Waters

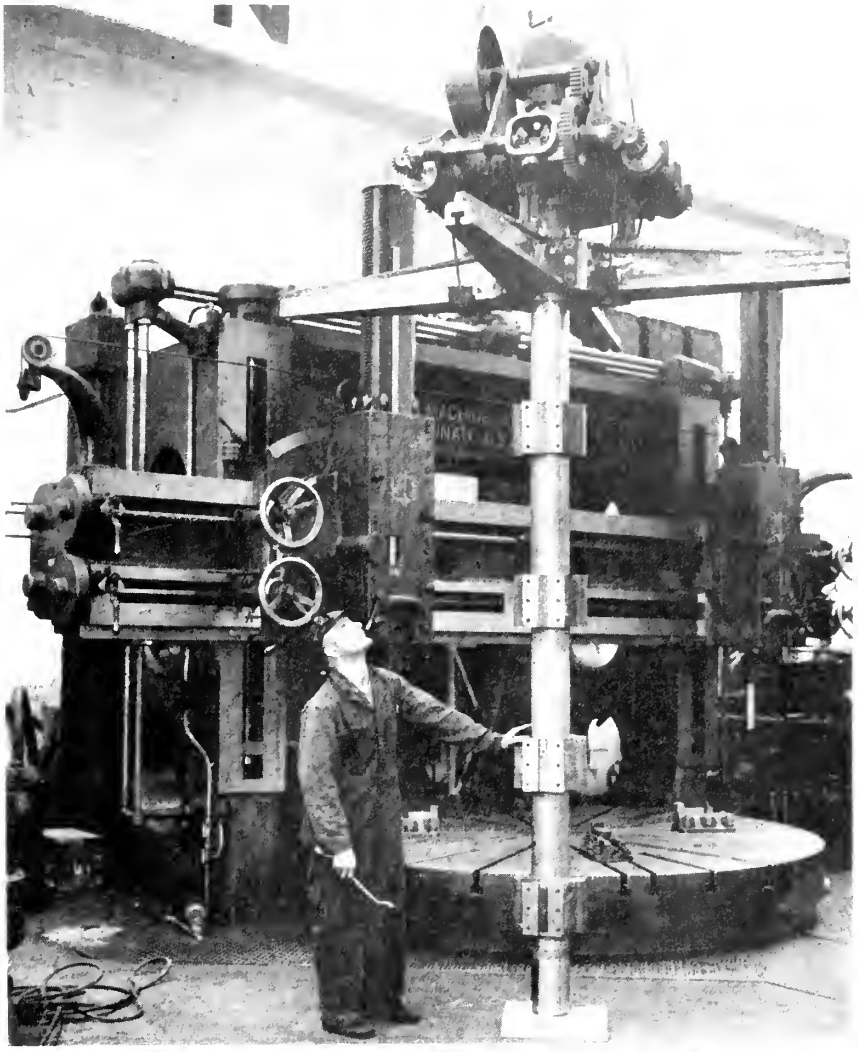
During the year following Pearl Harbor, GEDDCO increased its ship repair volume more than ten times, and for the past 2½ years has been delivering vessels—some of them requiring well over 100,000 man hours—at the rate of better than 17 a week. This work has been divided almost equally between the armed forces, government agencies, and commercial operators. For the Army and Navy up to June 30, 1945, they had repaired 1262 ships; for the W.S.A. and Maritime Commission, 1420; and for commercial operators, 1271 vessels.

Frank H. Fox, vice president and general production manager, has been

with the organization since its beginning in San Francisco and during the war received many official commendations for excellency of work and speed of production which came under his direction.

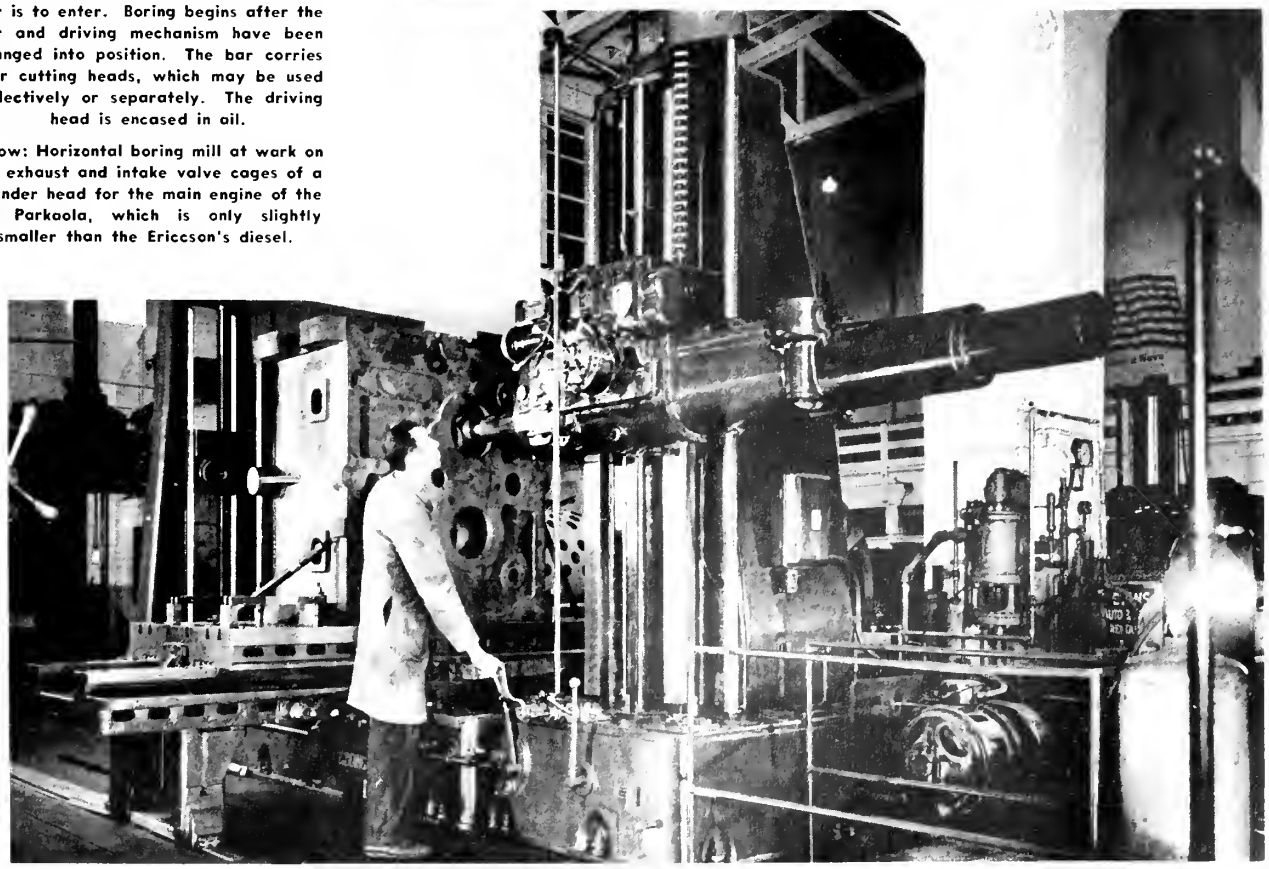
The Alameda yard of GEDDCO, located at the foot of Schiller Street, stretches for a half mile along the southern shore of the Estuary, opposite the Coast Guard base on Government Island. It is located at one of the widest points along the channel, providing ample room for launching vessels or maneuvering ships alongside the wharves, or into the dry dock or graving pits. All major shops are located near the wharves and docking facilities. It takes only a few minutes to move material from shop to ship, or for a man to walk from one end of the yard to the other.

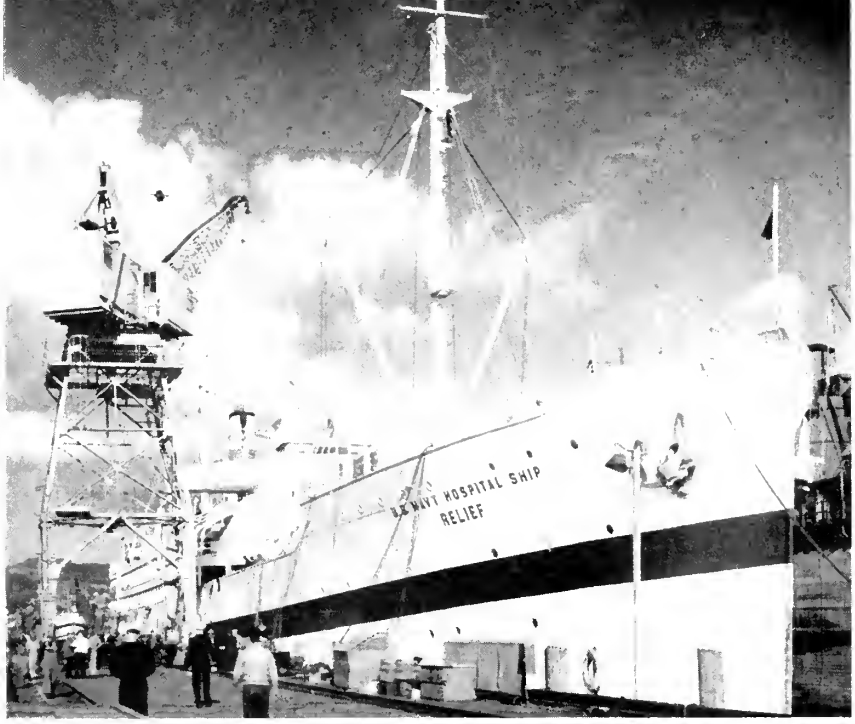
New construction work was concentrated in the western end of the



Above, right: Complete assembly of a special boring bar designed and constructed by GEDDCO for the U. S. Navy. Designed to bore the inside diameter of a submarine telescope mounting. A two-inch hole runs through the bar, with a cross-hair sight on either end. A sight is also placed across the work where the bor is to enter. Boring begins after the bar and driving mechanism have been changed into position. The bar corries four cutting heads, which may be used collectively or separately. The driving head is encased in oil.

Below: Horizontal boring mill at wark on the exhaust and intake valve cages of a cylinder head for the main engine of the MS Parkoola, which is only slightly smaller than the Ericcson's diesel.

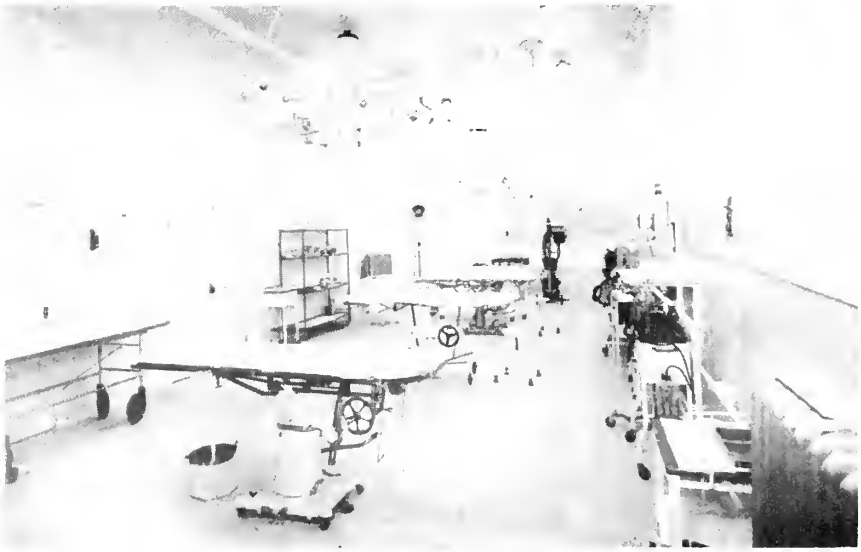




Frank H. Fox

yard, handy to the plate shop and the plate storage yard. The machine shop and rigging loft are close to the wharves and dry dock. The mill and joiner shop are immediately adjacent to the marine railways, and the administration building is located in the center of the yard. The warehouses are so placed that materials are right at hand as needed.

During the war the Alameda yard built the famous fleet minesweepers, and at the same time maintained a heavy schedule in repair and conversion work. A few of the more colorful conversion jobs included the



Top, left: The hospital ship Relief. One of the most memorable jobs turned out in the Alameda Yard was the up-dating of this, the Navy's oldest and for 20 years the country's only hospital ship.

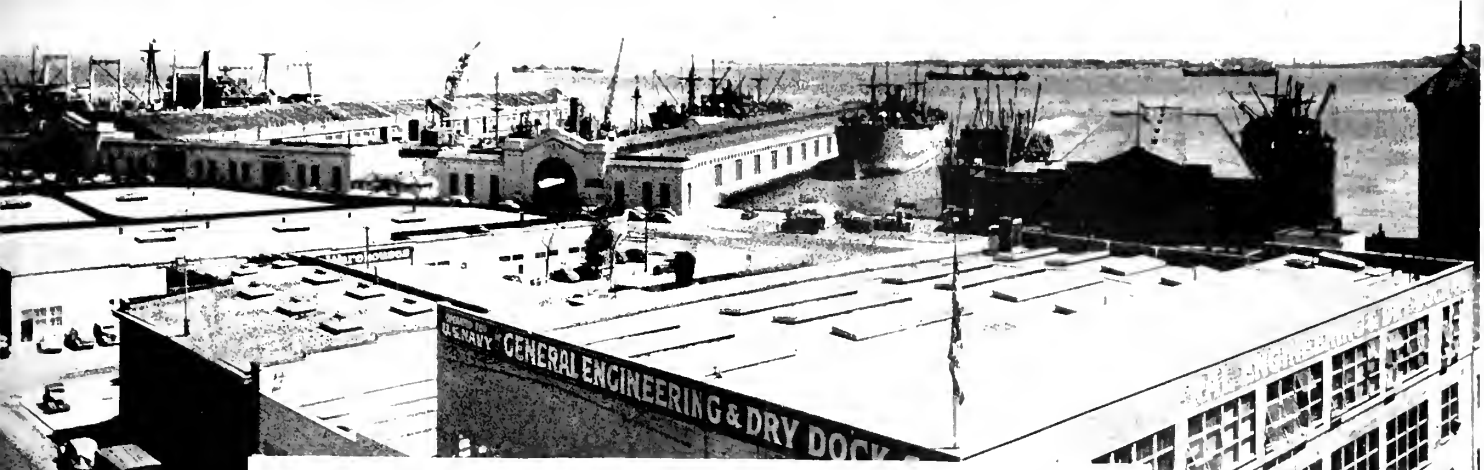
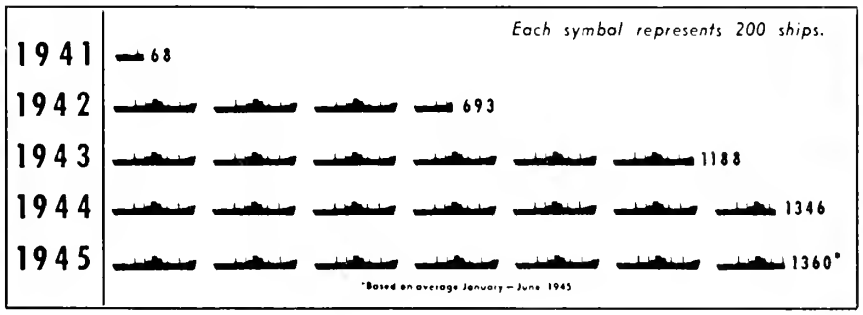
Bottom, left: Main operating room following modernization.

Peter P. Mesquita



Repairing 1300 Ships a Year

NUMBER OF VESSELS CONVERTED OR REPAIRED

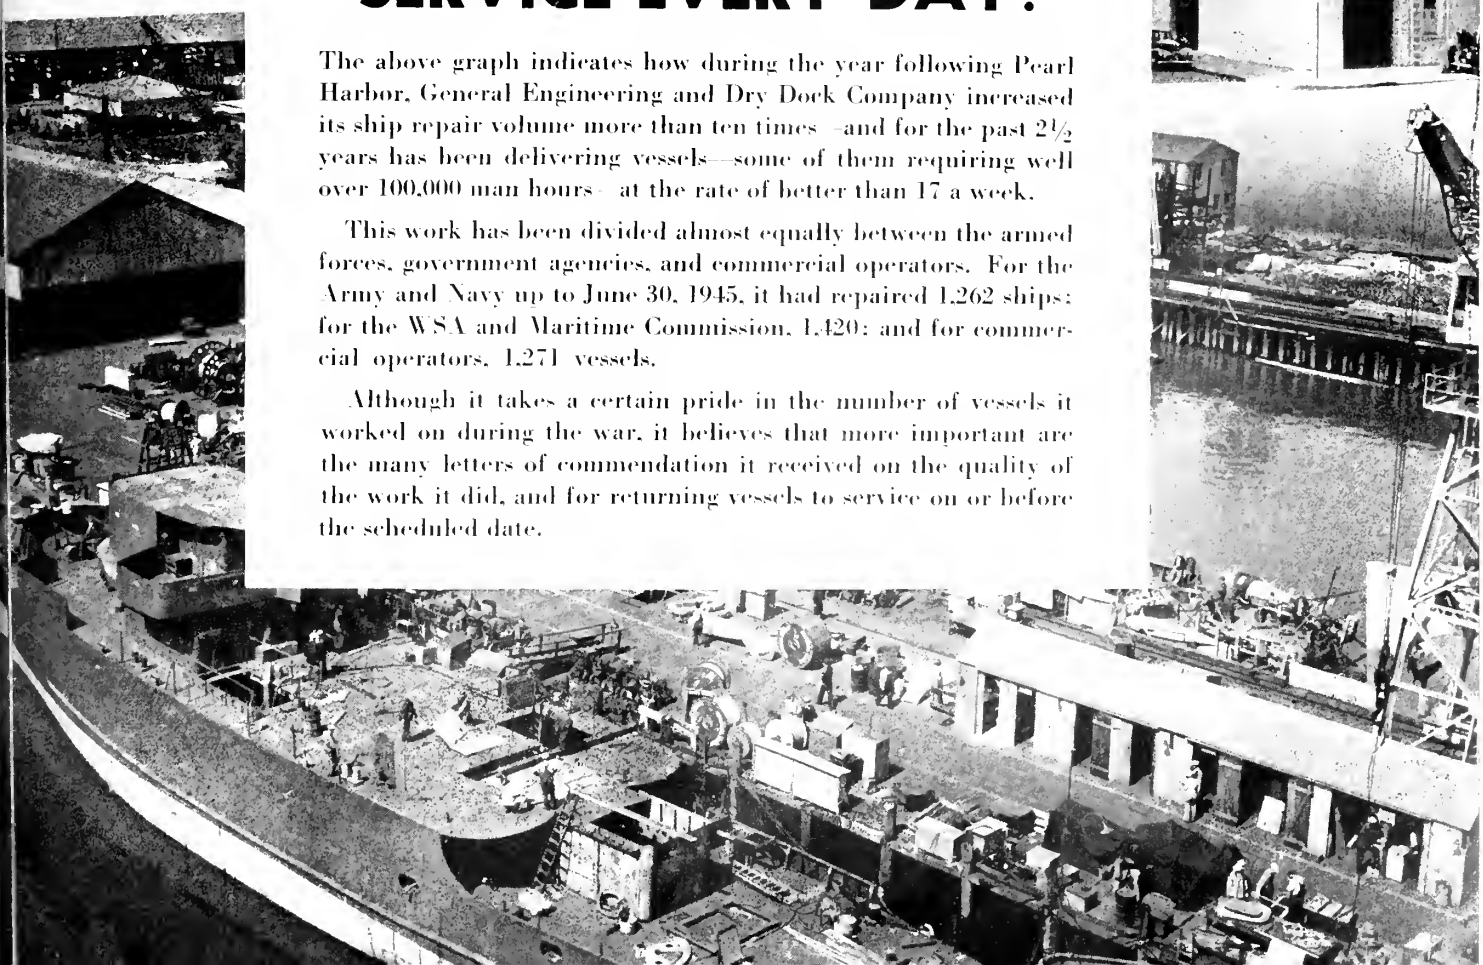


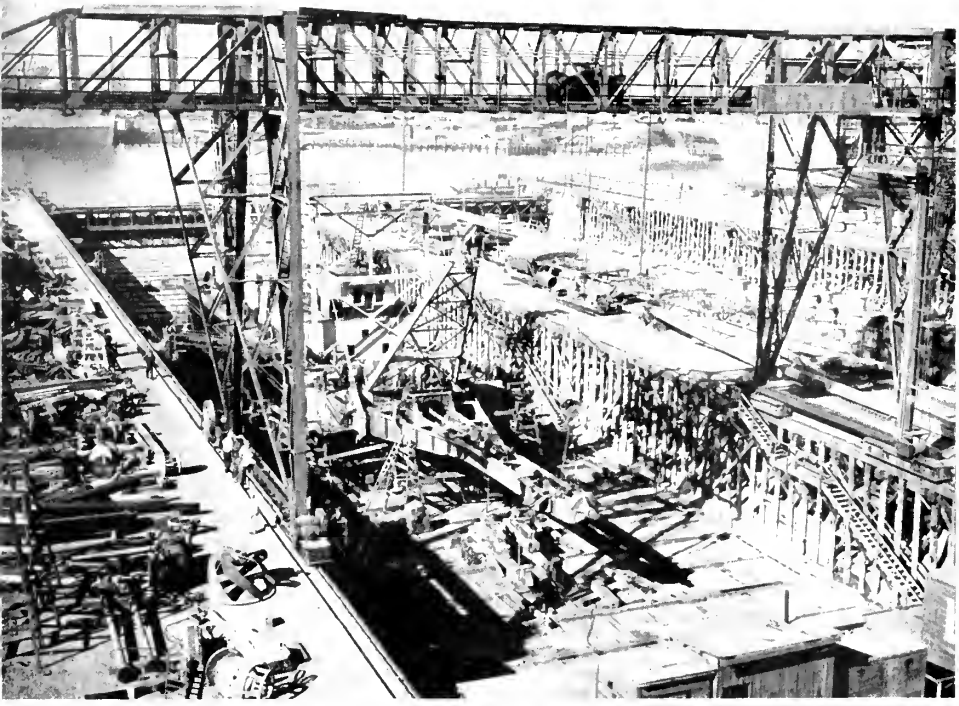
3.5 SHIPS RETURNED TO SERVICE EVERY DAY!

The above graph indicates how during the year following Pearl Harbor, General Engineering and Dry Dock Company increased its ship repair volume more than ten times—and for the past 2½ years has been delivering vessels—some of them requiring well over 100,000 man hours—at the rate of better than 17 a week.

This work has been divided almost equally between the armed forces, government agencies, and commercial operators. For the Army and Navy up to June 30, 1945, it had repaired 1,262 ships; for the WSA and Maritime Commission, 1,420; and for commercial operators, 1,271 vessels.

Although it takes a certain pride in the number of vessels it worked on during the war, it believes that more important are the many letters of commendation it received on the quality of the work it did, and for returning vessels to service on or before the scheduled date.





The dredge Golden Gate being completely reconditioned in one of three graving docks.

famed transport U.S.S. Henderson, which was converted into a Navy Hospital ship. Also the U.S.S. Pinkney which was the first of the A.P.H. Fleet to suffer from the use of the kamikaze plane.

GEDDCO shops in San Francisco are located adjacent to the waterfront adding much to their ability to render efficient service. Their main San Francisco offices are located at 1100 Sansome Street. This building includes Shop A. Shop A is devoted almost exclusively to marine repair work and includes a babbitting department, pipe shop, precision tool and die department. The babbitting department makes a specialty of cast

ing engine bearings, using the spin ning process. This department serve heavy machinery manufacturers i this area, as well as the marine in dustry.

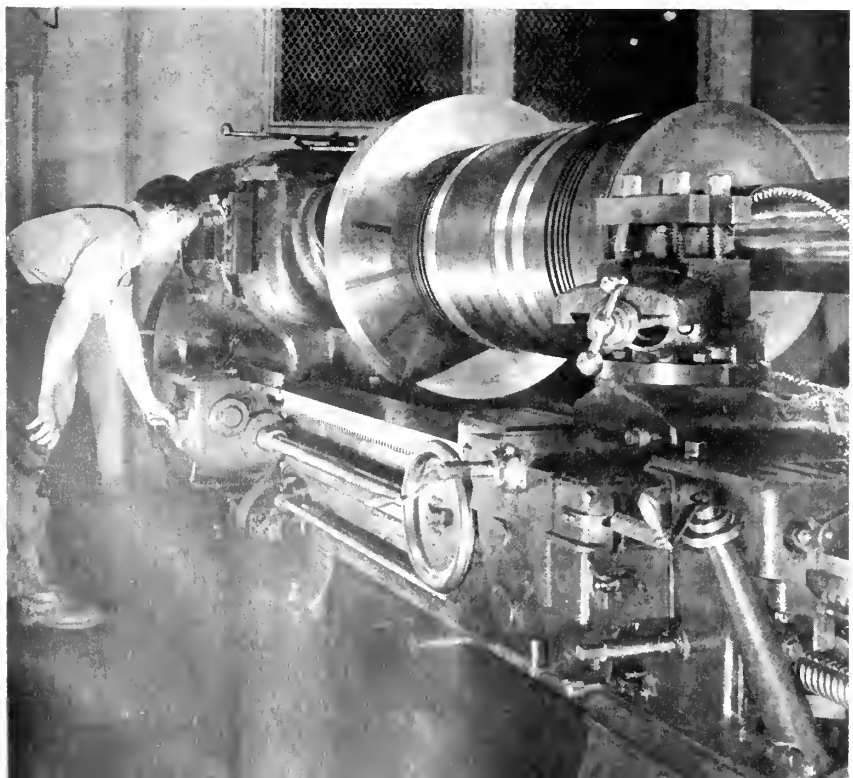
Shop B is located on Battery Stree and the buildings are adjacent t Shop A. These buildings include th blacksmith shop and a plate shop Machine Shop B is familiarly know as the "valve shop" since it has bee specializing in the repair and buildin of marine valves.

The newest GEDDCO plant wa completed early in 1943 and locate at Battery and Union Streets. Thes shops were outfitted with high spee machines needed for the repair o

A. P. Wanner

marine engines and auxiliary equip ment. These new buildings also in clude their carpenter shop, rigging loft and pattern shop. The machine shop has two overhead cranes, the largest of which has a capacity of 30 tons.

These facilities are near the com pany's waterfront facilities on Pier 25. Pier 25 is not just a center for despatching crews, but is a well equipped repair yard in itself. It contains a machine shop, sheetmetal and tin shop, plate shop, joiner shop, rigging loft, electrical drafting depart ment, welding, boiler repair, and



This water-cooled Niles lathe, shawn cutting a pistan rod fram a huge diesel engine assembly, has a 40-inch swing and can handle wark up to 21 feet between centers. This section of GEDDCO Shop C in San Francisco also is equipped with an American lathe with a 28-inch swing, 13 feet between centers.

electrical shops, and a large tool room. Gas and diesel engines from ships' boats are repaired in one section of the pier. As many as three ships can be handled at once at this 800-foot pier, which is located within two blocks of the San Francisco shops.

General Engineering's ability to repair vessels anywhere in the San Francisco Bay Area is one of the developments arising out of the necessity of recent years. Equipment and machinery fabricated in their shops is regularly moved by truck or barge, and installed aboard vessels at piers or anchorages.

The General Engineering and Dry Dock Corp. has recently published a beautiful 100-page illustrated book of their complete facilities. This book includes many pages in color and aerial views and may be obtained by directing requests to them at foot of Schiller Street, Alameda, California.

The Fond du Lac at Pier 25. Equipment and machinery fabricated in the San Francisco shops is regularly moved by truck or barge to variaus other jabs at piers or anchorages in the bay.

Vice Admiral Vickery's Work is Over

On the 21st of March Vice Admiral Howard L. Vickery, U. S. Navy retired, died very suddenly at Palm Springs, California. He had just arrived at the desert resort, with his wife, to take a much needed rest when a heart attack struck him and he passed away while being examined by the doctor. Interment, Arlington National Cemetery.

Howard L. Vickery was born in Bellevue, Ohio, in 1892 and was graduated from the U. S. Naval Academy, Annapolis, in 1915. He specialized in ship design and construction and throughout his Navy career was mainly attached to the Bureau of Construction and Repair. In 1937 he was loaned by the U. S. Navy to the U. S. Maritime Commission to organize the technical division of the Commission. Admiral Land immediately made Vickery his assistant in charge of ship design and construction in the program to rehabilitate the American Merchant Marine.

As result of Vickery's ability to inspire confidence and to transmit energy the Maritime Commission Technical Division was ready when the call came for emergency tonnage for war purposes and they amazed the maritime world with the speed of ship production in American shipyards.

Admiral Vickery drove toward the set construction goals with such inspired energy and such constructively critical contact that the goals were far surpassed and records in construction seldom lasted more than 30 days.

The result was a total of merchant tonnage which far outstripped the destruction of tonnage by the enemy submarines and air bombing, and which gave the U. S. Army and Navy, and our allies overseas, the supplies and munitions necessary to win the war.

If any one man deserves special credit for that result Vice Admiral Vickery was that man.

He wore out his heart putting that result across and laid down his life shortly after it was accomplished. This sacrifice of life, and there were many others like it, was just as surely a life lost in the service of his country as was that of any soldier or sailor by enemy action.

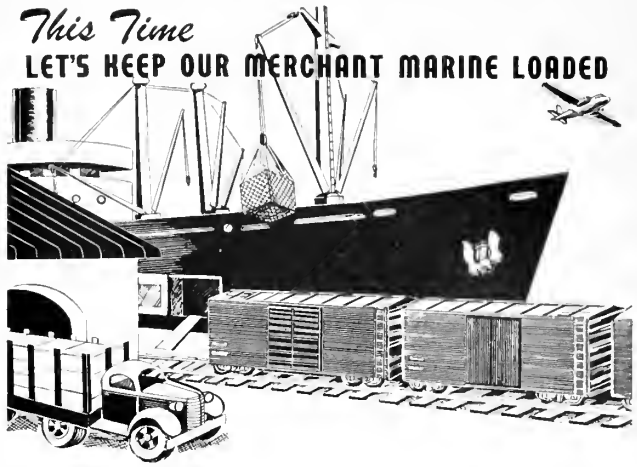
The accomplishments of Admiral Vickery won many national and international honors and decorations including: the U. S. Army Distinguished Service Medal; Knight Commander Military Division of the Order of the British Empire; Distinguished Service Certificate, American Legion; Officer Grand Dragon of Anam, French Indo-China; Victory Medal, World War I; and Morehead Medal, International Acetylene Association.

Among the qualities that were displayed in Admiral Vickery's contacts with shipbuilders were the rather rare abilities of prompt decision and of slashing through red tape. These two qualities were in no small measure responsible for the tremendous shipbuilding records made—records that put the citizens of United States under great obligation to this quiet forceful naval officer who got things done in a great hurry and done well.

Vice Admiral Vickery is survived by Mrs. Vickery and by two children, Lt. Comdr. Hugh B. Vickery, U.S.N., and Miss Barbara Willia Vickery.

Pacific WORLD TRADE
Reg. U. S. Pat. Off.

By T. Douglas MacMullen



Our Shipping Policy and Foreign Trade

By George R. Paschal

For many years, some foreign shipping interests have sought to talk the United States out of an adequate merchant marine on the ground that shipping is unimportant to us but crucial to other nations. The matter of our national defense and of shipping's vital role therein has been hurriedly passed over in such propaganda, since no one can dispute our need for vessels for defense purposes or contest the fact that twice in a generation we have come close to losing wars through lack of enough ships and the trained crews to man them.

Twice we have had to improvise vast shipbuilding programs in frantic haste with an accompanying waste of billions of dollars due to failure to maintain a proper merchant marine ready for any emergency. Twice we have seen our armies waiting uselessly at home for lack of vessels to move them, and have had two wars drag out for many unnecessary months—the last one at a cost of some $250,000,000 per day. Even a few days cut from the length of the war through our having had an adequate merchant marine would have meant a saving of many times as much as would have been spent in building or maintaining the proper tonnage.

In addition, three times within a generation we have seen foreign vessels withdrawn in good part from our trades to serve emergency needs at home.* As a result, our commerce has been disrupted and in some cases we have been forced to pay exorbitant rates to such foreign tonnage as remained. That disruption was far less in 1939 than in 1914. and the rates charged our shippers were far lower, solely because we had a merchant marine in 1939—inadequate though it was— as against an even weaker fleet with almost no ships in foreign trade prior to World War I.

But it is not the function or desire of foreign shipping interests to discuss America's maritime needs from an impartial standpoint. The usual presentation passes over the question of national defense with brief mention, and instead dwells at great length and with great inaccuracy on the alleged "fact" that earnings of foreign shipping pay for "an important part" of our exports. The "conclusion" is then drawn that if we should operate in post-war years a much larger merchant marine than the one found inadequate for our safety in 1941, it would be only at the cost of much of our exports and our prosperity, and of the prosperity or even stability of other maritime nations.

It is thus sought to "prove" that the reversion of our merchant marine to its state of pre-war inadequacy (which Admiral King has warned against) will really be to our own advantage, and will bring about true international cooperation. As we see it, this kind of cooperating means that we should be content to do the "cooing" while the foreigners do the "operating."

The Facts of the Case

In an effort to ascertain the facts regarding the effect of shipping on American export trade as affected by the international balance of payments, THE GRACE LOG examined the matter, and published (March 1944 issue) an analysis of the balance of payments statistics compiled by the Department of Commerce itself.** These statistics showed that

*During two wars, and the British coal strike in 1926.

In 1943 the Department of Commerce published a comprehensive report entitled **The United States in the World Economy which was designed to describe, factually, the relationship of the economy of the United States to that of other nations and the world at large. It was a distinct contribution to knowledge. Table I, among the accompanying exhibits, showed the balance of international payments of the United States. This revealed for each year from 1919 to 1938 inclusive the net balance resulting from the exchange of goods and services between the United States and the remainder of the world.

World Trade Makes Jobs!

during the twenty years of peace (1919-38) between the two world wars—when foreign shipping was predominant in our trade—the actual net foreign shipping earnings available for buying American exports amounted on the average to less than $35,000,000 annually, or less than one per cent of the average value of our exports in that period. (Naturally, since the one per cent figure is an average, the percentage in individual years was in some cases higher, in some lower.)

Our own computations for the sample year 1937 (a time of exceptionally large foreign ship earnings), also showed that if the United States then had operated a substantially larger merchant fleet—one assumed to carry even as much as sixty per cent of our foreign trade—this could have no appreciable adverse effect on our prosperity. If operation of such a fleet had equalized more or less the revenues derived by American and foreign shipping, and thereby had wiped out the net balance of foreign earnings, the theoretical loss of exports brought about by this would have been counterbalanced by a roughly equivalent increase in domestic employment and sales.

In addition, it has been pointed out by Admiral Land, as Chairman of the Maritime Commission, that if American foreign trade in the postwar years grows to the extent estimated by the Department of Commerce, the American merchant marine can be increased to a size adequate for our defense without reducing the gross dollar earnings of friendly foreign nations. American shipping can take the place in our trades of former Axis lines without hurting our Allies, and can also carry a substantial part of the prospective increase in our exports and imports. This carriage of new traffic need not interfere with the retention by Allied shipping of its pre-war trade.

Furthermore, far from attempting to drive friendly shipping from the seas, or to operate even a major part of our war-built fleet, Congress is favorably considering the sale of surplus ships to foreigners on the same financial terms as to Americans.

These facts, which have demolished the foreign "economic" case and the "American aggression" spectre, are well known to most foreign shipping interests but not to our own public in general, and hence the attacks continue. Some of the attacks, even on reasonable American shipping expansion, seem to be motivated by a desire to exclude the United States even from the carriage of our fair share of the prospective postwar increase in our foreign trade which the Department of Commerce now forecasts. Thus, we are told that we ought not to operate much more tonnage than we did in 1939, although our overseas trade is expected to double.

Department of Commerce Studies

For many years, no one effectively challenged and reduced to its proper proportions the foreign contention that shipping in foreign trade is unimportant to us, but is vitally necessary to other maritime nations. As a result some of our present-day economists and officials, not yet aware of the full facts of the case, have continued to debate whether we should, or should not, have a larger merchant fleet in foreign trade—this despite the fact that Congress itself long since has crossed that bridge after very full weighing of the pros and cons. The only result has been, not to reverse legislatively-declared American shipping policy, but rather to contribute to vacillation in its carrying out in peacetime.

Meanwhile, by its studies, the Department of Commerce has thrown light on the contention of foreign interests that their shipping earns much of Europe's daily bread. In addition to the facts brought out by the balance of payments statistics, cited above, it also has been shown (in a table published in the April 29, 1944 Foreign Commerce Weekly, and reproduced herewith) that the ratio between income from shipping and national income of the principal maritime countries has been extremely low for all except Norway, the only country where the figure exceeded 2.5 per cent. (Britain, in fact, derived only 1.3 per cent of its national income from shipping operations in the sample year 1937.) Figures for employment in shipping operations afloat have been proportionately even lower—with Norway the only nation to have over one per cent of its labor force so occupied.

These two Department of Commerce studies, and the implications which can fairly be drawn from them, have come as quite a blow to the foreign propagandists and have served as eye-openers to the public here. They seem to establish that shipping is a minor earning factor both at home and abroad, and that actual net earnings of foreign shipping do little to promote sales of American exports.

But, as cogently pointed out by the British shipping magazine Fairplay, the percentage which net shipping income bears to total national income (which we believe conclusive as to the argument that certain countries "live by their shipping earnings") does not necessarily have anything to do with the relation between such earnings and the imports of the nations concerned.

To examine this latter relation, we must determine, first, what percentage of the various countries' total imports is paid for by their net foreign exchange earnings from shipping; and second (which is much more relevant to the problem at hand), what percentage of their imports is paid for by net ship earnings in United States trade. Since we do not generally offer competition on routes aside from those to and from our country, expansion of our merchant marine can hardly affect foreign earnings obtained elsewhere.

The answer seems to be that for Norway, Greece and a few other countries, net foreign exchange earned from shipping is of real importance in the purchase of imports. For other nations, such as the United Kingdom, shipping earnings, while less important in percentage terms, are still to be reckoned with. The reckoning for most countries, however, is obscured by a tendency to confuse gross earnings, or some modification thereof, with net balance of payments figures.

But except in the case of Norway, which had about 40 per cent of its shipping in United States trades, only minor fractions of the various major foreign merchant marines serve our commerce. The British, for example, had about 10 per cent of their vessels so employed. Thus, for all but Norway, net earnings which might be affected by our competition cover only a small fraction of the foreign exchange needed by the respective countries. In fact, even a substantial reduction in net earnings accruing to foreign shipping in the United States trade would not have any material effect on the imports or prosperity of any foreign country except Norway—and her ships in our trades are mainly tankers, tramps, or special types, having

little prospective American competition.

Now, however, some of the staff of the Department of Commerce do not like the conclusions drawn logically—and, we believe, accurately—from its own figures; and seek to escape their implications. In the September 22, 1945 issue of Foreign Commerce Weekly published by the Department of Commerce, appears an article entitled "Shipping Policy and the Balance of Payments" by John H. Smith,—also the author of "World Income From Shipping" printed in the April 29, 1944 issue of the same publication. This most recent article seeks to demonstrate that shipping earnings are, after all, of large importance to certain foreign countries for the purchase of our goods, and that if we increase the American merchant marine in any notable degree it can be done only at the cost of a substantial fall in our exports. Yet the author cannot deny that the basic statistics—which have been presented in clear fashion in previous publications by the Department of Commerce—show that we can become a greater maritime nation without real economic disadvantage.

Analysis Based on Monopoly Assumption

The article in question attributes to unnamed persons the contention that if American vessels carried all of our goods this would reduce foreign purchases of our exports only one per cent. We know of no one who has suggested that American vessels should monopolize the carriage of our trade; or that "the net shipping balance would merely disappear (become zero) if the United States carried all its own trade." But on the basis of this peculiar assertion the Department of Commerce article builds up a towering structure of theory by assuming an American shipping monopoly of our trade. It attempts to show that if we had carried every pound of our imports and exports in the 1919-39 period, foreign earnings of dollar exchange would have been reduced enough to decrease our exports by 5.3 per cent. To support such a figure, the idea is then developed that the measure of the shipping earnings available to foreign nations for purchase of our exports is not that given in the Commerce Department's own balance of payments data—which lists what the foreigners actually earned from shipping as compared with our earnings, the difference then being the foreign balance to be spent for our goods. Instead, the article asserts that the measure of that figure should be actual net foreign shipping earnings in our trades plus "savings" equivalent to sums those shippers might have lost if we had monopolized all carriage! Finally, the article states that this over-all 5.3 per cent reduction in purchasing power would have fallen primarily on a few nations such as Norway, Netherlands and Greece; and then it seeks to demonstrate that these three countries in the past have depended on shipping earnings for the dollars to pay for about half of their imports from the United States.

In arriving at these "conclusions," and hence leaving the implication that the United States should not operate a larger merchant fleet in the post-war years, the author has employed statistics and techniques which we believe are open to serious question. The true facts seem to present a different picture and yield a contrary conclusion. Yet since the matters dealt with are complex and technical, some readers—unfamiliar with the whole problem and the data employed—may be misled (by the apparent authority of the mass of statistics presented) into accepting the author's premises and "figures" as valid, and his implied conclusions as a statement of sound policy.

To repeat, no responsible American officials or shipping men have proposed, or desire, that American ships monopolize carriage of our foreign trade. The highest figure which has been seriously advanced is that we should operate enough vessels, and of sufficiently high quality, to earn and merit the carriage, on the average, of about half of our foreign trade—more in some trades, less in others. *** Elementary reasoning would suggest, and careful analysis will substantiate, that if we had done this in the inter-war years, the balance of payments on shipping account (i. e., roughly "what we earn from foreigners" versus "what foreigners earn from us," but not the gross earnings of foreign ships) would have been reduced to somewhere near zero; and as a result the reduction in net foreign earnings would have been equivalent to about one per cent of the average value of our 1919-38 pre-war exports, and to no other figure.

Unreal Assumption

Yet by pyramiding, on top of actual net earnings, theoretical losses from a theoretical monopoly which never existed, and is not now and never has been advocated, Mr. Smith's article magnifies the importance of available foreign shipping earnings many fold. And worst of all, that study, even though it begins by treating the magnified total as a merely theoretical one, good only if a monopoly is sought, ends by accepting this inflated percentage as a measure of actual fact. And it is so quoted by Fairplay, an influential foreign shipping magazine.

The inflated figure, however, is not applicable. It is only a shadow produced by placing an untenable hypothesis between the light of reason and a blank piece of paper. Naturally, if American vessels carried all of our trade instead of the half the Maritime Commission proposes as a reasonable aspiration, then foreign countries would have to pay us for shipping services rendered them on our exports, and the balance of payments would be against foreign countries. But to imply that this theoretical figure has any bearing on shipping policy demonstrates a disappointing lack of logic on the author's part. The point of practical economic analysis is to find clues which can serve as guides in evaluating or proposing future policy. We determine what the actual situation has been. We calculate what the effect of a proposed change in policy would have been if it had been made under past conditions. Useful results can be obtained only if the hypothetical model conforms to realistic proposals in hand.

To summarize, if American shipping, in the years 1919-38, had carried roughly half of our foreign commerce and passenger trade, foreign countries (including the Axis) would have suffered a reduction in net dollar earnings equivalent in value on the average to about one per cent of our exports—this cannot be successfully disputed. That reduction would not have affected our domestic prosperity in any measurable degree—it would have been equivalent to less than seventy cents on every thousand dollars of United States annual national income. Fur-

***According to Maritime Commission estimates this would involve operation of about 15,000,000 deadweight tons (including coastal and intercoastal trades, etc.), in contrast to the some 60,000,000 we had at the wartime peak.

thermore it would have been compensated for by a roughly offsetting increase in domestic sales brought about by greater employment in American shipping and shipbuilding.

Effect of Reduction on Foreign Nations

As regards the effect of the reduction on foreign nations, it might have decreased principally the dollar earnings of the British, Norwegians, Germans and Japanese. The Japanese and Germans we can demiss. British earnings in our trade are, by Department of Commerce data, insignificant in comparison with British total balance of payment figures, and furthermore are derived mainly from passenger carriage—a field with only moderate prospective American competition. This leaves Norway as the only country in which a reduction in earnings in American trade might have had any material effect; and such a possible effect is minimized by the fact that Norwegian vessels are of types not likely to be in serious competion with American ships. Furthermore, on the average, Norway sells us more than she buys from us, and hence does not need ship earnings to buy U. S. goods.

In commenting on the most recent Department of Commerce article, we have refrained from discussing in detail the statistical computations given therein, the economic reasoning employed, or the trade data marshalled in support. But it must be said for the information of the reader that the "net earnings plus savings" argument, which the author presents, is an involved economic fallacy—a fallacy which becomes apparent when the same reasoning (used in the article in the case of shipping) is applied to the merchandise import and export balances. Thus, one can "prove" that the same trade is worth many billions to us and simultaneously to other nations, merely by reversing the monopoly assumption—in one case treating it so that we export without importing, and in the other, import without exporting—and by "computing" what we or they "earned or saved" in such cases.

Table A—National Income and Income from Shipping in Principal Countries, 1937

Denmark .....crown....	4,400	111	2.5

*Calculated at one-third of gross shipping receipts.

In addition, the statistics given in support of the allegedly typical earnings of Norwegian shipping in our trade are not typical, since they are based on the year 1940—a year in which rates were abnormal due to the war. In fact, the data given for these earnings actually are more than twice the level which normally had prevailed in previous years. Statistics to prove this point are easily obtainable and have been in Washington for years.

Furthermore, the statistics, which purport to show that Norway, Netherlands and Greece in pre-war years were dependent on dollars earned in our shipping trades, for half the sum needed to buy our goods, are misleading. The figures are of foreign rather than of American origin; and apparently list imports C. I. F., and exports F. O. B., instead of on a uniform basis. The result erroneously magnifies the surplus of imports from the United States.

Finally, the figures used ignore a true surplus of exports from Netherlands' colonies to the United States, which offsets the mother country's real import surplus. This is done simply by omitting all mention of these colonies in the tables and by failing to include their trade figures in the "Netherlands" heading. If correction is made for this, for the trade valuation error, and for certain minor corrections for goods in transit, etc., the supposed heavy unbalance against these countries in their trade with us is shown not to exist.

NATIONAL SHIPPING POLICY

Congress has enacted a national shipping policy which is often forgotten in discussion of details. It is clear and unmistakable. It is stated as follows:

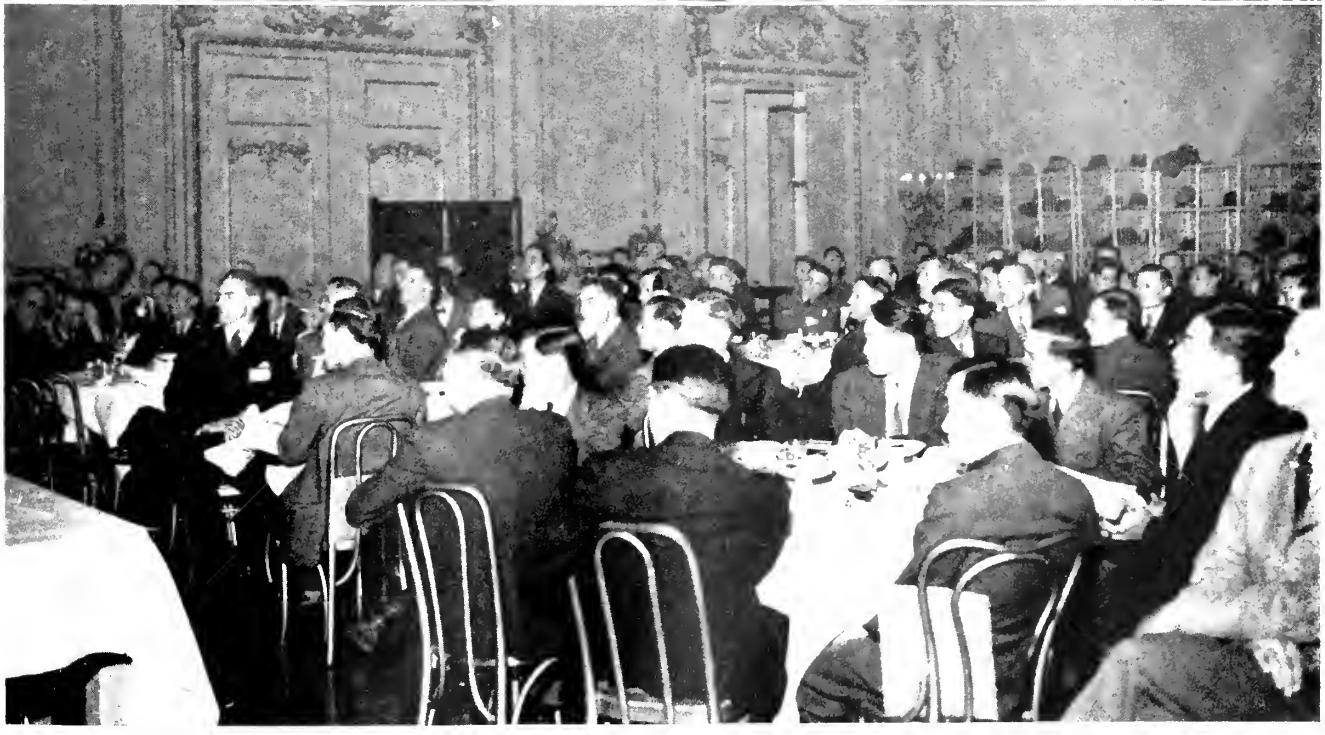
Merchant Marine Act, 1936

Title 1 — Declaration of Policy

Section 101. It is necessary for the national defense and development of its foreign and domestic commerce that the United States shall have a merchant marine (a) sufficient to carry its domestic water-borne commerce and a substantial portion of the water-borne export and import foreign commerce of the United States and to provide shipping service on all routes essential for maintaining the flow of such domestic and foreign water-borne commerce at all times, (b) capable of serving as a naval and military auxiliary in time of war or national emergency, (c) owned and operated under the United States flag by citizens of the United States insofar as may be practicable, and (d) composed of the best-equipped, safest and most suitable types of vessels, constructed in the United States and manned with a trained and efficient citizen personnel. It is hereby declared to be the policy of the United States to foster the development and encourage the maintenance of such a merchant marine."

Technicians Depart for China

At a luncheon meeting of the San Francisco Foreign Trade Association were assembled 62 Chinese technicians, who have been, along with some 900 others, completing their technical training in industrial establishments throughout the United States. Left, at the head table, is Alvin E. Eichholz, manager of the Foreign Trade Department, San Francisco Chamber of Commerce. Third from left, and presiding, is Fred Galbreath, manager, Marine Office of America, and first vice president of the association. Far right, Lyford M. Morris, president Junior Foreign Trade Association. Lower picture: General view of members and guests.



Silk is Back

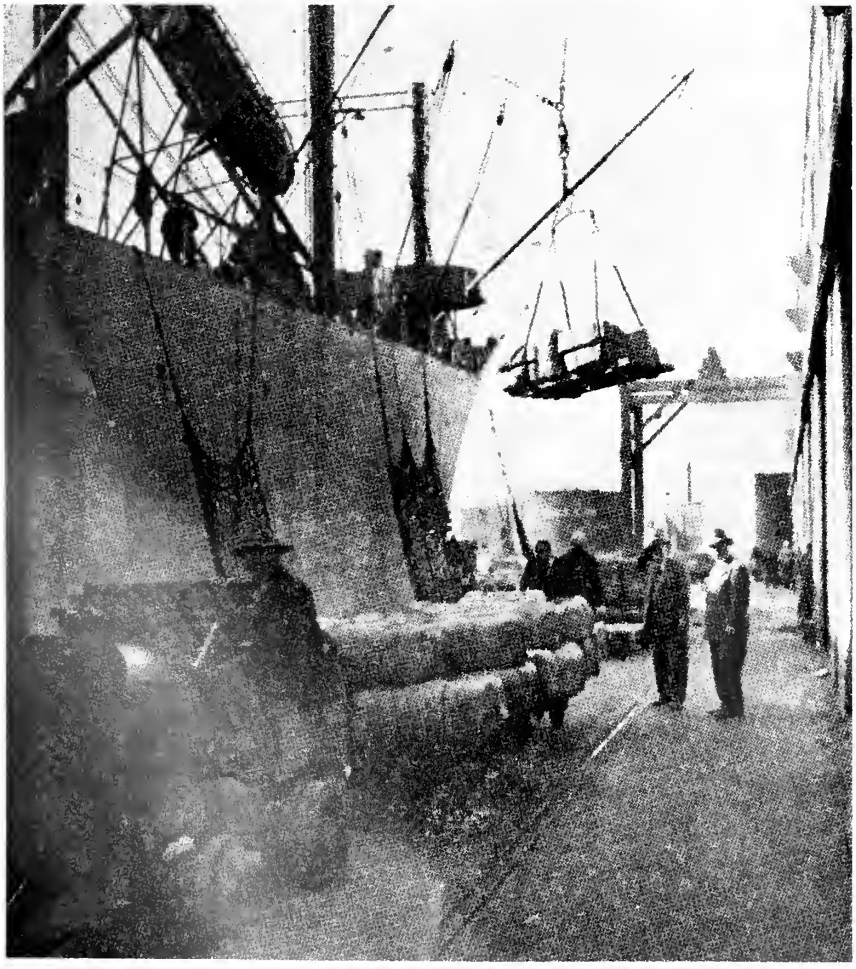
First Postwar Imports of China Goods

The first substantial commercial shipments of Chinese merchandise since the war have arrived in San Francisco on the S. S. "President Grant" of the American President Lines. Included in the cargo were 500 bales of long-awaited raw silk from China, shipped to this country from Shanghai by the Central Trust of China under the auspices of the University Trading Corporation in New York City, the Chinese government purchasing and sales agency here. Additional silk shipments are expected within the near future as sizable amounts are reported in Shanghai awaiting shipment.

Also on the "President Grant" were 575 drums of China wood oil consigned by the China Vegetable Oil Corporation to the Pacific Vegetable Oil Corporation of San Francisco. This company expects to receive shortly from Shanghai and Hongkong additional quanties of wood oil; also aniseed oil. Other commodities arriving on the steamer included 250 cases of bristles consigned to the Bank of China, cotton goods, silk piece goods, furs and skins, linen goods, porcelain ware, straw braid, feathers, curios, hemp hats, and miscellaneous Chinese merchandise.

This shipment marks an important step in the resumption of normal trade between China and the United States. As facilities in China are restored to normal operation, it is expected that the flow of Chinese exports to this country will increase steadily.

First raw silk to arrive from the Orient since before Pearl Harbor being unloaded from the S. S. President Grant at San Francisco January 6.



Large Imports from China Predicted

A substantial volume of exports from China to the United States during the next few years is indicated by estimates of the volume of Chinese commodities available for shipment abroad received by the China-America Council of Commerce and Industry from official Chinese sources. These figures, the first official estimates of post-war Chinese exports to be received in this country, show that after a transition period to allow for revival of production and transportation in the formerly occupied areas, China will be able to ship considerably larger quantities of her basic export commodities than before the outbreak of the Sino-Japanese war in 1937.

In the three years before the Sino-Japanese war, exports from China proper (not including Manchuria and Formosa) averaged $222,000,000. Judging by the latest estimates, it should be possible to exceed that total within a few years. In the first year after resumption of regular trade, however, shipments are expected to be considerably below the pre-war figure for most items. Among the major Chinese export commodities for which considerably increased shipments are predicted in the post-war years as compared with the pre-war period, 1935-1937, are tung oil, bristles, raw silk, wool, tea, egg products, tin and antimony. Large shipments are predicted also of other well-known Chinese staples, such as sausage casings, hides and skins, oil seeds, beans, feathers, medical substances, and tungsten ore. Certain manufactured products, which found

a large market abroad before the war, are also expected to figure prominently in the post-war export list. This applies particularly to such items as handkerchiefs, linens, embroideries, laces and hairnets.

A favorable market is predicted for wood oil, shipments of which from China proper averaged $21,000,000 a year in the pre-war period. The same is true of furs and skins, of which China exported more than $9,000,000 a year, and of wool, of which she shipped almost $6,000,000 annually. Before the war China exported raw silk to the value of over $12,000,000 annually. Despite the decreased consumption, due to competition from rayon and nylon, it is believed that this figure can be considerably exceeded because of weakened Japanese competition. Similarly, hog bristles, of which China formerly shipped around $7,000,000 a year, are expected to find a brisk demand notwithstanding the recent development of the synthetic variety.

Vegetable seeds and oils, including sesame seeds, tea oil, perilla oil, peanut oil and cotton seed oil, are expected to enjoy substantial sales in the U. S. and other countries. In the 1935-37 period, U. S. imports from China of these items exceeded $6,000,000 a year. During those years China shipped to this country each year handkerchiefs, embroideries, laces and trimmings and hairnets to the value of about $6,000,000, and American importers are again actively in the market for these materials. Exports of egg products from China before the war averaged $13,000,000 a year and they are again expected to have a large sale abroad. Certain minerals and ores, of which China is the major producer, particularly tin, antimony and tungsten ore, will again be available. The U. S. alone formerly took from China more than $5,000,000 a year of these three items.

Exports from Manchuria and Formosa

In addition to China proper, Manchuria and Formosa, now under Chinese control, will provide a large volume of goods for export. In the three years prior to the "Mukden incident" Manchuria alone exported an annual average of $150,000,000 of its products to other nations and to China proper, most important of which were soya beans, bean oil and cakes, coal, millet and corn, and iron and steel. In the years before the Japanese occupation, Manchuria enjoyed a substantial excess of exports over imports and helped to balance the total trade of China. Under Japanese domination exports continued at a high level, but Japan took an increasing proportion of the total, amounting to 55 per cent in 1939. About 15 per cent was exported to China proper.

Although exports from Manchuria will probably decline in the first post-war years, due to decreased production, increased domestic consumption and reduced shipments to Japan, they will still be substantial. In the past years only an insignificant proportion of Manchurian exports went to this country. It is expected, however, that in the future such products as raw silk, and hides, skins and furs will be shipped to the United States in increased quantities.

In 1936-1937, Formosa's exports, mainly agricultural products, were valued at an annual average of $115,000,000. The bulk of these shipments went to Japan in exchange for manufactured goods. Formosa's exports in post-war years will continue to be large but for some time much of her sugar, rice, forest products, tea and alcohol, which constitute the bulk of her exports, will be required for shipment to the mainland of China. Nevertheless it is predicted that exports of tea will be expanded and that the United States will buy more than in pre-war years.

In the 1935-1937 period the United States took a little over a quarter of China's exports. Chinese authorities believe that in the post-war period a much larger proportion of their exports will go to this country. To help pay for the vastly increased purchases planned in the United States for the Chinese industrialization program, China will make special efforts to develop the export of those items which are in good demand in this country.

It is expected that the Chinese export trade will be handled mainly by private interests. Chinese authorities state, however, that the commodity testing bureaus set up by the government for the purpose of improving the quality of the principal export items will be continued in operation after the war. These bureaus are expected to be of great value in helping Chinese exporters meet the requirements of foreign markets.

A. Viola Smith

Representative in China

In preparation for the opening up of active trade relations with China, Miss A. Viola Smith, who for the past two years has been the China-America Council's Washington representative, sailed on February 23 from Seattle for Shanghai, where she will be the China representative of the Council. Miss Smith, former Trade Commissioner and Consul in Shanghai, spent more than twenty years in China as an official of the U. S. Commerce and State Departments.

Miss Smith was the first woman to be appointed into the Foreign Trade Service of the United States. As Registrar of the China Trade Act, the Federal incorporation law designed especially to facilitate American business with China, she was in close touch with the problems confronting American concerns in the China trade. She has traveled extensively all over China — covering 100,000 miles by automobile alone — and is well known in governmental and business circles in every part of that country.

Westinghouse Plans Expanded Export Trade From West Coast

R. H. MacGillivray

To further plans for expanding export trade to Australia, the Orient and Western South America, Chas. A. Dostal, Vice President in charge of the Pacific Coast District for the Westinghouse Electric Corporation, announces the appointment of R. H. MacGillivray as regional supervisor of the Pacific Coast area for the Westinghouse Electric International Company, headquarters in San Francisco.

As representative of the International Company (foreign distributors for the parent Westinghouse Electric Corporation), Mr. MacGillivray will cooperate with Pacific Coast exporters and importers in the promotion of foreign business. He will be responsible for increasing export trade volume for Westinghouse by assisting in the detailed handling of all equipment to be negotiated, sold or installed in the Pacific basin.

In making the announcement, Mr. Dostal said the appointment represents a "first step" in the International Company's program to expand interests in the growing volume of export trade centered in the West Coast area.

West Coast Key to Pacific Trade

Mr. MacGillivray pointed out that "the West Coast represents the key to unlimited opportunities in domestic and foreign trade because of its rapid and continued manufacturing expansion and its natural position as a gateway for the flow of American goods now in such heavy demand by those lands in the Pacific area and the Orient.

"These factors have made Westinghouse confident that, with war restrictions gradually ending, much of its export business will originate on this Coast," he said. "It is our desire to cooperate in every way with local export representatives in making Westinghouse products available in the vast Pacific territory which the West Coast services."

Prior to assuming the newly-created post, Mr. MacGillivray was regional export supervisor in Washington, D. C., where during the war years he helped meet the electrical requirements of the Allied Nations by making Westinghouse equipment available to foreign government missions in cooperation with United States government agencies.

A veteran of the Westinghouse organization, he joined the company in 1922 as an industrial sales engineer. Since then he has filled various positions including merchandise manager of the Northern New York area, headquarters syndicate representative, and other important posts.

A native of New York, Mr. MacGillivray was educated in schools there and prior to now has centered his activities on the Atlantic Seaboard. He is an active member of the American Institute of Electrical Engineers.

WORLD TRADE ASSISTANT APPOINTED

Appointment of Karl F. Koenig as assistant manager of the World Trade Department of the San Francisco Chamber of Commerce is announced by Louis B. Lundborg, general manager of the Chamber.

Koenig is a native San Franciscan and University of California graduate of the College of Commerce, majoring in foreign trade. He has traveled extensively in Europe and has a knowledge of German, Spanish and French.

From 1930 until his entry into the armed services in 1942, he served in the International Banking Department of the Bank of America. For five years he acted as the bank's assistant foreign exchange trader, later transferring to the Letter of Credit Department, where he handled Acceptance financing of imports and exports and other financial responsibilities.

After 3 years' service in the Army as an administrative officer assigned to the Air Corps, Koenig returned to inactive duty early in 1944. He joined the U. S. Treasury Department Procurement Division, in the Office of Surplus Property, at that time known as the Federal Property Utilization Branch. Here he served as assistant to the Division Chief, until his appointment as Chief of the General Accounts Section of the Finance Division.

Karl F. Koenig

L. A. Chamber Expands Foreign Trade Department

With the development of foreign markets for Los Angeles county's products as its major objective for 1946, the Los Angeles Chamber of Commerce through General Manager Harold W. Wright, has announced a series of expansions in the organization's World Trade Department.

Stanley T. Olafson, now manager of the department with which he has been associated for the past eighteen years, succeeded the late Clarence H. Matson. With the help of an enlarged staff he plans to accelerate the trade development program. Mr. Olafson will establish all policies of the organization upon the advice of the World Trade committee and direct the activities of the entire staff. He also will be in charge of the Chamber's policies in harbor affairs.

John A. Sowers, former manager of the Domestic and Foreign Trade department of the Oakland Chamber of Commerce will assist him. Mr. Sowers was born in Ohio, and educated at Annapolis, George Washington and Georgetown Universities, and the University of California. His broad experience includes the teaching of social science, export management, advertising and merchandising and foreign trade. He has traveled extensively in the Pacific littoral. Mr. Sowers personally will direct the Orient division of the department.

Robert V. Nimmey has been added to the department to direct the British Empire division. He has traveled throughout the British Empire, represented numerous American firms, and has had considerable manufacturing experience. Born and educated in England, Mr. Nimmey is a naturalized American citizen. He has handled the export of merchandise for several American firms.

In charge of the European division of the World Trade department will be William J. Dunkerely, a former member of the staff who recently returned from the service where he was a captain in the United States Army. His past experience in the department, plus his service abroad will qualify him for his new work.

Shown left to right are: Robert Nimmey, John Sowers, Stanley Olafson, Justin Gleichauf and William Dunkerely of the recently expanded Foreign Trade Department of the Los Angeles Chamber of Commerce. Mr. Olafson is manager of the department.

The Latin American division will be under the direction of Justin Gleichauf, who joined the Chamber staff two years ago. Mr. Gleichauf has traveled extensively throughout Latin American in the interest of foreign trade. Other members of the staff are John M. Costello, former congressman from Southern California who is in charge of the Washington office of the Los Angeles Chamber; and Harry O. Johnson who maintains permanent headquarters in Mexico City.

TWA Now Compiling Foreign Trade Index

An Index of Foreign Trade Opportunities is now being compiled by the local office of Transcontinental & Western Air, Inc., through the facilities of TWA's International Division. Information in the Index will cover Europe, the Middle East and the Mediterranean Areas.

Details include products offered for export to the United States and names and addresses of firms which are interested in importing products from the United States.

Silk to San Francisco

A cargo of eleven hundred bales of Japanese raw silk reached San Francisco April 1. The precious cargo is aboard the SS Trinity Victory, which sailed from Yokohama March 19 direct for San Francisco. The vessel is operated by the President Lines as agent for the War Shipping Administration. Destined for eastern mills, the silk will soon be processed into stockings and lingerie and other scarce items of milady's wardrobe.

Freight Forwarder Legislation

Establishment of a legally authorized and Interstate Commerce Commission supervised basis of compensation for freight forwarders' use of motor trucks in their assembling and distribution services is the objective of a bill, H. R. 2764, which became law.

For nearly nine years, since the ICC in July, 1937, ruled that it had no jurisdiction over freight forwarders and that forwarder-truck joint rates were illegal, these services, held by shippers and consignees in the smaller cities to be a vital part of freight forwarder service, necessary to enable them to compete with industries in the large cities, have been in an uncertain state.

Although the Supreme Court sustained the ICC decisions, the Commission repeatedly postponed the termination date for the services, until Congress in May, 1942, passed legislation placing freight forwarders under ICC regulation.

Under the 1942 Act truckers were authorized to file assembling and distribution rates available to freight forwarders "and others" able to utilize them under like conditions in conjunction with through carload or truckload movements. Eighteen months were allowed for the establishment of such rates, during which existing joint rates might be continued.

Little progress was made in effecting the new system. Congress in emergency acts granted first another 18 months, and then an additional nine months ending last February 15. But, meanwhile, it appeared that the truckers were unwilling to file rates available to all able to utilize them as part of a through movement, and the bill just passed was drafted to authorize rates only for freight forwarders.

Under it the ICC is directed to determine and prescribe at the earliest practicable time reasonable terms and conditions governing agreements between forwarders and common carriers, pending which time the present joint rates may be continued. The agreements must be filed with the Commission and are subject to its approval.

While the new act permits separate special treatment of forwarders, it leaves untouched the provisions of the 1942 Act under which truckers are authorized to make special rates available to any shippers or groups of shippers able to utilize the truck services for assembly and distribution in connection with through consolidated movements.

Dictionary of Foreign Trade

Called a "dictionary" a new book by Frank Henius and published by Prentice-Hall, Inc., might well be called an encyclopedia. It contains 745 pages of vital information for the foreign trader and for every one concerned with shipping.

The book is intended to bring together in one volume a definition of foreign trade terms, usages, practices and procedures. Every effort has been made to supply complete and specific information in every case, even to the point of listing and explaining the many abbreviations used in international trade. The author has drawn on 40 years of experience—as a foreign trader and counselor, and in order to give as much aid as possible to those who may be just entering the field of foreign trade, and to peoples of foreign countries who desire to understand the trade terms and practices which they encounter in dealing with us, there is detailed explanation of many terms that might otherwise be deemed unnecessary.

The book fills a real need and is very timely. The price is $10.00.

Want to Travel?

If you want to go abroad on a business trip, see the U. S. Commerce Department. That government agency is now allocating passenger accommodations, both plane and ship, on return trips from Europe and on travel to and from India, Africa, the Middle East, and the Far East. Priorities are not needed for space to Europe. The Department says preference is given to businessmen whose travel will be more effective in expanding exports and imports and in increasing employment in the U. S.

250,000 MILES

The Essex, first of her class of aircraft carriers to be commissioned, established a remarkable distance record. She covered a quarter of a million miles of ocean, averaging 240 miles a day for every day since commissioning, including the very few days in port, until the war's end. This is more mileage than would normally be expected in the entire lifetime of a capital fighting ship. To the immense satisfaction of the Navy and of the Westinghouse men who designed and built her propulsion machinery, the turbines and gears required only routine maintenance.

Diesel Workboats for Overseas Service

Socony-Vacuum Builds Fleet of Diesel-Powered Vessels, and Dump Barges, for South American and Netherlands Indies Operations

By T. Orchard Lisle

While the operation of ocean-going tankers is generally recognized as an oil company's normal business function, it is not so widely realized that a host of smaller craft of numerous types form part of oil industry fleets at home and abroad.

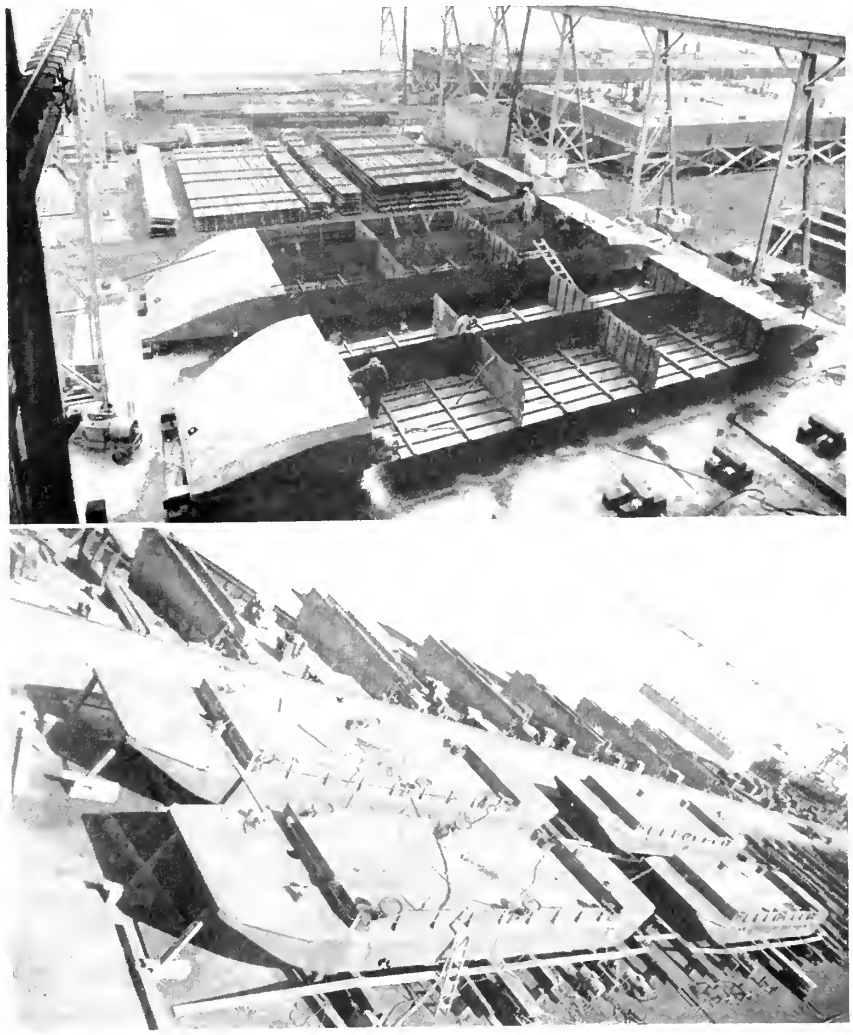
The smaller class of vessels for the petroleum industry is typified in the river tugs, house barges, oil barges and launches built last year as well as now under construction for the marine transportation department of the Socony-Vacuum Oil Company, Inc., New York, for the overseas operations of subsidiary and affiliated companies. This particular fleet consists of a total of 63 new craft.

In 1945, the company built three twin-screw and three single-screw, tunnel stern, shallow draft towboats and sixteen house barges in Eastern Venezuela for use by the Socony-Vacuum Oil Company of Venezuela, in exploration work on the Orinoco River and its tributary waters. Now under construction are 41 towboats, oil barges, staff launches, mooring launches and service launches for South America and for the Netherlands Indies. The latter order will represent a substantial investment, and consists of twelve staff launches; two service launches; four mooring launches; five towboats and eighteen barges. All but the barges are diesel powered.

The vessels built last year were fabricated in the United States by the Chicago Bridge and Iron Company, and were built on temporary ways on a beach at Guira, Eastern Venezuela, by native labor under the direction of F. X. Sullivan of the Marine Transportation Department of Socony-Vacuum. These boats provide accommodation and transportation for exploration, seismograph and drilling crews from Cuidad Bolivar as far as the foothills of the Andes about 1,000 miles up the Orinoco. The rainy season there lasts about nine months, making the work of the exploring parties arduous and unpleasant, especially as they are obliged to go up the tributary rivers and swampy areas where no white man has previously penetrated.

While the work was under way at Guira everything possible seemed to block progress. There were several earthquakes; a revolution; storms washed away the underpinning of the makeshift ways; and one ship carrying supplies to the yard suffered a collision and ran ashore, while another freighter with additional supplies caught fire at her pier in Brooklyn. Finally the boats were completed. Then they had to make a risky, rough-weather crossing over the 35 miles of Gulf of Paria and 300 miles over water separating the yard from the base at Cuidad Bolivar. Some damage was done, but all craft

Oil barges under construction at Decatur Plant of Ingalls Shipbuilding Corp.



Above and right center: Four of the 16 house barges an the erection ways at Guira, eastern Venezuela.

made the trip and no lives were lost. Each of the tugs is powered with Mack diesel engines, and has sleeping accommodation for four men, while the house barges can sleep up to 20 persons.

With further regard to the fleet now under construction, eight of the barges are for South America and these are being fabricated at the Birmingham yard of the Ingalls Shipbuilding Company and will be erected abroad. The ten barges for Sumatra, Netherlands Indies are for the Standard-Vacuum Oil Co., Inc., and are being built at Ingall's Decatur plant. They will be shipped to the Netherlands Indies complete and ready for operation. Lack of unloading facilities necessitates building the boats for Venezuela on the spot.

The barges are of 75 tons capacity, are of welded steel construction, and for the time being some will be used for carrying deck cargo, and later be converted to carrying bulk oil. Each is 69 ft. long by 10 ft. beam and 4 ft. 3 in. moulded depth, with 2 ft. 3 in. loaded draft. Each hull is divided by four watertight transverse bulkheads and one centerline bulkhead. There are slight variations in the equipment specifications, as some will be operated by the Cia. de Petrolio, some by the Socony-Vacuum of Venezuela, and others by the Colombian Petroleum Company. One safety feature is the fitting of Vac-Rel relief valves to the cargo tanks on all of the barges.

One of the steel towboats built in 1945 and now in service on the Orinoco River.

The five towboats for the 1946 program are also of steel construction, and are being built by Higgins of New Orleans. Their length is 48 ft. by 13 ft. 4 in. beam and 4 ft. 3 in. draft. Each is being powered with two Buda diesel engines of 125 hp. at 1,400 rpm., driving twin 32 in. diameter bronze propellers of Socony-Vacuum design at 715 rpm. in tunnels in the stern. Reduction gears are installed between the engines and the propeller shaft. The latter is of 2⅜-inch diameter Monel metal, and they run through Micarta-lined stern bearings.

For starting and lighting there are two sets of 200 amp. hour, 30-volt, Exide storage batteries, and these are kept charged by the 750-watt, 32-volt generators on the main engines. The exhausts are carried through Maxim silencers and spark arrestors in the stack. Fuel for the engines passes through Purolator filters. The fresh water cooling system being closed, the supply runs through coil-

welded steel pipes arranged outside the bilge plates on both sides of the hull. In addition to navigating lights, cabin light fixtures, there are two half-mile searchlights. All the towboats will be operated by native crews under the direction of a company port captain.

The staff launches, the service launches and mooring launches, all of which are diesel driven, are now being built by Higgins of New Orleans. One staff launch is for the South American Gulf Oil Co., for operation in Colombia. This com-

pany is owned jointly by Socony-Vacuum and the Texas Company. Two staff launches are for the Socony-Vacuum Oil Company of Venezuela, while nine staff launches are for Socony-Vacuum Oil Company of Colombia. Two service launches and four mooring launches will be shipped to Sumatra, where they will be operated by the Standard-Vacuum Oil Company, which is jointly owned by Socony-Vacuum and the Standard Oil Company of New Jersey.

These eighteen craft are all 30 ft. by 5 ft. 9 in. by 3 ft. 4½ in. They are to be used for the transportation of survey and seismograph parties. An interesting feature of the hull, which was designed by W. D. Fletcher, supervisor of technical section of Socony-Vacuum's marine construction and repair division, is the diagonal placing of the frames, all of which are straight and connected to a one-inch steel pipe at the chine and to a two-inch pipe at the keel, the latter being used for cooling the engine water. The cooling system is closed and uses fresh water. While the hulls are mainly welded the diagonals may be riveted to the plates.

Each boat is powered with a six-cylinder, 3⅝ in. by 5⅛ in. Buda marine diesel engine turning at 1,600 rpm. and driving through a reverse gear. The propeller is a Columbian, 16-inch diameter by 14-inch pitch, and having an 0.63 area ratio. The propeller shafts are of 1⅝ in. diameter, and run through Goodrich rubber stern frame bearings. Hulls are of the V-type with hard chine form and flat bottoms. Their speed is 16 land miles, or 14.1 knots. Maxim silencers are fitted to the engine exhausts which are carried through the side of the hull above the waterline.

The staff launches are of the open type with canopies for protection from the sun and rain. There are short decks fore and aft, and a cockpit forward, while the after cockpit is large enough to carry the seismograph instruments. In the engine room, forward, there are two six-volt, 204 ampere hour Willard storage batteries, while aft of the engine is a 58-gallon fuel tank. Engine controls and the steering wheel are at the forward end of the after cockpit, the engine being fitted with a Columbian Bronze Corp's Bowden wire control, while the engine is fitted on Micarta chocks bolted in place.

In the case of the service launches, the engine controls and steering wheel are in the forward cockpit, which has a wooden roof. In the after cockpit there are insulated compartments, the one on the port side being for ice and the one on the starboard side being for food storage. There is a cabin with a portable table, seats and two lockers, and there is a toilet under one of the seats. Under the after deck there is a 20-gallon tinned copper drinking water tank. These boats mainly differ from the staff launches in that they have a cabin, and are designed for the particular operating conditions of the Netherlands Indies, whereas the staff launches are for operating in Venezuelan and Colombian inland waters, several hundred miles north of the Equator.

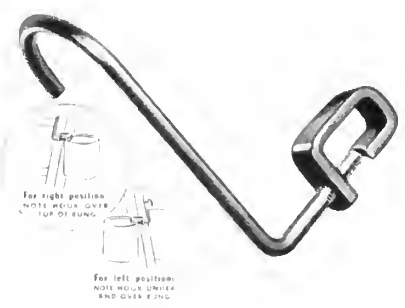
Harold F. Sheets, chairman of the board of Socony-Vacuum Oil Company, Inc., of New York, was a Pacific Coast visitor in March inspecting properties and operations of the General Petroleum Carporatian, a Sacony-Vacuum affiliate, and giving special attention to marine terminal facilities. Having lived abroad for many years in the interests of foreign marketing by his company, Mr. Sheets is regarded an expert in world trade affairs. He predicts a bright future for Pacific ports and shipping. While in Los Angeles, he was the honored guest and speaker at a luncheon meeting of prominent industrialists and civic leaders. In the photograph below he is pictured with General Petroleum officers. Left to right are C. S. Beesemeyer, Vice-President and Director of Marketing; President S. J. Dickey, Mr. Sheets, R. A. Sperry, Vice-President.

Paint Hooks That Fit Any Ladder and Any Size Can

The new Persson Paint Hook puts the paint can in its right place, provides the answer to spilled cans, wasted paint, and costly accidents. There is no bothersome can handle to interfere with the brush; the can opening is left entirely free for dipping and stirring; and the can is placed exactly where needed for ease in painting, with safe, secure positioning at all times.

A slight, simple adjustment permits the can to be hung on right or left side of ladder. For right position, the hook is slipped over the top of rung. For left position the hook goes under and over the rung. A quarter turn on the clamp places the paint can in upright position.

Two cans may be hung on opposite sides of any ladder, without interference to the painter. Persson Hooks leave both hands free for neat, rapid painting. In addition these hooks are suitable for use with most other receptacles. The location of the ladder may be changed without removing receptacle.



"Pick" Passes

Noted Accident Prevention Expert Dies Very Suddenly

Byron O. Pickard, popularly known as "Pick" and for nearly 20 years Manager of the Accident Prevention Bureau of the Waterfront Employers Association of the Pacific Coast, died very suddenly at his Berkeley, California, home on March 7th. He had worked at his office all day on March 6th but early on the morning of March 7th had a heart attack and passed away in a few minutes.

Born October 27, 1882, in Omaha, Nebraska, he came to California sometime before the age of twenty, and studied mining engineering at the University of California from 1902-1905 when he transferred to the Michigan College of Mines, taking his B. S. and E. M. degrees there in 1907.

He opened his own business in Douglas, Arizona, operating as a Mining Engineer in that state and Mexico until 1917, when he entered the U. S. Bureau of Mines as Assistant Chief Safety Engineer. At that time he was located at Pittsburgh, Pa. He was shortly transferred to Washington, D. C., where he became the Assistant Chief Mining Engineer of the Bureau. He was transferred from there to the Lake Superior district as the Mining Engineer for the Bureau, with headquarters at Houghton, Michigan.

In 1918 he became Administrative District Engineer of the Western Division, comprising the states of Oregon, California, Arizona, and Nevada, with his headquarters in Berkeley. From then until 1927, he trained rescue crews for the Bureau of Mines and directed rescue operations at the Argonaut Mine disaster in 1922.

He was a member and Past Master of Hillcrest Lodge 573, F & A. M., a member of the Theta Tau Honor Society and the Theta Chi Fraternity, a member and past president of the A.S.S.E. and past chairman of the marine section of the National Safety Council in 1938. He was active in the Propeller Club and was a past chairman of the House Committee.

During the second world war he was California State Chairman of the National Committee for Conservation of Manpower in War Industries, and taught safety engineering courses in the Bay Area under the auspices of the University of California.

He is survived by his wife, Mrs. B. O. Pickard, and two daughters, Miss Bonnie Pickard and Mrs. Ellsworth Rose, also his mother, Mrs. O. J. Pickard, and sister, Mrs. J. J. Jorgensen, both of Denver, Colorado, and another sister, Mrs. L. C. Wehlers of Omaha, Nebraska.

Byron O. Pickard

Byron Pickard was a pioneer in accident prevention work for the longshoremen. Under his patient, careful, expert guidance were brought out the first codes for safety on docks; safe practices for longshoremen on ships, safety for seamen and longshoremen incorporated in ship design, and others. Several of these codes became models for similar work on other coasts. This work begun in San Francisco soon made its importance and its economy felt in other ports and under Pickard the ports of the Pacific Coast became unified and standardized in their safety programs.

The reduction in accident frequency rates has been very impressive over the past 20 years, sufficiently so to bring substantial reductions in insurance rates. The Accident Prevention Bureau was able under Pick's leading to create great interest in safety meetings and to maintain the sympathetic interest and support of its sponsors to a degree perhaps never before attained by any American cooperative maritime effort.

As a tribute to this man who was a dear personal friend of more than one member of the Pacific Marine Review staff we quote from "The Preventer," his own brainchild, the eulogy composed by his associates.

"While we admire men for what they accomplish, we love them for what they are. As a pioneer in accident prevention, Byron O. Pickard is respected throughout the country. Of those hundreds fortunate enough to have known Pick personally, few could help but love him for his constant consideration for the feelings of others, his ever-youthful enthusiasm tempered by mature wisdom, his very human prejudices in little things and his great toleration and open-mindedness in the things that mattered in his work, his willingness to drive himself to the very limit of his endurance, and his equal ability to relax and enjoy himself with his friends.

"Pick's work could never be finished because he always had a further goal when one objective was reached. But he has left an idea and an inspiration to guide us and the memory of a warm friend to make our lives happier."

Correction of Unsatisfactory Brush Performance

The maintenance of satisfactory performance of commutating equipment necessitates watchfulness and care on the part of the operator. This is especially true at times such as these when heavy production schedules, long hours and peak loads place an added burden on all power equipment. Commutators in poor condition should be re-surfaced at the first opportunity, carefully inspected for feather-edge mica, if undercut, and kept in good condition by daily application of a canvas wiper as described heretofore. At the first indication of unsatisfactory performance the cause should be sought and the faulty condition corrected before serious damage is done.

Some potential sources of operating difficulties can be detected before trouble occurs. Others are less evident and the first indication of their presence appears in some such form as imperfections of the commutator surface, visible sparking, excessive heating or brush noise. The same fault may give more than one indication of its presence, or the first indication to appear may itself cause others to follow. For example, sparking may be the immediate cause of poor commutator surface and that, in turn, lead to noisy operation which can be permanently relieved only when the primary cause of sparking has been determined and eliminated. There is of necessity, therefore, considerable overlapping in the discussion of these readily detected indications of less obvious faults.

Sources Of Poor Commutator Surface

Defects in commutator surface arise from many causes and likewise occur in many varied forms. Mechanial faults, such as rough edges on bars, uneven surface, eccentricity and high or low bars, call for resurfacing, for which approved methods have been discussed. If high or low bars are observed the tightness of the commutator should be checked and "V" ring or clamping bolts tightened when looseness is evident. After undercutting, the commutator should be carefully inspected for feather-edge mica, or mica fins, since this is an all too common source of poor commutator surface and sparking.

Streaking and Threading

Circumferential streaks in the commutator surface may result from mica flakes, copper or other foreign material embedded in the brush faces. If mica or copper is noted, inspect the commutator for mica fins. In case of copper in the brush faces look also for a source of abrasion or evidence of poor commutation, especially evidence of high current density in restricted portions of the brush face. The latter condition is frequently indicated by a dull or etched band, parallel to brush width, at that portion of the brush face where the high current density occurs. In extreme cases this condition may lead to "pitting" of the brush faces to appreciable depth. Localized bands of high current density result from a faulty commutation cycle, usually too rapid reversal of current or over- or under-commutation. Such a condition can often be corrected by shifting the brush position or by changing the interpole field strength. It is not advisable, on interpole machines, to shift the brushes far from the neutral point. Should a moderate shifting of the brushes not improve performance sufficiently, further improvement should be obtained by adjusting the interpole field strength.

If an abrasive brush grade is used, and streaking or copper deposit is noted, a less abrasive grade should relieve the trouble. The presence of oil on the commutator surface increases the tendency of copper to accumulate on the faces of the brushes and cause streaking. Low average current density in the brush faces is another condition which sometimes results in streaking of the commutator surface. This effect, which occurs most frequently with lampblack base, electro-graphitic brushes, can usually be corrected by removing some of the brushes of each polarity, thus raising the current density, or by using a brush grade having better film forming properties.

Threading, i. e., fine, threadlike grooves in the commutator surface, usually represents an advanced stage of streaking and results from similar causes.

Bar Etching and Burning

Bar etching or incipient burning of commutator bars usually results from visible sparking or a band of very high current density in the brush face producing interface sparking not noticeable at the edges of the brush. Adjustment of the brush position or interpole field strength should correct this condition if the source lies in imperfect compensation during the commutation period. There are, however, various other causes of sparking which will be summarized later. Feather-edge mica is such a frequent source of bar etching and burning that it should be one of first causes sought when this trouble develops, especially if it appears at isolated sections along the edge of the bar.

Burned bars, unless the result of

some transient fault such as a flashover or an external short circuit, represent merely an advanced stage of bar etching and their prevention is accomplished in like manner. If the burning is severe the commutator should be resurfaced after the primary source of the burning has been corrected.

Pole Pitch Marking

One cause of etched and burned bars is a loose or high resistance connection between the end of an armature coil and the commutator riser. These poor connections, which may have considerable resistance when the armature is revolving, may make firm contact when the armature is at rest and, for this reason, are too often hard to detect by measurement of the connection resistance with the machine at standstill. However, they can be located by the resulting bar marking which appears on the bar immediately ahead of the one with the poor connection. In Figure 1, a high resistance connection to commutator segment No. 2 is indicated by the dotted line connecting it to the armature winding. Coil A is carrying the full load current of one armature path which, in the relation of commutator to brush shown in the upper drawing, should normally divide between segments 1 and 2. However, due to the high resistance connection of coil B to segment No. 2, most of the current in coil A is forced to flow through the rapidly narrowing contact between segment No. 1 and the brush, creating an extremely high current density which may, of itself, cause sparking and bar marking. When segment No. 1 moves from under the brush, the current concentrated at the trailing edge has to pass through coils B and C to reach a low resistance connection to the commutator. Shift of the current from segment No. 1 to segment No. 3 is retarded by the inductance in these coils and some of the current jumps from the trailing edge of segment No. 1 to the brush, producing a spark. If this condition is not soon recognized and corrected the resulting burning at the bar edge destroys contact with the brush and the point of last contact is at the edge of this burned area. Obviously such a condition is progressive in its action and, if not corrected, will produce a bad flat spot in the commutator.

Bar marking, usually of less severity, can generally be observed at the other end of the armature path affected, one pole pitch on the commutator from the point at which the fault exists. It is also not uncommon to find traces of marking at pole pitch intervals around the entire commutator. This results from the unbalancing of the armature circuits produced by the faulty connection. Cross connections in the armature winding tend to minimize, or entirely eliminate, this secondary marking.

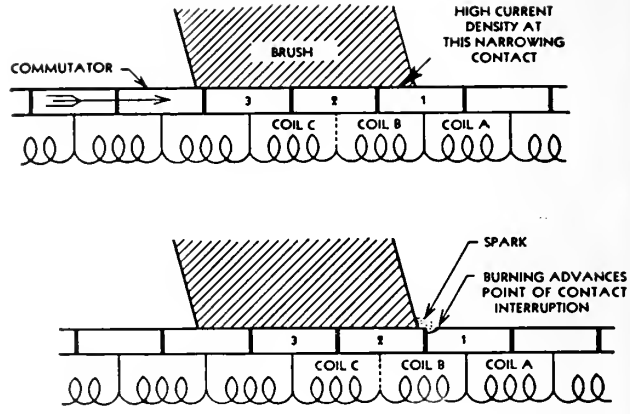

Fig. 1: A loose or high resistance connection between armature coil and commutator causes burning of the next bar ahead.

Slot Pitch Marking

Marking of every second, third of fourth bar is usually associated with the number of coils per slot. Figure 2 represents diagrammatically a machine with three coils per armature slot, only one group of three coils being shown. As drawn, commutator segment No. 2 is about to make contact with the brush, starting the commutation cycle of the leading coil in the slot. Commutation of this coil is completed when segment No. 1 leaves the brush during which time the slots carrying this group of coils will have moved to position A. Commutation of the second coil does not begin until segment No. 3 reaches the brush and the slots are in position B. The commutation cycle ends with the slots in position C. Commutation of the trailing coil in the slot occurs while the slots are moving from position D to position E. It is quite apparent that field conditions during the commutation cycle are different for each of these coils and, although the difference is exaggerated in the drawing, conditions encountered in practice may result in decided difference in commutating field encountered by two or more coils in the same slot. When this occurs there is a tendency for marking to appear on the commutator at slot pitch intervals.

If the commutating zone of the magnetic field is wide enough it may be possible to set the brushes in a position giving acceptable commutation for all coils in the slot, thus preventing recurrence of the bar marking. Should marking continue after the best brush position is found the influence of the interpole field

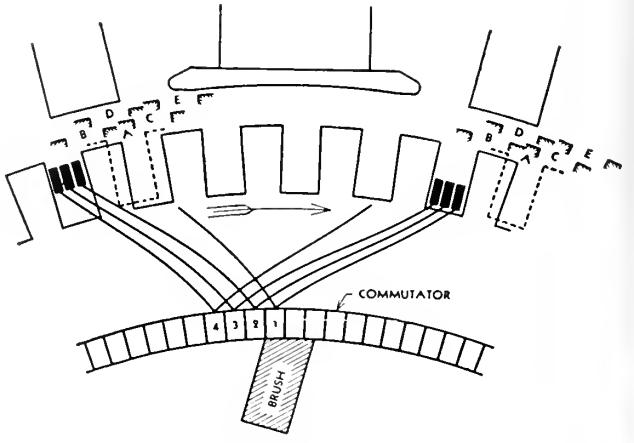

Fig. 2: With more than one coil per slot, commutation of each coil occurs at o different position in the field.

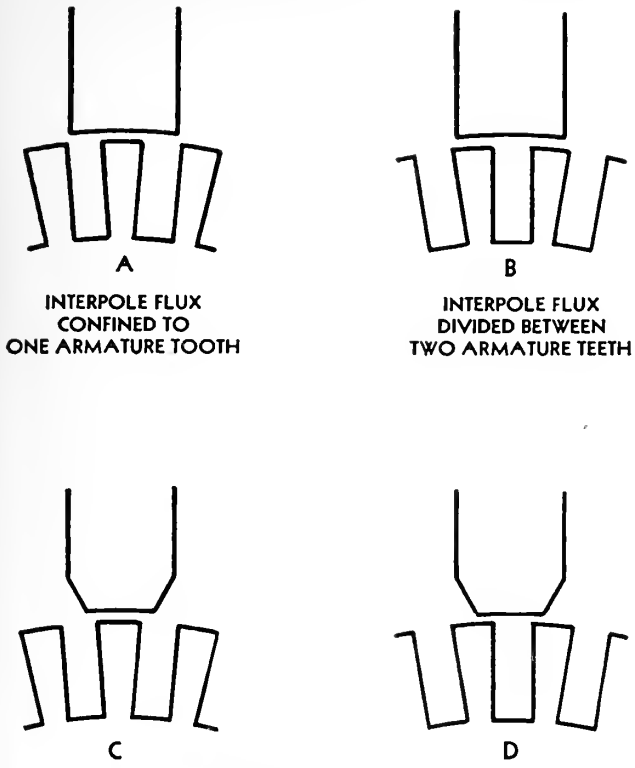

Fig. 3: Ratio of interpole flux span on armature to tooth pitch should be an integral value.

should be widened by attaching pole face shoes or increasing the interpole air gap. The interpole is often backed up by non-magnetic shims between the pole piece and the field frame. Removal of non-magnetic shims to obtain the required spread of interpole flux does not decrease the interpole strength. However, if magnetic shims are removed or the pole piece machined off, the interpole flux is reduced and should be restored to its original value. When the interpole winding is shunted this can be done by removing or increasing the resistance of the shunt; otherwise, it may be necessary to increase the number of turns on the interpole. The use of brushes with higher contact drop or with slight polishing action are other methods of reducing the tendency for commutator marking to develop on machines with more than one coil per slot.

Flat Spots

Flat spots sometimes result from merchanical causes, such as the pound from a loose bearing or unequal angular velocity on a generator driven by a reciprocating engine. As a rule, however, they result from failure to correct some faulty condition which is first indicated by burned bars and their recurrence is prevented by the correction of this condition. After the cause has been removed the commutator should be turned or ground. Sandpapering will clean off the burned surface at a flat spot but will not restore a true cylindrical contour to the commutator and the spot is liable to develop again even though the original cause has been removed.

Discoloration

Discoloration of the commutator surface may indicate excessive temperature, contaminated atmosphere or the presence of oil on the commutator. Discoloration from heat is usually recognizable as such. Sources of excessive heating and their correction will be discussed in a later portion of this article. Elimination of atmospheric contamination is often a difficult task. In many industries contamination of the atmosphere by certain chemicals cannot be entirely avoided. Many of these materials, of which chlorine, sulphur and acid fumes are examples, cause discoloration of the commutator surface and interfere with satisfactory performance. The use of brushes with mild polishing action will sometimes prevent the development of operating difficulties but, in extreme cases, air conditioning has proved to be the only means of obtaining satisfactory operation. Oil on the commutator surface tends to develop a dark, high resistance glaze which may lead to burning of the surface. It also increases the tendency for the brush faces to pick up copper. Oil sometimes creeps from the bearings to the commutator surface and is sometimes deposited from oil mist in the air. If the source cannot be removed, or the oil mist removed from the air by filtration, the use of brushes with some polishing action will usually aid in maintaining satisfactory contact with the commutator and good machine performance. Frequent use of a canvas wiper is also recommended under such conditions.

Raw Surface

A raw or bright metallic copper surface on the commutator is not desirable since a film of surface oxidation is advantageous from the standpoint of both commutation and friction. Among the more common causes of raw commutator surface are the use of abrasive brushes, serious accumulation of copper in brush faces, atmospheric contamination and operation at too low average current density. Some forms of atmospheric contamination impede or entirely prevent the development of a good surface film on the commutator or, when they occur, may destroy a surface film already established. The discussion of "contact poisons" in Modern Pyramids No. 2 cites specific examples of this effect. The use of brushes capable of developing an electro-graphitic film on the commutator surface will often improve operation under these conditions. The electro-graphitic film appears to protect the commutator surface from the contaminated air sufficiently for the desired oxide film to be formed. Raw commutator surface resulting from low average current density can usually be corrected by removing enough of the brushes to bring the current density up to an

THE SEXTANT

CHAPTER III

Errors and Adjustments of the Sextant

Just as a watch or any other fine instrument must be adjusted at regular intervals, so must a sextant be adjusted if the owner or user expects to get satisfaction from it in determining his position on the surface of the earth. However there is this difference between the adjustments of a watch and a sextant, and that is that most of the adjustments of a sextant must be made by the owner, usually out at sea far from any sextant manufacturer or any instrument concern which might make the adjustments for him. Although the average navigator takes good care of his sextant, it is not always realized that the construction of the sextant makes it an instrument which may develop errors unless it is constantly checked and adjusted.

The errors of a sextant—not including the human error in its use—are all concerned with the optical parts of the sextant, a fact which should be appreciated after having read chapter II of this series on the "Principles of the Sextant".

There are three classes of errors which either creep into a sextant while it is being used or carried around, or which are the result of imperfect manufacture. Of the latter—those errors caused by imperfect manufacture.—we can be thankful that they are few and far between. As a matter of fact no reputable manufacturer would permit an imperfect sextant to leave his factory. The reader must be aware that a great many "bootleg" sextants have appeared on the market during the past few years—sextants that bear the name of reputable manufacturers, but which were made by unskilled workmen who have traded on the names of well-known sextant makers.

But, to get back to the errors in a sextant.

I always like to classify these errors into three groups—

First, the error built into the sextant itself during its manufacture—the error which cannot be compensated for and which cannot be remedied.

Second, the error built into the sextant itself during its manufacture—the error which can be compensated for. The extent and amount of this error can be determined in a way which will be explained later.

Third, the errors which creep into a sextant caused by its being handled every day by its owner or user. This type of errors can be corrected by the owner or user, and no man should ever go to sea expecting to use a sextant unless and until he is fully familiar with the method of determining, and correcting, this latter class of errors.

These errors will be more readily understandable if they are further divided into two classes which may be termed NON-ADJUSTABLE ERRORS (or those which the user is unable to correct for himself, or which cannot under any circumstances be corrected) and ADJUSTABLE ERRORS (which the user should always be able to correct).

NON-ADUSTABLE ERRORS

These errors, which are really all errors of construction, may be further divided into three classes—

1. Graduation error.
2. Centering (or eccentricity) error.
3. Prismatic error.

1. **Graduation Error.** An error due to the fact that the divisions (degrees) on the arc are not equally spaced. This is an error due to faulty manufacture. Neither the user nor an experienced adjuster can remedy this. Any sextant which has a **graduation error** is useless.

2. **Centering (or Eccentricity Error).** This is an error of manufacture, and the user or owner has no means of determining the amount of this error, or of doing anything about it if he could determine the amount of error. It is caused by the fact that the pivot about which the index arm rotates was not placed in the exact center of the circle of which the arc is a part. Such an error varies at different positions of the index arm, generally increasing with the angle measured. The Naval Observatory at Washington is equipped to determine the amount of this error for each 10° or 15° angle. The amount of this error is noted on the CERTIFICATE OF INSPECTION issued by the Naval Observatory upon their examining and checking a sextant.

3. **Prismatic Error.** This error is sometimes called a "shade error" which is caused if the two faces of the shade glass are not ground exactly parallel. It cannot be adjusted but if suspected it may be ascertained by taking an observation with the particular shade and noting the reading, and then taking an observation without the shade, and comparing the reading. Any error found should be carefully recorded. If a combina-

tion of shades is habitually used, observations should be taken with these in a similar way.

Both the index shades and the horizon shades may be examined in this way by making contact with the direct and reflected images of the Sun, using the inverting telescope and the darker eye-piece (not forgetting to adjust the rising piece to make the two images equally bright). If, on removing the dark eye-piece and turning in the shade to be tested, the sun's images remain in contact, the shade is accurate. If, however, the images of the sun do not remain in contact then the difference in the sextant readings of their being in contact with and without the shade is the shade error for that particular shade or combination of shades.

The question of whether the error in each case is positive or negative must be carefully considered. If the index arm has to be moved higher on the arc proper to obtain contact with the faulty shade, then this error, being, so to speak, "more", is to be subtracted and is a minus (-) error. If, however, the angle to obtain contact with the faulty shade is lower (i. e., towards zero), then this error is, so to speak, "less", so is to be added and is a plus (+) error.

It should be pointed out that in modern sextants, shade error is rare and can certainly be ignored in any sextant with a CERTIFICATE OF INSPECTION. Modern manufacturing methods have eliminated this error.

Shade error can, of course, be caused by the shades becoming loose or damaged by twisting, but such a condition should be apparent at once to the careful observer. In this case the use of the shades should be discontinued until they may be properly tested and repaired and one or other of the dark eye-pieces fitted to the telescope and used. It is important to do this, as by using the telescope eye-piece any shade error is eliminated.

THE CERTIFICATE OF INSPECTION. The Naval Observatory at Washington is equipped to examine and check sextants and upon examination will issue a CERTIFICATE OF INSPECTION which includes —

1. The date sextant examined.
2. Name of sextant.
3. Serial number of sextant.
4. A tabulation showing the corrections be applied to readings of the sextant in **addition to the index** error.

From this it may seem that the residue of all these NON-ADJUSTABLE ERRORS, if any, is tabulated on this CERTIFICATE OF INSPECTION, which is pasted inside the sextant case lid.

Before you purchase a sextant, except from a reputable instrument manufacturer or dealer, make sure that—

1. A CERTIFICATE OF INSPECTION is pasted on the inside of the lid of the sextant case.
2. That this CERTIFICATE OF INSPECTION applies to that particular sextant.
3. That the CERTIFICATE OF INSPECTION bears a recent date.

ADUSTABLE ERRORS

The errors of the sextant which the user can control and correct himself are four in number. These are familiar to seamen of all the ages and are known as the FOUR ADJUSTMENTS OF THE SEXTANT. A sextant is, thusly, considered to be "in adjustment", or "out of adjustment".

THE FIRST THREE OF THESE ADJUSTMENTS MUST BE MADE IN THE ORDER NAMED: First Adjustment; Second Adjustment; Third Adjustment. The Fourth Adjustment can be made without reference to the other three.

1. **First Adjustment.** The index mirror must be perpendicular to the plane of the instrument.

2. **Second Adjustment.** The horizon glass must be perpendicular to the plane of the instrument.

3. **Third Adjustment.** The horizon glass must be parallel to the index mirrors when the index arm is set at zero (0°) on the arc.

4. **Fourth Adjustment.** The axis of the telescope when shipped (i. e., in place in the instrument) must be parallel to the plane of the instrument.

In my next article in this series I will take up these adjustments one by one and show how to determine whether or not the sextant is "in adjustment", and if not, how to adjust.

(To be continued)

Your Problems Answered

(Continued from page 359)

average of 40 amperes per square inch. Should the full complement of brushes be required to carry peak loads it is advisable to change to a grade of brush with better film forming characteristics.

Seek the Source

The importance of maintaining a good commutator surface is widely recognized but frequent reconditioning of the surface should not be necessary to attain this end. It is much better to seek the source of any faults which may appear and correct the primary defect. In this manner interruptions of service for commutator maintainence can be largely eliminated and the cost of maintenance correspondingly reduced.

Volz Flat Surface Safety Lifting Clamp

Lifting of light or heavy plates, barrels or other containers, stampings or welded assemblies, or any metal with sufficient flat surface to enable the jaws of the clamp to engage it, is facilitated through the use of the Volz flat surface lifting clamp, manufactured by Merrill Brothers, Maspeth, N. Y.

It picks up and securely holds, irrespective of position of the clamp when attached and lifted.

It releases instantly and automatically when the load or weight is relieved from the grip of the jaws.

It is claimed that this clamp has two definite clamping principles — one a pressure grip, the other a wedge grip—making it what is claimed an impossibility for the load or the article being held to slip, even though it contains a coating of grease or oil.

All working parts are used in a strong drop forging casing, eliminating thereby all danger of bent parts by exposure.

The cantilever basic principle actuates the one jaw, the stationary jaw being of special construction, which allows the tremendous wedge power and grip.

The entire device, from the shackle to the gripping jaws, is drop forged; made in four sizes, ½, 1, 3 and 6 ton capacities; and will take metal from 0" to 2" in thickness.

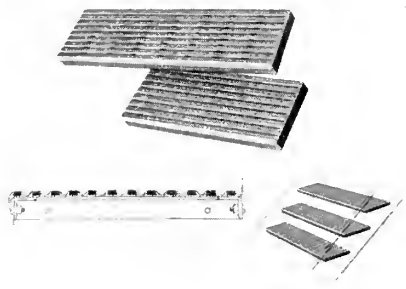
NEW EQUIPMENT AND MACHINERY FOR YARD, SHIP AND DOCK

Anti-Slip Ladder Treads

Ladder treads that combine the safety and non-slip qualities of a safe-groove type tread with structural sections to form a substantial ladder tread are now manufactured by Wooster Products, Inc., Wooster, Ohio. The anti-slip protection is afforded by the abrasive grit filler in the safe-groove tread.

These ladder treads require little maintenance. The corrugated surface of the tread section is self-draining and the abrasive surfaces are not usually affected by oil or grease or icing in cold weather. The grooves in the tread section provide drainage and are also a depository for loose dirt and debris so that the walkway surfaces are kept clean; 1/8" by 3/4" drainage slots in grooves of the tread section can be punched in all grooves for tankers and supply ships, or for engine room use where special drainage may be required.



The abrasive filler in the safe-groove tread section is of the approved type which has been tested for the Navy in accordance with the Bureau of Ships Standard Ladder Drawing No. 390599 Type J (Official Labortary Test, June 8, 1942).

Wooster combination ladder treads and deck treads have been approved by the Bureau of Ships, U. S. Navy Department. They have been subjected to severe tests for structural load carrying capacity and durability, and for the durability of the abrasive filler.

Wooster safe-groove ladder treads are made in standard widths of 4", 6", 8", 9" and 12", and in lengths 15", 16", 18", 20", 21", 24". Special sizes to order.

Pipe Joint Compound In Stick Form

Lake Chemical Co., Chicago, announces Pipetite-Stik, pipe joint compound in handy, clean, easy to use stick form. All that is necessary is to rub three or four strokes of stick across pipe thread. It spreads and fills threads when turned. Encased in a convenient cardboard holder, the stick may be carried around in a pocket or tool kit, always ready for instant use.

These are the features of Pipe-tite-Stik: it withstands gasoline, oil, butane, propane, Freon, air, water, steam, acid, gas, brine, sulphur dioxide; the joints can be disconnected easily months and years after applying; it lubricates and completely seals pipe joint threads, nuts, bolts, gaskets, turnbuckles; and it cannot flow into and clog even the smallest size pipes. It withstands vibration, temperature changes, deflection, pressure; and the joints can be remade without having to clean the threads. It also prevents rusting.

Plymouth Nylon Yacht Ropes

Yacht ropes, anchor lines and mooring lines made of nylon will be available to yacht owners this year, according to information released by the Plymouth Cordage Company of Plymouth, Massachusetts, the pioneers in nylon rope making. These synthetic ropes are being shipped to yacht supply houses for the 1946 season.

Yachtsmen will find these new nylon lines possess many distinct advantages, but perhaps the most outstanding are their extremely high tensile strength, resistance to rot and

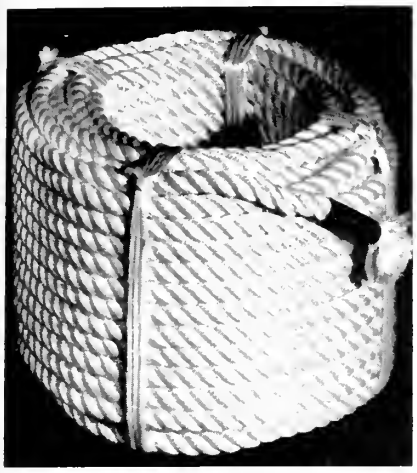
Nylon



marine decay, and exceptional elasticity and long life. Its rot-proof qualities permit it to be stowed immediately in a locker when wet.

In addition to these advantages, yachtsmen who have tested nylon rope during the past two years have found it easy to handle.

The superiority of nylon rope was proved during the war when it was used almost exclusively for tow-lines and mountain ropes. The company is now bending every effort to produce a large enough supply of nylon yacht rope for the 1946 season in view of the continuing scarcity of manila and linen lines and the heavy demand for fine ropes from boat owners whose lines have worn out and must now be replaced.

Great Salvage Job At Manila Bay

The greatest salvage job of the war was the clearing of Manila Harbor and the Subic Bay areas in the Philippines.

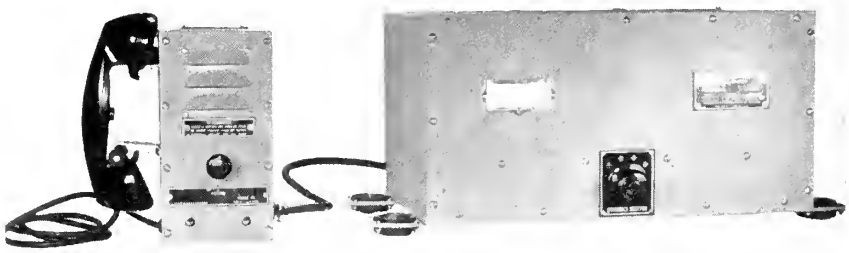
An estimated 650 wrecked vessels were found in Manila Bay and surrounding harbors, but within ten days the Army was enabled to continue landing supplies and within three months the port had been cleared of 350 vessels and was fully open.

Radiotelephone for Small Craft

Of interest to owners of small harbor and pleasure craft is the announcement by Radiomarine Corporation of America, New York, that its 1946 line of high quality marine radiotelephone equipment will include a combination radiotelephone transmitter and receiver, ET-8028. Operated from a 6 or 12 volt d.c. battery power supply system, this 10 watt instrument can be used on either of four transmitting frequencies which makes it particularly adaptable for service on the smaller power boats and harbor craft.

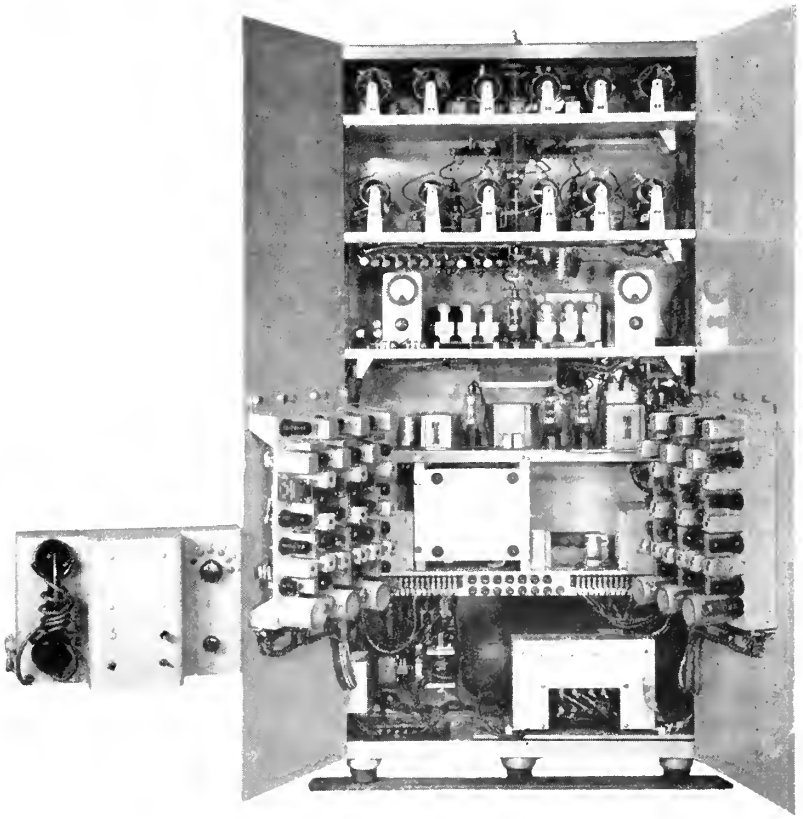
It has a good daylight range with correspondingly greater range at night. The receiver and transmitter are crystal controlled, a feature which enables the use of a single switch to place both transmitter and receiver on a desired channel. As in larger and more expensive sets, the ET-8028 is equipped with a remote control unit with standard telephone hand-set and built-in loud-speaker for use while waiting for calls. Despite its modest cost and compact size, this model has been designed with the usual RCA thoroughness for use under adverse sea and weather conditions. The overall dimentions are: height 13⅜ inches, depth 13⅞ inches, width 23⅝ inches, weight 40 lbs.

Radiomarine produces radio direction finders, radiotelegraph transmitters and receivers, automatic alarms, lifeboat radios, and will also produce new loran and radar navigational devices.



Above: Radiomarine radiotelephone, Model ET-8028.

Below: Model ET-8031, interior view. Radiomarine's new 75-watt radiotelephone with automatic remote control unit.



On the Ways — SHIPS IN THE MAKING

Left: STAR-SPANGLED SHIP—New luxury liner, Del Norte, made an impressive sight in this night scene taken just before launching at Ingalls Shipbuilding Corporation yards in Pascagoula, Miss. One of three sister ships, she is to be placed on the New Orleans - South American run by the Delta Line this spring.

Light Cruiser Fresno Now Afloat the Hackensack

The light 6,000-ton cruiser U.S.S. Fresno (CL121-Atlanta type cruiser) named for Fresno, California, took to the Hackensack River March 5, from U. S. Steel's Federal shipyard.

This was the last naval launching at the yard in 13 years of fighter shipbuilding, now largely replaced by commercial ship construction.

A bottle of champagne was bashed on the bow of the ship in the traditional christening ceremony just as she began to slide. The smashing blow was swung by the sponsor, Mrs. Ruth R. Martin, of Fresno. Mrs. Martin was chosen "Fresno's Mother of the Year for 1944."

The cruiser launched is the second ship to bear the name Fresno. The first was a naval overseas transportation ship which saw service in the First World War.

The vessel is the fifth "anti-aircraft" cruiser built by this shipyard. In addition to the original Atlanta, the others were the first Juneau, sunk in the same engagement as the first Atlanta; the second Juneau, commissioned February 15, and the Spokane.

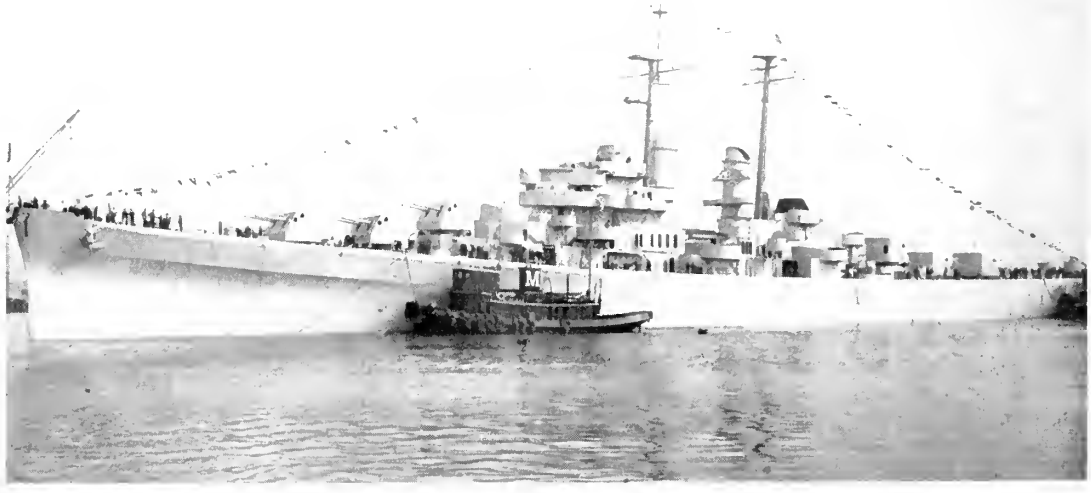
Major changes made since the original Atlanta was completed, include those in radar. The Fresno will carry 33 tons of radar equipment, consisting of seven distinct types operating 13 different sets. This will equip the cruiser to spot not only aircraft through fog, darkness, and beyond the horizon, but likewise surface ships, buoys, submarines, and land.

The ship's radar also will exercise fire control over the guns, thus insuring greater accuracy. All can be operated centrally by modern fire control and radar systems. It will find and destroy enemy craft while they still are out of sight.

The main battery consists of 12 five-inch guns in six turrets. Besides them, there are 32 guns of 40 millimeter calibre in 10 mounts and eight 20 millimeter guns. She is designed for a wartime complement of 47 officers and 706 men.

The vessel will be driven by two propellers, each 14½ feet in diameter, which will turn at the rate of 265 revolutions per minute at full speed ahead. They are connected through double reduction gears to high pressure steam turbines that develop a total of 75,000 shaft horsepower.

Steam at 600 pounds pressure per square inch will be generated by four oil-burning water tube boilers. Her fuel capacity is 1528 tons of oil. With this equipment, the Fresno should at least equal in speed the initial Atlanta, which recorded more than 33 knots on trials.



Cruiser Fresno (Atlanta Class, CL 121) took to the Hackensack River March 5.

FOR MECHLING BARGE LINE

Four new covered cargo barges leave Dravo Corporation's Neville Island Plant on their maiden trip to Joilet, Ill. The barges are 195' x 35' x 11' and feature nine watertight compartments in each hull.

Standard Acquires Tugs and Barges

Standard Oil Company of New Jersey has announced the acquisition of its own fleet for operation in the New York Harbor area with the purchase of six tugs and 19 barges with a carrying capacity ranging from 5000 to 30,000 barrels. Previously, the company contracted with outside carriers to transport all its products to its affiliates' terminals, dealers and consumers.

The acquisition of this fleet will enable the Standard Oil Company of New Jersey, largest supplier of fuel on the eastern seaboard, to improve further its service.

HER GUN PLATFORM REMOVED, her name again on her bow and in trim Socony-Vacuum colors, the veteran tanker Shabonee is converted.

New Grace Liner Santa Margarita Launched

With the launching of the new air-conditioned passenger and freight ship Santa Margarita on March 1, at the North Carolina Shipbuilding Company, Fred L. Doelker, vice president of Grace Line in charge on the Pacific Coast, has been advised by R. Ranney Adams, president, that this vessel, the third of the combination liners, will be placed in the New York and West Coast of South America service via the Panama Canal. This ship is the third to be launched. The previous two were the Santa Barbara and Santa Cecilia. These will operate in the same trade as the Santa Margarita, Doelker announced.

Like her eight sister-ships, now under construction or being fitted out for service, the Santa Margarita will accommodate 52 passengers.

All nine new Grace ships are of a modified C-2 type. Each displaces 14,945 tons, is 459 feet long, 63 feet wide and will carry 9000 tons of freight, including 100,000 cubic feet of refrigerated cargo.

Ship Warrants Act

Controls exercised over shipping by merchant ship warrants are still in effect despite termination of the United Maritime Authority agreement as of March 2, 1946, the War Shipping Administration states.

Public Law 173, Seventy-seventh Congress, commonly known as the Ship Warrants Act, as extended by Public Law 610, provides for the exercise of certain controls over shipping for six months after the termination of World War II shall have been proclaimed, or until such earlier time as the Congress or the President may designate.

Accordingly, until further notice, vessels are required, under the rules and regulations issued pursuant to the Public Laws involved, to hold valid United States merchant ship warrants to be entitled to priority in the use of shore facilities in United States ports.

OFF THE BOTTOM of New York Harbor and safely dry-docked after narrow escapes in two World Wars, the Brazilian ship SS Poconé is being repaired in U. S. Steel's Kearny, N. J. yard, to carry peacetime passengers and cargoes. Her stack and boilers had been removed for renovation before the photo was taken.

U. S. Navy tug Acoma, launched by the San Pedro yard of Bethlehem Steel Co. early in the year.

BETHLEHEM NAVY TUGS CHRISTENED

In a brief ceremony held February 21 at the Terminal Island shipyard of the Bethlehem Steel Co., shipbuilding division, Mrs. W. J. Courtiour christened the United States Navy tug Arawak. Miss Patsy Courtiour, her daughter, was maid of honor.

Mrs. Courtiour, wife of W. J. Courtiour, superintendent of repair for the San Pedro yard, in christening this vessel represented the repair forces of the yard, by whose efforts an average of two vessels per working day were repaired and returned to service during the war years with an enviable record for speed and quality of workmanship.

Above is the Acoma's sponsor, Mrs. W. A. Harrington cracking the traditional bottle of champagne at the christening.

U. S. Navy tug, YTB 702, christened the Arawak by Mrs. W. J. Courtiour with Miss Patsy Courtiour, maid of honor and Mr. W. J. Courtiour, superintendent of Repair, San Pedro yard.

The Arawak is the second of a series of four 100-foot, diesel-electric driven tugs of a new type designed for combination harbor and sea duty.

Oceangoing Tugs for Rescue Service

Allocation of three oceangoing tugs to the Navy Department for rescue service in the North Atlantic was announced by the War Shipping Administration on March 5.

Assignment of the 194-foot V4-M-A1 tugs will assist the Navy in carrying out salvage and rescue work which was being hampered by the lack of equipment and personnel resulting from the accelerated demobilization plans.

Launching at Consolidated

Pacing West Coast post-war shipbuilding, Consolidated Steel Corporation, February 19, launched the S. S. Carrier Dove at its Wilmington, California, shipyard. The Carrier Dove is the sixth vessel to be launched of a fleet of ten being built under contract with the U. S. Maritime Commission for assignment to private operators.

The big turbiner displacing 14,000 tons with an overall length of 460 feet and a beam of 63 feet and her nine sister ships are the largest merchant vessels ever built by a Southern California shipyard.

The big ship gayly painted, in contrast to the drab color of wartime-built ships was sponsored by Mrs. James E. Harvey, wife of Dr. J. E. Harvey, prominent Pasadena physician. Assisting the sponsor as matron of honor was Mrs. Norman L. MacLeod, Sr.

The launching of the Carrier Dove brought to 196 the parade of ships which have slid down the Consolidated Steel's ways into the waters of the Los Angeles-Long Beach Harbor.

The Carrier Dove was immediately towed to her berth at Consolidated Steel's docks where she joined four other ships of her class, the Spitfire, Ocean Rover, National Eagle and Mountain Wave for extensive outfitting.

The S.S. Messenger, first vessel built under the present peacetime contract by Consolidated Steel Corporation, was previously delivered to the States Marine Corporation of New York, via the U. S. Maritime Commission.

Guam Rounds Out First Year in Fleet

A year at sea may be the normal lot of a warship. But a great deal can happen during a year of warfare.

Veteran of some of the Pacific's most intense war patrols, the large cruiser Guam, recently returned to the West Coast with hundreds of Army and Navy personnel eligible for demobilization, and thus wound up, by this "magic carpet" assignment, her first year of active service with the Fleet.

Built by New York Shipbuilding Corporation and commissioned in September, 1944, the Guam and her sister ship, the Alaska, have been called "the American version of the pocket battleship." These two are the Navy's only large cruisers so far commissioned.

The Guam has an overall length of 808 feet, a beam of 89½ feet, and a displacement of 31,940 tons. Her armament includes nine 12-inch and 12 five-inch guns and a large number of 40 and 20-millimeter anti-aircraft guns. Her ship's wartime complement consists of some 125 officers and 2000 enlisted men.

Early in January, 1945, the Guam left the East Coast bound for the Pacific, enroute to Ulithi to join Task Force 58 in company with the carriers Intrepid, Franklin and Bataan and eight escorting destroyers. The Guam was assigned to operate with the carriers Yorktown, Intrepid, Enterprise, Independence, and Langley under the direct command of Vice Admiral A. W. Radford. On March 14, she sailed from Ulithi bound for the home waters of Japan. On March 18, she received her baptism of fire 70 miles off the island of Shikoku. Five Kamikaze attacks were made on the carrier force and escorts. The Enterprise and the Intrepid were hit, but the attacks were beaten off. The next day the carrier Franklin was seriously damaged by two 500-pound bomb hits that turned her into a blazing inferno. The Guam was detached from her group to protect the stricken carrier and escort her out of range of land-based aircraft.

When the Guam returned to home base after more than two months in enemy sea, her task group had destroyed over a thousand enemy planes.

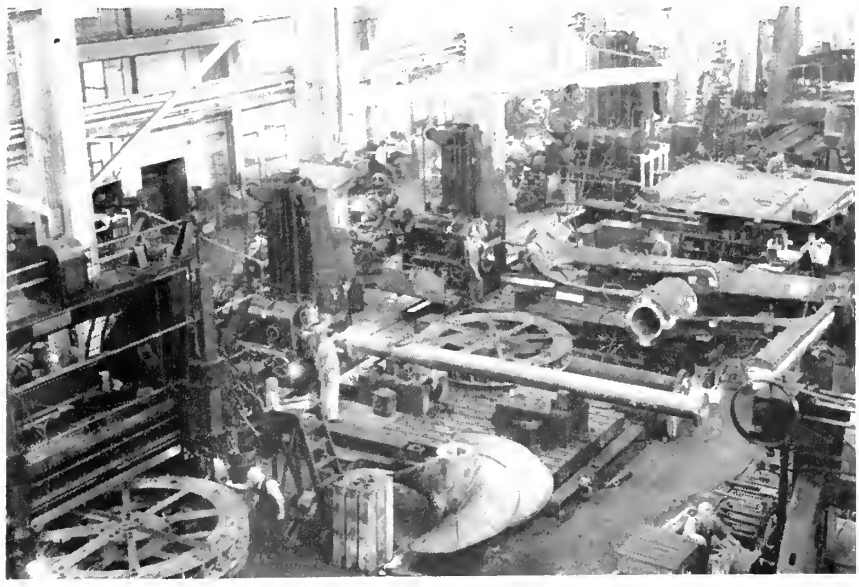
On May 24, the Guam sortied from Ulithi again, operating with two new fighting partners. Once again the Guam's unit was assigned to bombard a Jap-held island, Okino Daito, site of important Jap radar installations.

The Guam then sailed for the huge new fleet anchorage in San Pedro Bay in the Philippines. There she became the flagship of a new cruiser force, Task Force 95, under command of Admiral Francis S. Low, which proceeded to Buckner Bay, Okinawa, early in July. This force headed for Formosa, turned toward the China Coast and swung northward along the coast to Yungkia, 250 miles south of Shanghai. Then, it returned to Okinawa to complete an historic triangle.

When the war ended the Guam was made flagship of the North China Force under the overall command of Admiral T. C. Kinkaid, Commander, Seventh Fleet. For the next two months the Guam rested at anchor in Jinsen, the mightiest ship in the harbor and by far the largest ever to visit there. She left Jinsen on November 14, and reached San Francisco, December 3.

U. S. S. Guam, on patol prior to completing her first year stint with the fleet.

SHAVING SHIP'S PARTS AT FEDERAL SHIPBUILDING & DRYDOCK CO.



A group of boring mills in Federal's modern machine shop, machining parts for a C-2 cargo vessel: drilling flanges on line shaft; boring stern frame; and boring the rudder.

Design for Welding

(Continued from page 309)

ations. With such a system of weld identification any defect can be immediately traced to its source whether that source be plate edge preparation, welding technique or poor shipfitting.

With the wide spread use of radiography we had positive knowledge that each welded joint was capable of developing its designed stress without failure. Furthermore, we knew the quality of the welding that was being performed in the various shops and on the ways, and we could readily investigate any relaxation of the high standards of workmanship that we had adopted. We no longer had to deal with opinions as to whether the workmanship was satisfactory; our pictures were indisputable. There was no argument against a picture—especially when (as happened from time to time) the unsatisfactory weld was chipped out in the presence of the welder and his supervisor. The few non-believers soon learned that the film did not lie and that the only course to follow was that of careful workmanship and adherence to approved procedure.

In general the tendency was for the welders to improve the quality of their welding and to accept the evidence brought forth by the radiograph for what it was worth. Each welder realized that his work was subject to possible check. As a result he paid particular attention to plate edge preparation, realizing that the quality of his work depended on the quality of the work done before him; this in turn tended to improve the shipfitting itself. Each craft concerned realized that in radiography the inspection forces knew at whom to point the finger.

Our confidence in the standards established and maintained has been verified by an enviable absence of structural failures upon any of the vessels built by Marinship.

Industry's Stake In Shipping

(Continued from page 321)

with construction costs comparable to, and possibly lower than prices of our surplus ships.

Alternative: Lower Costs

But American ship operators aren't licked yet. They can cut the cost of handling cargo and the length of ship turnaround time in port. Cargo-handling costs are 30% to 50% of shipping costs. New efficiencies and technological advances are badly needed.

Perhaps much can be adapted from the Navy's new science of packaging and materials handling, including palletized loading. Large containers instead of a cargo-sling full of small packages offer possibilities, as do experiments with new types of cranes, booms, hatches. Loaded truck-trailers handled through side hatches might be feasible in the coastwise trade.

One worry to shipowners is the demand of maritime labor unions, both seafaring and dockside, for higher wages and shorter hours and their "feather bedding" rules.

Want International Pacts

These unions are now seeking international agreements to bring foreign maritime wages up closer to our rates. If this fails, ship operators hope the unions will see that the future of their jobs depends on making American ship labor, particularly in cargo handling, more efficient than foreign.

Less government regulation and red tape would help American ship lines. One line lists 36 government agencies it must deal with.

If American industry wants an American merchant marine it can help a lot by assisting ship operators in reducing cargo-handling costs; supporting government and private programs designed to foster our shipping; and, above all, "Shipping American."

Admiralty Decisions

(Continued from page 335)

was held that a Government employee might sue the Panama Railroad Company, wholly owned by the United States, should he so elect instead of accepting the benefits of the Compensation Act. Perhaps even more closely in point are cases involving suits by Government employees against the Director General of Railroads arising during the period of the First World War when the Government had taken over and operated the railroads under an act of Congress which gave the right to sue the Director General. In these latter cases it was held that the compensation act was not the exclusive remedy of the plaintiffs. In **Payne, Director General** vs. **Cohlmeyer,** (275 Fed. 803 7th Circuit) a deputy marshal of the United States was allowed to maintain a suit for injuries, the court saying, "While an employee may elect to take under this Compensation Act he is not required to do so." And in **Dahn** vs. **McAdoo, Director General,** (256 Fed. 549 (DC Iowa), 267 Fed. 105, 258 U. S. 421), it was likewise held that a United States railway mail clerk who sustained injuries as a result of alleged negligence on the part of the Illinois Central Railroad could maintain such a suit, although in the particular case his prior acceptance of benefits under the compensation act was held a bar.

There are certain cases, however, that do not support the contentions of respondent in this case; namely, **Dobson** vs. **United States,** (1928 A. M.C. 1583, Second Circuit), and **Bradey** vs. **United States,** (1945, A. M.C. 1329, Second Circuit). Each of these cases, however, involved the Public Vessels Act.

The Court's opinion points out, in addition to the above, that the recent **Brady case** handed down by Judge Learned Hand has certain language that might be turned around to stand for the propositions advanced by the respondent. However, the Court quite correctly concluded that Judge Learned Hand did not intend for such a result to follow. As previously stated, the exceptions to the libel were therefore overruled. The libellant will therefore be permitted to continue his case upon the merits under the Suits in Admiralty Act.

Below, left: Closs-room instruction at USMS Officers' School at Alameda.

Captain Malcolm E. Crossman, USMS, superintendent of the United States Maritime Service Officers' School, Alameda, California, was luncheon host to a group of San Francisco Bay Area editors and publishers on March 13.

Among those present were: A. Kofman, publisher, Alameda Times-Star; Colonel Thor Smith, associate publisher, The San Francisco Call-Bulletin; Joshua Eppinger, executive editor, The San Francisco Examiner; W. D. Chalmers, associate publisher, The San Francisco Chronicle; H. J. Debenham, assistant circulation manager, The San Francisco News; G. W. Roe, managing editor, The Oakland Post-Enquirer, Raymond Lawrence, feature columnist, The Oakland Tribune; B. N. DeRochie, assistant publisher, The Pacific Marine Review, and Pat Martin, editor, The Log Magazine.

The newspaper and magazine executives were given a personally conducted tour of the School by Captain Crossman and his ranking officers. This included life saving demonstrations in the station swimming pool, visits to class rooms with actual demonstrations of the work being accomplished, and movies of the station activities. At 1600, after a busy af-

Occasion of New Location in

At top, left: George E. Swett, Mr. and Mrs. Herbert E. Foster and Mrs. Swett.

A striking tribute to the popularity of George E. Swett, head of the firm of George E. Swett & Company, engineers, was the response of over three hundred men of San Francisco's ship operating, shipbuilding and allied maritime industries to come aboard for the Open House which dedicated new quarters of the marine and industrial supply firm at 256 Mission Street on March 15.

The new building gives the Swett organization approximately 20,000 square feet of space for storage, sales and executive offices and departmental functions.

This firm is ready to offer ship owners new equipment and reconversion service immediately. Such equipment includes refrigeration, air-conditioning, steam pumps, valves, blowers, governors, deck machinery, steering gears, thrust and journal bearings, fans, propellers, soot blowers, gages, heat exchangers, packing, porous stone filters, safety valves, recording instruments and others.

The engineers will occupy all but a few feet of the ground floor of

Open House—San Francisco

their building. The basement will house heavy storage, including pumps, blowers, motors, along with many spare parts. The first floor will be used as a display room and for light storage. On the second floor are the executive offices, service department and light repair shop. The engineers and draftsmen will occupy all of the third floor.

At the present time there are 52 employees, under the direction of George E. Swett, who started the firm in San Francisco in 1920. L. A. Stone is assistant general manager; W. J. Kinney, manager of service department; H. N. Craig, purchases and stores; Major J. E. Swett, service engineer; Robert W. Long, sales engineer; Henry Guilmette, sales engineer; William Pullen, sales engineer; Walter Keats, chief storekeeper; R. E. Estes, auditor, and Doris C. Southworth, cashier.

George E. Swett's family were shipbuilders on the Penobscot River and constructed some of the famous marine clipper ships. It was there that young George grew up learning to like vessels that sail the seas. Off at the University of Maine George studied electrical engineering, and upon graduation served for ten years with the General Electric Company in their testing, engineering and sales departments. During the last years with GE he collaborated with Allan Cunningham of Seattle, pioneer marine auxiliary designer and manufacturer of original designs of electric

NEED FOR CONCERTED ACTION TOLD

The need for cooperative action by the shipping industry in the fields where their interests are mutual and non-competitive was stressed by Barrister Gregory Harrison in his talk "What Lies Ahead for American Shipping" at the San Francisco Propeller Club in February.

Harrison defined these fields as those of public, government and labor relations in a meaty talk which presented the problems—and a few advantages—of the present situation.

Among the latter are those of public sentiment in favor of foreign trade and a strong merchant marine, and the government's orderly approach to ship disposition.

He closed by pointing out that Pacific Coast shipping has been a leader in common approach and its future lies in the continued exercise of cooperative action.

President Joe Geary introduced the new members for February: Ralph E. Crosby, chief electrical draftsman, Bethlehem Steel Co., Shipbuilding Division; Richard D. Karr, chief, technical section, War Shipping Administration; Lt. Comdr. Kenneth R. Madison, USNR, faculty advisor for Propeller Club, U. S. Merchant Marine Cadet School, San Mateo, California, and W. J. Williams, superintending engineer, Matson Navigation Company. Former members reinstated after tour in the service were: Oscar J. Beyfuss, Ship's Agent; and George P. Bradford, De La Rama Steamship Company.

Left to right: Gregory Harrison, Joseph J. Geary and Albert W. Gatov.

Pacific MARINE REVIEW

NEWS FLASHES

NEW 650 ft. PASSENGER AND CARGO VESSELS READY FOR BIDDING.

The Maritime Commission has called for bids to be opened on April 15, for three 650 ft. twin screw turbine-driven passenger and cargo vessels of the Commission design P3-S2-DL1. These ships are intended for the American Export Lines' Mediterranean trade and will have a speed of 22 knots. The bid opening was originally planned for March 18, but is now scheduled as above.

* * * * *

BID OPENING SCHEDULED FOR 670 ft. PASSENGER LINERS.

On April 25, the Maritime Commission will open bids for two 670 ft. twin screw turbine-driven passenger liners of the Commission design P3-S2-DA1. These ships are intended for the East Coast South American route and will have a speed of 28 knots. These liners will be the fastest merchant vessels ever built in the United States. The bid opening was originally scheduled for March 28th.

* * * * *

QUALIFICATIONS FOR BIDDERS UNDER MARITIME COMMISSION PROCEDURE.

The Maritime Commission may require information of any kind it deems material in deciding a bidder's qualifications and responsibility. He must possess the ability, experience, financial resources, and equipment necessary to properly perform the contract. Bids must be accompanied by a guaranty in the sum of $50,000. to assure the execution of the contract and the surety bonds required thereunder. No bids may be withdrawn after they have been opened.

Use of Government owned shipyards.

In cases where the shipyard is entirely government owned, the value of its use will be deemed to be 3½% of the bid price. In the event that the shipyard facilities are partially government-owned, the number of shipways built or rebuilt at government expense will be the determining factor. However, any shipways that will be in excess of the bidder's needs after August 30, 1946, may be excluded. The status of all yards was determined on February 18, 1946, and will be published in the Federal Register at least five days prior to the opening of bids.

* * * * *

SUN SHIPYARD LOW BIDDER ON ORE CARRIERS.

The Sun Shipbuilding and Drydock Company was low bidder for the proposed construction of four 560 ft. single screw turbine-driven dry bulk cargo vessels, 16 knot speed, type C5-S-AX1, designed for use of the Ore Steamship Corporation, New York. Bidding was as follows:

Sun Shipbuilding and Drydock Company,	$4,748,000, delivery in 390, 420, 450, and 480 days.
Bethlehem-Sparrows Point,	$4,900,000, delivery in 260, 305, 395, and 456 days.
Newport News Shipbuilding Company,	$6,750,000, delivery in 420, 465, 510, 555 days.

DIESEL POWER SURPASSES STEAM ON INLAND RIVERS.

During the year 1945 Diesel propulsion which started from scratch barely 20 years ago surpassed steam on the Nation's 13,000 miles of inland waterways. As of December 31 last, 60% of the total available h.p. on the 1125 vessels principally engaged in shallow water commerce was Diesel. New vessel construction has been very largely Diesel and most power replacement programs have been in the same category.

* * * * *

MATSON BUYS PLANE FOR HAWAII FLIGHTS.

A four-engined Douglas DC-4 airplane, soon to fly between the Pacific Coast and Hawaii chiefly in connection with Matson's air transport division in San Francisco has been purchased by the Matson line. The air transport division is now converting and overhauling various aircraft for civilian use and a company plane is necessary for transporting personnel and equipment where time and speed are important.

* * * * *

PRIVATE VESSELS MAY SOON CARRY ARMY AND NAVY CARGO.

The War Shipping Administration's policy and that of the Maritime Commission is to return to private operators as fast as possible, and in so far as possible, all ocean freight movements. Since the Army and Navy will probably have returned nearly all merchant type vessels operated by them during the war period back to WSA by July 1, 1946, it appears likely that a high percentage of all Army and Navy cargoes will be handled by private vessels after July 1.

* * * * *

U.S. TO IMPORT 5,000 BALES OF JAPANESE RAW SILK.

The RFC announced on March 8, that it would bring 5,000 bales of Japanese raw silk to this country shortly and follow with regular shipments as soon as possible. The U. S. Commercial Corporation, RFC subsidiary, will import the silk under arrangement with General MacArthur and the War Department, and sell it in this country under sealed bids.

* * * * *

MOORE DRY DOCK COMPANY GETS BIG CONVERSION JOB.

Contracts for the reconversion of the troopship General M. C. Meigs and General W. H. Gordon have been awarded to the Moore Dry Dock Company of Oakland. The Yard's bid was $454,382. for the two vessels, which are of the P2-S-2-R2 type. The ships will be used on the Oriental run by the American President Line. The transports were built by the Federal Shipbuilding Corporation of Kearny, New Jersey, and accommodated 5,000 troops. They are 622 feet in length, 75 feet beam, and have a speed of 20 knots. Tonnage is 5,000 deadweight. These will be the first large passenger liners to be turned back to West Coast private operators.

* * * * *

BIG HARBOR JOB AT SAN DIEGO.

The Army Engineers have completed their recommendation for a flood control and navigation project at Mission Bay, San Diego, that will total $14,680,000 figured on a pre-war basis. The job involves flood control improvements on the San Diego River, alteration of a railroad bridge, construction and alteration of highway bridges, utility relocations, and drainage structures. Navigation improvements in Mission Bay include dredging, filling, stone jettys, levees, small craft moorings and floats, removal and construction of highway bridges, sheet pile bulkheads, and land acquisition.

The project will be charted and described further in the May Pacific Marine Review.

BIDS OPENED ON RECONVERSION OF PRESIDENT POLK.

On March 25, the Maritime Commission office in San Francisco opened bids for the reconversion of the American President Line's round-the-world liner President Polk. Low bidder was the United Engineering Corporation followed by Todd's Los Angeles yard, Moore Dry Dock Company and Bethlehem's local yard. There were various conditions attached to some of the bids and the award will be made in Washington.

A second APL pre-war round-the-world vessel will be up for bids during April. This is the President Monroe. Both the Polk and Monroe are C3 type vessels and will be used on the Orient run from San Francisco.

* * * * *

AMERICAN PRESIDENT LINES ROUND-THE-WORLD SERVICE.

The famed round-the-world service inaugurated by Robert Dollar will consist of freighters only, for the next several years. C4 type of vessels will be used. The P2s, C2s and prewar C3s will be used in APL's other services.

* * * * *

NEW CEILINGS FOR SHIP CHANDLERS.

Dollar and cent ceiling prices, exactly as requested by WSA, have been established for sales by ship chandlers to vessel operators by the OPA. The ceilings, which were effective March 25, are listed for 75 different commodities, or groups of commodities, and include most of the items sold by ship chandlers to merchant vessels for subsequent resale to vessel personnel.

* * * * *

FIVE HUNDRED LEASED SHIPS RETURNED BY WSA.

Over five hundred vessels under charter to the WSA during the war have been returned to their owners here and abroad. A report of the division of re-delivered chartered vessels shows 322 tankers, five passenger ships, three barges, one cable vessel and 171 dry cargo ships. The reason for the preponderance of tankers lies in the fact that their return began last Fall.

* * * * *

FIFTY LIBERTY SHIPS TO ITALY.

The Italian Government has announced that its Trade Mission in the United States has arranged for the purchase of 50 Liberty ships from the Maritime Commission for a total of $24,000,000.

* * * * *

JOSHUA HENDY BUYS WAR BUILT FACILITIES AT ITS PLANT.

Subject to the approval of the War Assets Corporation, the Maritime Commission has approved the sale to the Joshua Hendy Iron Works, Sunnyvale, California, of all government-owned war built facilities at its Sunnyvale plant.

The Commission will accept the Hendy offer of $565,500, pay a $2,925,000 mortgage held by the Commission and assume all the Commission's liabilities at the plant. Government facilities there cost some $5,571,000.

The Hendy Company built power equipment for merchant vessels during the war and made many specialized military devices.

* * * * *

BRITAIN'S LAUNCHING RECORD.

Cargo liners are being launched in Britain's shipyards at the rate of one a week. By the end of the year, one a day will be gliding down the ways. The all-welded construction used on many U. S. vessels has been rejected in England in favor of the normal riveting and part-welding.

SWEDISH-AMERICA LINE ORDERS LORAN UNITS.

An initial commercial order for 17 electronic long range position finders capable of a navigational "fix" in from two to seven minutes under any weather conditions at off-shore distances of from 750 to 14,000 miles has been placed by the Swedish-America line with the Sperry Gyroscope Company.

* * * * *

TUGS FOR HAWAII.

The Hawaiian Pineapple Company has awarded contracts for the construction of two 145 ft. ocean going tugs to the Bath Iron Works Corporation. The vessels will be used in transporting fresh pineapples from the plantations on the island of Lanai to Honolulu, an 80 mile haul, and will also be equipped to handle all types of heavy duty deep-sea towing. They were designed by W. C. Nickum and Sons, naval architects of Seattle.

* * * * *

PACIFIC COAST SHIPYARDS LED COUNTRY IN 1945 PRODUCTION.

As in each of the war years, the Pacific Coast shipyards completed in 1945, the largest percentage of the total number and tonnage of merchant vessels built by all yards throughout the country, finishing 454 vessels of 3,485,000 gross tons. Atlantic Coast yards delivered 324 vessels of 2,533,000 gross tons, Gulf yards 235 vessels of 1,439,000 gross tons and Great Lakes yards, 54 vessels of 205,000 gross tons, all of which were of the Cl-M Diesel-propelled type. For the fourth successive year the State of California led the country in producing merchant vessels, turning out 330 or almost 1/3 of the total completed in the United States. The State of Oregon was second with 111 vessels. The large merchant ships completed in 1945 were produced by 39 shipyards.

* * * * *

TABULATION OF PROPELLING MACHINERY IN 1945 PROGRAM.

The types of propelling machinery installed in merchant ships of over 2,000 gross tons in 1945 were as follows:

Geared turbine	492	ships	3,811,450 h.p.
Turbo-electric	188	"	1,424,980 h.p.
Reciprocating	147	"	366,000 h.p.
Diesel	214	"	361,950 h.p.
Total	1,041	"	5,964,380 h.p.

The h.p. of propelling machinery installed in large merchant ships during the 7 war years totalled 23,073,558. Almost one-half of this total is made up of geared turbines amounting to 10,459,340 shaft h.p., followed by turbo-electric which totalled 7,108,500.

* * * * *

NEW DRY DOCKS AT SEATTLE.

The Puget Sound Bridge & Dredging Company of Seattle is reported to be planning the construction of four dry docks for ship repair work at an estimated cost of $5,000,000 for its own account.

* * * * *

JAPS LAUNCH TRAIN FERRY.

A 4000 ton train ferry, the first Japanese ship to be launched since the cessation of hostilities, has been launched in the Port of Uraga with 8th Army representatives on hand to witness the event.

* * * * *

C & H SUGAR REFINING CORP. TO BUILD AT LOS ANGELES.

The California & Hawaiian Sugar Refining Corp. has acquired 5 acres in Los Angeles for the ultimate installation of a sugar refinery. Temporarily a distribu-

tion station for tank truck delivery of liquid sugar products will be established. W. R. Junk will manage the plant.

* * * * *

SHIPYARDS TO BE RETAINED BY NAVY AND USMC.

The Surplus Property Administration in its recommendation to Congress asked that 13 privately-owned yards and 29 additional new units be retained in working order for purposes of National Defense.

The Navy plans to hold in commission 25 new yards, and facilities belonging to the government in twelve private yards. The Maritime Commission plans to retain 4 new yards, and facilities in one privately-owned yard. With this program the Surplus Property Administration is apparently in accord.

* * * * *

MARITIME COMMISSION ESTABLISHES RESERVE FLEET DIVISION.

The Reserve Fleet Division of the Maritime Commission is announced to have charge of the acquisition and maintenance of all vessels not needed in the operation of the post-war merchant marine but required by national security. Its functions will be those of a like division of the War Shipping Administration, and also include the handling of all matters relating to survey, acquisition, development and maintenance of sites where vessels are placed in temporary or permanent reserve fleets.

The acting director of the new division is Frank E. Hickey; assistant director is Ernest W. Gorman.

* * * * *

NEW COMPANY IN VANCOUVER.

Western Canada Steamships Ltd. is a four-company shipping organization being formed in Vancouver, B. C., to purchase a fleet of 12 to 20 freighters. The firm will operate on deep sea lanes in general British Columbia trade. The vessels are of the Canadian and Victory types, 10,000 tons, and will cost $575,000 each.

* * * * *

ALUMINUM SHIPS.

The Aluminum Company of America is reported to have placed orders with two naval architects in New York for the design of two all-aluminum vessels for Alcoa's Caribbean service.

* * * * *

SHIPYARDS IN NON-MARITIME WORK.

Although all operating shipyards have or will soon have backlogs of repair and conversion work that will carry them for from one to five years, some yards are proceeding to develop departments for handling non-maritime business. Bethlehem and Consolidated in California have elaborate programs in structural steel production and so have many others. An announcement is just made from the Moore Dry Dock Company, Oakland, that long standing orders for industrial work of all types may now proceed. In addition to steel for bridges and buildings the company specializes in roll grinding, roll corrugating, mill and coffee rolls and roller bearing barley mills. Ingalls is going in for Diesel electric locomotives; and many yards have plans for reaching foreign buyers of industrial equipment, as well as for ships, barges and smaller craft.

* * * * *

REMITTANCES ABROAD ARE INCREASING.

During 1945, Americans and foreigners residing in the United States made remittances estimated at more than $300,000,000 to friends and relatives abroad, chiefly in Europe, Latin America and China, and the prospect is that these remittances will increase sharply in the next few years. This will be good news for foreign traders for it sets up an exchange balance that will aid the export market.

Before the war in 1939, such personal remittances of a non-commercial nature totalled $144,000,000, but they dropped to a new low of $100,000,000 in 1942.

TUGS FOR RUSSIA.

The Marietta Manufacturing Company, Point Pleasant, West Virginia, has a contract for construction of 6 steel ocean going tugs for the USSR. Each tug is to be 140 ft. long, 32 feet beam and 18½ feet deep with Skinner Unaflow marine steam engine developing 1200 h.p.

* * * * *

FRENCH SHIPS ORDERED IN VANCOUVER.

The Burrard Drydock Company, Vancouver, B. C., has a contract for construction of ten large coal carrying ships for the French Government to cost between twelve and fourteen million dollars. Five vessels are to be of 7500 tons and five of 5000 tons.

* * * * *

FRENCH ORDER DIESEL TRAWLERS.

The Bath Iron Works has a contract from the French Government for 32 Diesel propelled trawlers. Twenty of these are to be 117 ft. long, 22½ ft. beam and 12 ft. 9½ in. deep, with Burmeister and Wain Diesel engines developing 450 h.p. Six trawlers are to be 223 ft. long, 38½ ft. beam, and 20 ft. 8 in. deep, with Burmeister & Wain Diesel engines developing 1100 h.p. Six trawlers are to be 152 ft. long, 27 ft. beam and 15 ft. 5 in. deep. These will have De La Vergne (Baldwin Locomotive) Diesel engines developing 750 h.p.

* * * * *

ALUMINUM ORE CARRIERS.

Gibbs & Cox, New York, are reported to be preparing plans for 3 aluminum-ore-carriers 350 ft. long, for the Aluminum Company of America.

* * * * *

UNITED FRUIT.

The United Fruit Company is planning the construction of two passenger cargo ships with accommodations for 125 passengers. These are in addition to nine cargo passenger ships now under construction in the Bethlehem Sparrows Point Shipyard. The two new vessels are reported to be planned for 6400 deadweight tons and a 19 knot speed.

* * * * *

CANADIAN NATIONAL STEAMSHIP COMPANY.

Plans are in preparation by a Pacific Coast naval architect for two new ships for the Canadian National Steamship Company, Vancouver, for service between Victoria, Vancouver, Prince Rupert and Skagway. It is possible that the ships may be built in Pacific Coast yards but the Canadian Minister of Transport said that the cost would be 35% to 40% higher than in Great Britain and construction of the Pacific Coast would depend on the obtaining of a government subsidy to take care of the difference.

* * * * *

MARINE PAINT EXCLUDED FROM LINSEED OIL QUOTA.

The Secretary of Agriculture announces an amendment to War Food Order No. 42a that has the effect of excluding from the distribution quota all linseed oil used in marine paints when such paint is to be delivered to the Maritime Commission or W.S.A. The manufacturer must claim the exemption however on Form FDO 42-4.

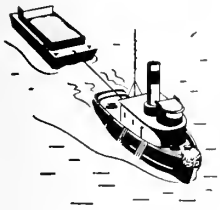
The supply of linseed is still tight. This week a representative of the Department of Agriculture now in Buenos Aires purchased for the United States the entire exportable surplus of Uruguay - some 4,000,000 bushels of linseed - which amounts to about 1300 tank cars of oil.

He is also expected to get a good share of the 25 to 30 million bushels available in Argentina. Other nations will participate in the Argentina distribution, however.

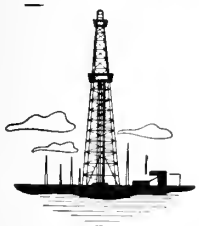
Cordage FOR EVERY PURPOSE

MANILA ROPE — **The availability of "AMERICAN BRAND" PURE MANILA ROPE in the immediate future, will depend upon (1) government restrictions which may exist, such as CPA Order M-84 and (2) the amount of first grade Manila fibre obtainable. As long as our output of "AMERICAN BRAND" PURE MANILA ROPE is limited, we will distribute what we have just as fairly as possible.**

Ship's Cordage is made with careful manufacturing attention to the specific requirements of the ultimate use, a fact responsible for the wide preference for "AMERICAN BRAND" ROPE.

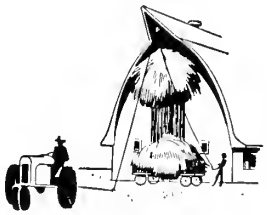


"AMERICAN BRAND" Tow Lines and other work boat cordage are made from long experience in deep sea, harbor and inland waterway requirements. Large quantities of "AMERICAN BRAND" ROPE are bought by fabricators for conversion into bumpers, nets, slings and ladders.



In the oil fields, "AMERICAN BRAND" is the accepted standard of top-quality in Drilling Cable, Crackers and Spinning Lines. In all industry, "AMERICAN BRAND" is the guide to quality cordage.

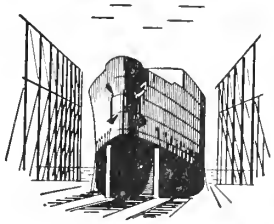
Twines of every description both hard and soft fibre and polished, are produced under "AMERICAN BRAND." For express packages, bundling of all kinds . . . for office, store, or home, "AMERICAN BRAND" TWINES are always uniformly strong...always dependable.



For farm and ranch use, "AMERICAN BRAND" ROPE provides exceptional resistance to heat, moisture and abrasion. It is ideal for haying. Lariat Rope is a specialty.

Lumbering is but one of many rugged industries which place heavy responsibility on cordage. "AMERICAN BRAND" ROPE is made to rigid requirements for materials and workmanship. You can count on its being top quality always.

"AMERICAN BRAND" fisherman's cordage has received special attention to assure maximum service life in spite of the repeated salt water soakings and drying out in wind and sun.



Shipbuilding and ship repair work consumes enormous quantities of "AMERICAN BRAND" Marine Oakum and Marline, as well as Rope. Industrial contractors use "AMERICAN BRAND" Plumbers Oakum and Twisted Jute Packing for sealing the joints in water and gas mains.

AMERICAN CORDAGE PRODUCTS

"THE SHIPPING OUTLOOK"

Gleanings from the address of R. V. Winquist, vice president of General Steamship Company, in his talk before the Mariners Club of San Francisco on March 6:

"The post-war situation in shipping is presenting many a headache. We have under the American flag nearly half of the world's tonnage and about three times as much as we had before the war. In 1939 there were 75 million tons in the world – 11 million tons under the American flag. Today there are about 95 million tons – 55 to 60 million tons under the American flag. We have increased our shipping by five times, while the rest of the world has lost about one-half. It is not a very healthy picture.

"Before the war we handled 30% of our overseas trade with 3,300,000 tons; to handle 50%, as urged by many, it is estimated that we shall need 5½ million tons. After allowing for domestic operation, we have to absorb 9½ million tons in overseas trade if we reach the 16 million tons total. This 50% goal seems beyond reach in the trade between the Pacific Coast and Europe.

"The Ship Sales Bill provides for sale of all ships to and operation by private interests. They will be first sold to Americans on easy terms and the leavings in ships to be available to foreigners. It has been estimated that we can sell between 7 and 12 million tons to our allies.

"There will be plenty of shipping in the post-war world. British and other European yards are already busy turning out specialized types. And there are nearly 4600 ships available for sale. No matter how they are divided between American and foreign buyers, it is evident that our foreign trade transportation needs will be provided."

Above—At end of table: Joe A. Benoit, Marine Instrument Company; Charles Halpern, West Coast manager, Gotham Instrument Company; G. O'Toole, Matson Construction and Repair, Purchasing Department; and C. H. Peabody, Marine Instrument Company.

Head table guests—Dick Glissman, Frieda Salzman, Red Cross guest; Captain Raymond Demarest, S. Christy, and Felix V. Billig.

Bon Voyage

WITH THIS G-E CREW ABOARD

The G-E Line of Marine Refrigeration Equipment Includes:

Marine Compressors and Condensing Units
Freon-12 Condensers and Receivers
Cooling and Heating Coils
Direct Expansion Coils
Self-Contained Storage Cabinets
Remote Storage Cabinets
Conditioned-Air Cooling Units
Drinking Fountains and Water Coolers
Air-Cooled Condensing Units
Refrigeration Controls
Co-ordinated Marine Equipment

LEADING MARINE ENGINEERS and ship builders take no chances with refrigeration failure.

The ships they design and build steer clear of cargo spoilage or discomfort to passengers and crew. More and more ship specifications call for G-E refrigerating equipment . . . Navy-proved under the most severe conditions.

G-E equipment is available for every maritime refrigerating and air conditioning need. Write today giving details of your specific problems. We'll be glad to help. *General Electric Company, Air Conditioning Dept., Section 6594, Bloomfield, New Jersey.*

Marine Refrigeration

A SHIPPING COMMISSIONER'S LEGAL BASIS

As early as 1790 the First Congress of the United States enacted a law requiring the master of every vessel bound on a foreign voyage, and of every vessel of 50 tons burden or upward bound from a port in one State to a port in any other than an adjoining State, to make a written agreement with each member of his crew declaring the nature and duration of the voyage.

Later it was found that seamen needed additional protection from the risks of being carried on long voyages without fair agreements, and in 1872 an act was passed, patterned after the British law which had been in effect for about 18 years, providing certain minimum particulars which the agreements, or articles, for foreign voyages were required to contain, and providing for the supervision of certain matters relating to the agreements by a Government official called a shipping commissioner. The law authorized the appointment of a shipping commissioner for each port of entry which is also a port of ocean navigation, and specified five general duties of a shipping commissioner, only two of which remain important today because of changed conditions. They are: (1) to superintend the engagement and discharge of seamen in the manner prescribed by law, and (2) to perform such other duties relating to merchant seamen or merchant ships as may be required by law.

Under existing law the crews of vessels bound on foreign voyages, other than those to the British North American possessions, the West Indies, or Mexico, and the crews of vessels of the burden of 75 tons or upward bound on intercoastal voyages, sign the required agreement with the master in the presence of a shipping commissioner. It is the duty of the shipping commissioner to see that each seaman is made acquainted with and understands the conditions of the agreement and that he does not sign it involuntarily or while intoxicated.

In the case of agreements signed before a shipping commissioner the law declares that the agreement must be, as near as may be, in the form which is set out in the law and requires certain particulars which the agreement must contain.

The agreement must state the nature and, as far as practicable, the duration of the intended voyage or engagement and the port or country at which the voyage is to terminate. This requirement has been waived during the war, however, provided a certain standard general description is used. The agreement must also describe each crew member and specify his employment, give the time at which each seaman is to be on board to begin work, state the capacity in which each seaman is to serve and the amount of wages which he is to receive.

A scale of the provisions to be served to each seaman must be included in the agreement. The form of agreement incorporated in the law specifies a minimum scale, although a higher scale could be used if agreed upon by the master and crew.

The parties to the agreement may also agree to adopt regulations as to conduct on board, and as to fines, short allowance of provisions, or other lawful punishment for misconduct, which may be sanctioned by Congress or authorized by the Secretary of Commerce not contrary to or not otherwise provided for by law.

Any stipulation in reference to advance and allotment of wages must be entered in the agreement, and other matters not contrary to law which are agreed upon may also be entered.

Shipping commissioners may ship crews for vessels in the coastwise trade, and other trades for which crews are not required to be signed on before a shipping commissioner, if requested to do so by the master or owner of the vessel. In the event a shipping commissioner does sign on a crew for a vessel in one of those trades, the same rules apply as when a crew is shipped for a foreign voyage, except that the agreement does not include a scale of provisions, stipulations in reference to advance and allotment of wages, and other matters not specifically required by law.

By statute it is made lawful for any seaman to stipulate in his shipping agreement for an allotment of any portion of the wages he may earn to certain specified allottees. No allotment, however, is valid unless made in writing and approved and signed by the shipping commissioner. It is the duty of the shipping commissioner to examine all allotments and the parties to them and to enforce compliance with the laws governing them.

Every seaman shipped before a shipping commissioner must also be discharged and receive his wages before a shipping commissioner if he is discharged in the United States. Upon completion of the discharge and settlement the master or owner and each seaman are required to sign a mutual release of all claims for wages on the past voyage, and the shipping commissioner must also sign and attest the release provided both the master and seaman assent to the settlement, or it has been adjusted by the shipping commissioner.

Upon the discharge of any seaman and payment of his wages, the shipping commissioner is required to enter in the seaman's continuous discharge book, or in a certificate of discharge if the seaman carries a certificate of identification instead of a continuous discharge book, a record of the length of employment on the particular voyage. The record contains a short description of the vessel and voyage and the name and rating of the seaman but must not contain other entries.

It is also provided by law that every shipping commissioner shall hear and decide any question whatsoever between a master, consignee, agent or owner and any member of his crew which both parties agree in writing to submit to him. Awards made thereunder are binding in any later legal proceedings.

Whenever any seaman belonging to or sent home on any merchant vessel engaged on a voyage which is to terminate in the United States dies during the voyage, the master takes into possession his effects. If the first port touched by the vessel is a port in the United States, the master must deliver the effects and wages due the deceased to the shipping commis-

(Proceedings Merchant Marine Council, United States Coast Guard.)

sioner, together with an account in the form which the shipping commissioner may require. It is the duty of the shipping commissioner to examine the account, and if the applicable provisions of law have been complied with, to grant the master a certificate to that effect. Within 1 week after receiving the effects of a deceased seaman the shipping commissioner is required to deliver them to the district court for distribution.

The effects and wages of deserting seamen are forfeited by law, and the procedure for their disposal is somewhat the same as that for the effects of deceased seamen. The master delivers the effects and the balance of the wages after the expenses occasioned by the desertion are paid to the shipping commissioner in the port at which the voyage terminates. It is his duty to account for and pay over the balance to the district court within 1 month after its receipt.

Fog Dispersal Burner

The development of a new type of burner for the dispersal of fog on airfields, using diesel fuel oil instead of more expensive low octane gasoline, was recently announced by the Babcock & Wilcox Company, exclusive designers of the equipment.

The company's system, recently demonstrated to the public for the first time at the Naval Auxiliary Air Station at Arcata, Calif., has far-reaching implications for the future of "FIDO" (Fog, Intensive, Dispersal, Of) both for the Army and Navy, and the commercial airlines. In addition to burning cheaper fuel, the new system represents several other improvements over earlier equipment, which was developed largely in England, where in 1943-44 it helped keep allied bombers in non-stop operation and saved many lives and planes that would otherwise have been lost due to intense fog. The firm of Babcock & Wilcox, Ltd., of London, England, was responsible for the development and construction of one of the early British burners.

The B & W system was developed in this country. Its burners may be installed with a minimum of disturbance to the existing airfield and a minimum of obstruction to aircraft operating on the field. Instantaneous combustion or rapid stopping of burner operation can be achieved, since the burners are ignited electrically at will from the control tower. Furthermore, the ignited burners burn with a bushy flame of an intense heat with complete combustion, and give off a minimum of smoke while in actual operation or in starting up or shutting down.

Another important feature of the B & W system is that it atomizes rather than vaporizes the fuel to prepare it for proper combustion. Drawing on a large background of experience in the development of oil burners for Navy and marine boilers, the company carried on careful experiments and developed an atomizing nozzle which operates equally well with diesel oil or higher grades of fuel, less atomizing pressure being required as the grade of fuel is improved. When diesel fuel is forced through the nozzle at pressures of 1000 to 1500 pounds per square inch, the oil burns with a clear flame. Since no preheating or vaporizing is necessary, the flame can be lighted as quickly as the fuel supply valve can be operated. Unlike the vaporizing burners, the system does not require concrete troughs or anchorages, thus simplifying installation problems. The nozzles, small steel tubes, are buried almost flush with the ground and require only simple bar guards for protection. By using combinations of various types of nozzles a wide range of thermal capacities can be obtained.

Arcata Airfield, about 350 miles north of San Francisco on the Pacific Coast, was chosen for experimental purposes because of severe fog conditions, weather data having shown the section to be one of the worst fog-bound places in the world, with fog rolling in and out several times during the day with very little notice. The installation at Arcata consists of a pumping unit with capacity of 840 gallons per minute of diesel oil at 1500 pounds per square inch pressure. This pump supplies fuel to a row of burner nozzles so arranged that fuels can be burned at various capacities to develop up to nine million British thermal units per hour per yard of runway length.

A Positive Waterproofer

Out of America's wartime laboratories emerges another miracle product. This one is of special interest to the marine field. It is Soldine V-110, a positive waterproofer, weatherproofer and preserver of fabrics. It's the answer to the mariner's desire for a formula that will keep precious water in fabric containers—that will make protective fabrics absolutely waterproof. It is the "This far and no farther!" for every wave that previously swept past a weather cloth.

From canvas canoe to ocean liner, marine uses for Soldine V-110 are universal. Its potentialities are limited only by number of articles that the water-sportsman, yachtsman, or ocean-going fleet owner has to waterproof.

Water—and its offspring, moisture, rot, mildew—has now been met and conquered by the use of V-110 on hatch covers, lifeboat covers, storage tarps, canopy and side curtains, canvas life preservers, weather cloths, sailboats and storage tops. Soldine Corporation of Evanston, Illinois, working with chemists from Northwestern University, is responsible for the development of this versatile formula.

Supplying water to our troops for drinking, cooking and other battle needs, often presents great difficulties. Out in the South Pacific it was necessary to obtain water from muddy streams and rivers, even from the salty ocean, or trek it through dense jungles, over tortuous mountain trails. Then the water had to be distilled and stored. An unforeseen difficulty arose in the matter of storing the water. Canvas tanks of 3000 gallons capacity were originally designed for this purpose but the supposedly waterproof canvas of these tanks could not withstand the water pressure of 5 psi, plus the punishment of continual folding, rolling and packing. The canvas would leak, crack and peel. Numerous ways were tried to overcome the obstacle, but to no avail, until Soldine V-110, barely out of the laboratory, was applied to the tanks and did the trick. This was also found applicable to the impregnation and waterproofing of airplane cloth. All branches of the service found many and equally impressive uses for this new material.

As wartime assignments decrease V-110 will be released, in gradually increasing quantities, to the civilian market.

Thomas Coakley elected president of the Board of State Harbor Commissioners.

Coakley Head of Harbor Commission

Thomas Coakley was elected president of the Board of State Harbor Commissioners at a meeting of the board in San Francisco. He succeeds G. W. Mailliard, Jr., who resigned the post in order to serve as Finance Committee chairman in Governor Earl Warren's campaign for re-election.

Coakley is a member of the San Francisco law firm of Littler, Coakley and Lauritzen and has been a member of the Harbor Commission since May, 1943. Previously, he served as a deputy attorney-general of California under Earl Warren.

Other members of the board are W. G. Welt and N. Loyall McLaren. McLaren was recently appointed to fill the vacancy created by the resignation of Mailliard.

Vice President Appointment

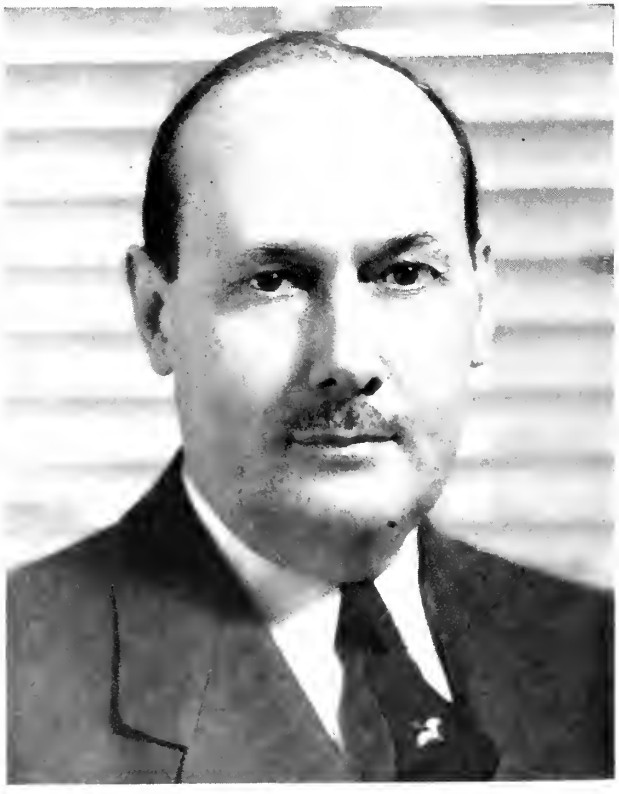
Nordberg Manufacturing Company, through its President, Robert E. Friend, on February 25th announced the election of F. H. Kilberry to the position of executive vice president and director, to fill the vacancy created by the resignation of C. E. Stryker, who has been associated with the company since 1940 in the capacity of vice president and assistant to the president.

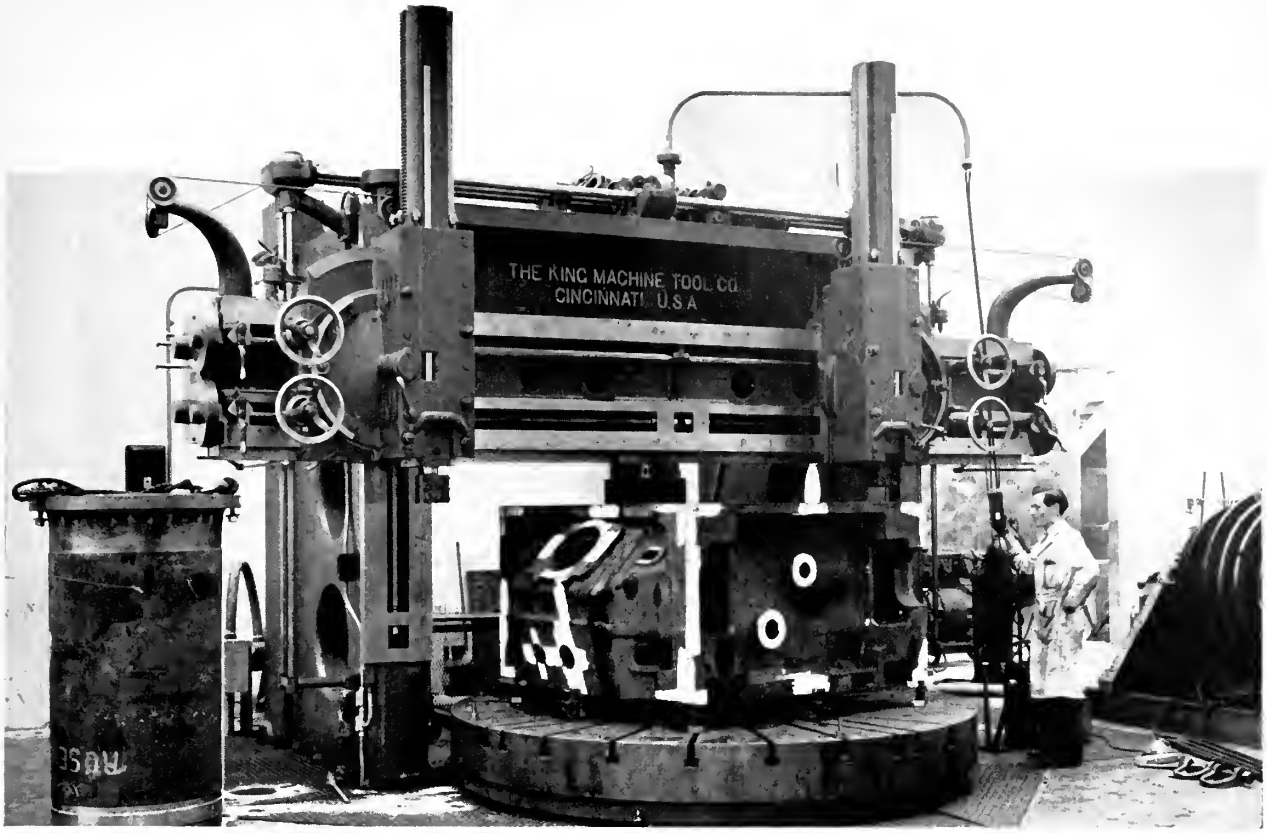
Mr. Stryker has been elected president of the Adel Precision Products Corp., of Burbank, California, and will assume his new position on March 1, 1946.

F. H. Kilberry has been identified with capital goods industries since 1920. In 1928 he became associated with Atlas Imperial Diesel Engine Company of Oakland, California. He was appointed assistant to the president and a director of that company in June, 1929, and in 1930 was appointed general manager. In 1932 he was elected vice president and general manager, and served in that capacity until his election to the presidency in 1938.

Under his management Atlas Imperial Diesel Engine Company developed from a West Coast operation to a position of international prominence in the smaller heavy duty Diesel engine field. Domestic activities were expanded to include an eastern plant at Matoon, Illinois, and four wholly owned sales and service subsidiaries located in New York, Seattle, Washington, Houston and Vancouver, British Columbia.

F. H. Kilberry, executive vice president of Nordberg Manufacturing Company.





King vertical boring mill with a 10-foot table working on a 5-ton upper cylinder head for the MS John Ericcson. The machine has two tool arms, which can be raised 76 inches above the table. It bores two interior, or an interior and an exterior surface simultaneously. . . . a scene in one of the shops of General Engineering and Dry Dock Corporation in San Francisco.

Architects rendition of the Flintkote Research Laboratory at Morristown, New Jersey. The architects on this plant are Lacy, Atherton, Wilson & Davis of Wilkes-Barre, Pa.

Flintkote's New Research Laboratory and Wind Tunnel

Construction of a new research laboratory at Morristown, New Jersey, costing about $1,000,000 for plant and equipment is announced by I. J. Harvey, Jr., president of the Flintkote Company, New York. This is part of an accelerated program of product research and development and plant expansion representing a contemplated outlay of approximately $10,000,000.

Mr. Harvey also announced that a wind tunnel, believed to be the first installation of its kind by any manufacturer of roofing and siding materials, will be installed to test full-scale sections under wind velocities up to 70 miles per hour. There materials will undergo accelerated weathering tests and temperature trials, in addition to standard tests used in the industry for many years. In connection with this research an outdoor exposure farm covering 20,000 square feet in area will provide check testing under normal conditions. A companion exposure farm will be located at New Orleans to gage different climatic conditions found there. It is anticipated that sections up to full-scale home and farm structures will be tested at these exposure farms.

USMS-Radar and Electronics School

In keeping with its declared policy of maintaining an adequate supply of trained and efficient merchant marine personnel in all categories, and in recognition of the rapid adoption of radar and other electronic aids to navigation by the shipping industry, the U. S. Maritime Service has established a Radar and Electronics School at Sheepshead Bay, New York, it was announced by Captain H. J. Tiedemann, USMS, Pacific District Operations Officer at San Francisco.

Radio operators holding second grade radiotelegraph licenses or higher who have served a minimum of two years as radio operators in the Merchant Marine subsequent to December 7, 1941, and who are willing to remain at sea for at least one year upon completion of training, will be eligible for an 8-week course in maintenance and servicing of radar and such additional electronic adjuncts to safe and efficient vessel operation.

USMS Officer Assigned to Post

Following a career at sea and on the West Coast, Commander Stuart L. Patton, USMS, is busy preparing for his new duties as officer in charge, Training Aids Unit, U. S. Maritime Service Training Station, New York. He plans to be at his new task April 1, 1946.

It was on December 11, 1941, that Patton enlisted in the Coast Guard. He served in the public relations unit of the Coast Guard for about nine months.

On September 1, 1942, Patton became officer in charge of the United States Maritime Service Center. In September 1, 1944, then a lieutenant commander, he assumed the duties of executive officer for the Pacific District operations office of the USMS. This position he has held until his new assignment in New York.

Harold Dabbs, S. F. Junior Chamber of Commerce; Carroll Reeves, Propeller Club; O. C. Hansen, Foreign Trade Assn. of the S. F. C. of C.; G. E. Hay, General Steamship Corp., Ltd.; Thomas A. Short, Mariners Club; Roy C. Ward, Commercial Club; Vice Chairman W. E. Martin, of Westinghouse Electric Corp.; Joseph J. Geary, president of Propeller Club; George V. Cooley, Pacific - American S. S. Assn., and Gene Haffman, advisory committee chairman.

S. F. Preparatory Meeting for the Observance of National Maritime Day

National Maritime Day on May 22 commemorates the sailing of the S. S. Savannah, first steamship to cross the Atlantic Ocean in 1819 from Savannah, Ga., to Liverpool, England. In thirteen years since the presidential proclamation by the late President Franklin D. Roosevelt, National Maritime Day has grown until today it ranks equally with Army Day and Navy Day because of the importance of a substantial merchant marine to the peacetime prosperity and wartime safety of the United States. The observance locally not only will tie-in with the national program but will stress the great amount of good which accrues to the San Francisco Bay Area from the water-borne traffic through the Golden Gate.

General chairman Hugh Gallagher, vice president in charge of operations for Matson Navigation Company heads a committee of leaders in the shipping business planning observance and has appointed key men to see that the program now being adopted for this year will be carried out.

The general committee comprises: vice chairman, W. E. "Eddie" Martin, Westinghouse Electric Corp., publicity director, Frank C. DiMarco; George V. Cooley, Pacific-American Steamship Assn.; Harold Dobbs, San Francisco Junior Chamber of Commerce; E. H. Harms, Shipowners' Association of the Pacific Coast; Arnold Larsen, United Seaman's Service; D. N. Lillevand, Waterfront Employers' Association; H. H. Pierson, San Francisco Marine Exchange; Carroll Reeves, Propeller Club; Thomas A. Short, Mariner's Club and Roy C. Ward, Commercial Club.

Hugh Gallagher, vice president of Matson Navigation Company, chairman of the San Francisco Propeller Club Committee for the Observance of National Maritime Day, May 22.

Eugene F. Hoffman, American President Lines, is chairman of the Advisory Committee, which is to be entrusted with the important task of putting the program into action. Various shipping interests of San Francisco are combining to make this year's observance outstanding.

McCormick Changes Name to Pope & Talbot Lines

Pope & Talbot-McCormick Steamship Division henceforth will be known as Pope & Talbot Lines. The change was announced March 26 by Charles L. Wheeler, executive vice president of the parent company Pope & Talbot, Inc.

The new name has been under consideration for some time and was voted recently by the board of directors in San Francisco, Wheeler said. The company's ship markings will be designated with P T in red letters on a white circle within a blue star on the funnel and a house flag of the same insignia to identify Pope & Talbot Lines.

The McCormick Steamship Company as a firm identity is an old one in shipping annals, and was acquired by Pope & Talbot, Inc., in 1935. Since that time it has been legally known as the Pope & Talbot-McCormick Steamship Division and the name change to Pope & Talbot Lines is made to correctly identify the steamship company and its parent organization.

Pope & Talbot, Inc., in four years will be 100 years old and is the oldest lumber and shipping concern on the West Coast. The company operates vessels in intercoastal and coastwise service and between Pacific Coast ports and Puerto Rico.

Vice Admiral Richard S. Edwards, USN, commandant of the Western Sea Frontier.

Western Sea Frontier Gets New Chief

The command of the Western Sea Frontier, the highest ranking naval position on the West Coast, changed hands when Admiral Richard S. Edwards replaced Admiral Royal E. Ingersoll in ceremonies at the Federal Office Building in San Francisco.

Now headed by Admiral Edwards and his staff, the Western Sea Frontier embraces a huge sea area off the U. S. West Coast, extending northward almost to Alaska, westward almost to Hawaii, and southward almost to South America.

Mare Island Moves To Vallejo Address

According to Washington newspaper reports received in San Francisco, the address of the Mare Island Naval Shipyard has been changed from Mare Island, California to Vallejo, California.

USMC Member Sworn In

Richard Parkhurst of Boston, Mass., was sworn in on February 20, as a member of the United States Maritime Commission.

Present at the ceremony were Acting Chairman **Edward Macauley**, Commissioner **Raymond S. McKeough** and Commissioner **John M. Carmody**.

The Upson-Walton Company, Cleveland, manufactures wire rope, tackle blocks, boat fittings, accessories and brattice cloth in the modern plant. Inset shows original quarters of company in 1871.

Upson-Walton Company in 75th Year Sees Greatest Period Ahead

The Upson-Walton Company, of Cleveland, celebrated its 75th Anniversary February 1 by formulating its plans for the greatest period of achievement in this wire rope and ship chandlery company's history.

They are manufacturers of numerous products, including wire rope, tackle blocks, boat fittings, accessories and brattice cloth.

Joseph E. Upson and John W. Walton started out 75 years ago by forming a ship chandlery partnership for the purpose of serving the Great Lakes marine trade and for the rigging and fitting out of any vessels at the shipyards on the Great Lakes.

Today, the company maintains two plants at 12500 Elmwood Avenue; a forging plant in which its tackle blocks and fitting are made, and a wire rope plant which was completed in 1942, which is an outgrowth of one formerly operated in New Jersey at the beginning of World War I when it became impractical to import wire rope from Great Britain. Removal of the wire rope plant to the midwestern section of the country, where it is more accessible to industry, has also aided in the company's recent growth. The original headquarters of the company along Cleveland's river front still stands but is now used only as auxiliary space.

PMR's camera caught this Ets-Hokin Galvin crew in action, installing C-O-Two Fire Equipment unit on the tuna vessel White Star at San Francisco during March. The White Star will be featured in the May Pacific Marine Review.

Appointed Distributors of "Wilco" Products

Martin and Turner, marine supply house of Wilmington, California, covering the entire Los Angeles harbor area have recently been appointed distributors for Wilber & Son, manufacturers of "Wilco" life preservers as well as the Diamond Rubber Company, for the sale of rubber hose and mechanical rubber goods.

George W. Gammon, Jr., well known naval architect is now associated with this concern in a marine technical advisory capacity.

Martin and Turner are increasing their activities and lines in the marine supply field and have recently moved their San Francisco office into larger quarters there.

Harold von Rolf who has been associated with this firm for the past four years was recently elected a vice president, and **Eric L. Pedley,** who is in charge of the San Francisco office, was elected a vice president as well.

Shipping Executive Entering Terminal Business

W. J. Bush, well-known West Coast shipping executive, has resigned as vice president and operating manager of the American President Lines to enter the terminal business, it was recently announced by E. Russell Lutz, executive vice president, APL.

William J. Bush, former Vice President, Operations, APL

Mr. Bush and associates, including some Portland interests, have purchased control in the Oregon Terminals (Oceanic Docks) in Portland. With the resumption of normal peacetime sailing schedules, the docks will be re-opened as a public terminal to handle all types of cargo, including refrigerated cargo.

A native of San Francisco, Mr. Bush began his shipping career as an office boy for the old Pacific Steamship Company, eventually becoming secretary, and later became secretary to R. Stanley Dollar. He rose rapidly in the ranks of the old Dollar Lines and in 1936 was elected vice president in charge of operations.

In 1938 when the Dollar Lines was taken over and reorganized by the U. S. Maritime Commission and renamed American President Lines, Mr. Bush continued in the position as vice president and operating manager.

Cunard White Star Manager Visits S. F.

Europe is not ready to receive the pleasure traveller. This message was voiced in San Francisco by E. Seymour-Bell, assistant general manager of Cunard White Star, Ltd., recently on his visit to the Pacific Coast in formulating plans for post-war travel.

The Cunard White Star lines, which operate the S.S. Queen Mary, the S.S. Queen Elizabeth and other large ships, are receiving countless numbers of inquiries from residents of the Pacific Coast States on the possibilities of trans-Atlantic travel. But European countries are recovering slowly from the effects of World War II. Housing and food conditions there are sadly inadequate so that the traveler is going to find difficulty for some time in visiting Europe.

Mr. Seymour-Bell disclosed that several hundred thousand dollars worth of equipment for the Queen Elizabeth was stored in San Francisco up to a fortnight ago and has just been shipped East to complete the reconditioning of the huge vessel.

"A Shot in the Arm"

World-famed as a shipbuilder, Joseph A. Moore, Sr., of the Moore Dry Dock Company, comes up with many a good story, like this one:

As a warehouse guard was making his rounds one night he saw a head rising above a pile of lumber. In proper shipyard language he demanded an explanation and failing to get it, he shot the figure in the arm. In the cold light of dawn, the figure turned out to be the one shown in the accompanying picture, one Timothy A. Folger, whose biography appears in the Moore archives as follows:

"Timothy A. Folger, born 1736—died 1803, whose likeness is reproduced in the sailing ship figurehead which now adorns the south garden of the Moore Dry Dock Company, was the son of Joseph Folger, a descendant of the Folger who came from Ireland and settled in Rhode Island in 1642. Timothy was the great, great grandfather of Roy S. and William Folger of San Francisco. Timothy was a man of extraordinary natural talent and though, like many of his descendants, he only attended the most elementary schools, he became a distinguished lawyer and scientist. His literary attainments also were unusually brilliant and he was the father of certain remarkable inventions. He served his time aboard a sailing ship and this experience combined with his scientific knowledge, resulted in the development of some important marine inventions. He was a man of deep religious convictions but under the urge of financial desire he abandoned his churchly affiliations to become an influential member of an insurance group. And through this association he accumulated great wealth and thus established the foundation of the present Folger fortune."

The Moore's have established the Folger figurehead in the garden by their office door, and the spot is a favorite gathering place for distinguished visitors.

Distinguished Gentlemen at Moore Dry Dock Company Meet the Honorable Timothy A. Folger

Left to right, seated: W. H. Gerhauser, pres. American Shipbuilding Co.; Rear Admiral L. O. Colbert, director of Geodetic & Coast Survey, Washington, D. C.; Jack Belanger, General Electric Co., New York; Joseph A. Moore, Sr.; the late Vice Admiral Howard L. Vickery; Roy S. Folger, insurance executive; Carl W. Flesher, former regional director, U.S.M.C.; Munroe Lanier, pres., Ingalls Shipbldg. Corp.; Jos. A. Moore, Jr., pres. Moore Dry Dock Co.; and N. Levy, vice pres. and secty. of Moore's.
Standing: Charles Bryan, vice pres., Federal Shipbldg. Co.; Lt. Col. Horace G. Foster; G. H. Johnson, technical asst. to late Admiral Vickery; Timothy A. Folger, guest of honor; H. H. Haight, asst. vice pres. Crocker First National Bank; Harry W. Fowke, supt. hull construction, Moore Dry Dock Co.; Lt. Wm. A. Weber, asst. to the late Admiral, and James R. Moore.

Clinton E. Stryker, president and general manager of Adel Precision Products Corp.

General Manager of Adel Precision

Clinton E. Stryker of Milwaukee, has been elected president and general manager of Adel Precision Products Corp., of Burbank, California, according to an announcement by Henry S. Wright, chairman of the Adel board of directors.

Mr. Stryker was formerly vice president and assistant to the president of the Nordberg Manufacturing Company of Milwaukee, manufacturers of diesel engines and heavy machinery. Before that he was a partner with McKinsey, Kearney & Company, management consultants of Chicago. He has a broad experience in scientific management, engineering and manufacturing. He assumed his new duties with Adel on March 4.

Adel Precision Products Corp. is a major manufacturer of hydraulic equipment for aircraft.

Standard Oil Consolidated

In a move designed to give greater emphasis to mechanical development and engineering research, Standard Oil Development Company, central technical organization of Standard Oil Company (New Jersey), announced consolidation of its two engineering departments.

The consolidation brings into one organization more than 400 scientists and other employees of the General Engineering Department and the Process Engineering Department which have operated independently for nearly 10 years. The new organization, named the Esso Engineering Department, is directed by E. W. Luster, chief engineer, who reports to Dr. N. E. Loomis, vice president in charge of engineering.

Under the new setup, E. H. Barlow, former chief engineer, becomes consulting engineer of the development company, handling many of the contacts with company executives on engineering matters of general interest. Assistants to Mr. Luster are P. J. Byrne of the Process Engineering Department; C. E. Paules of the General Engineering Department, and N. F. Myers, former associate manager of the process division.

C. T. Harding is named chief process engineer, C. F. Hesselbach, chief mechanical engineer, and A. J. Ely, chief construction engineer. As part of the reorganization, a group of project engineers including G. W. Bauer, E. H. Clendenin, P. J. Harrington, C. A. Hillman, E. H. Kares and J. R. Schonberg, will serve as coordinators on major projects.

Pope & Talbot and Quaker Lines Coordinate Services

To provide a more frequent and complete service between Atlantic and Pacific Coast Ports, Pope & Talbot, Inc. (McCormick Steamship Division) and the Pacific-Atlantic Steamship Company (Quaker Line) General and Berth Agents for the War Shipping Administration announced recently the completion of plans for a new intercoastal steamship schedule immediately. The new schedule embraces a fleet of modern ships operating on a 10-day frequency between Atlantic Coast ports and Pacific Coast ports and is the result of the cooperation of these two companies with the W.S.A.

This new service will be of immeasurable benefit to shippers and consignees who may take advantage of the dual facilities and offices of the two carriers for sailings, ports of call and other information to expedite their shipments. Under this new coordinated schedule the first sailing westbound will be the S. S. Nampa Victory from Baltimore, March 16; Philadelphia, March 20; and Norfolk, March 22, followed by the S. S. Water Witch from Baltimore, March 26; Philadelphia, March 30; and Norfolk, April 1. Eastbound, their first sailings will be the S. S. Middlesex Victory from Puget Sound, April 1; Portland, April 5; San Francisco Bay, April 8; Los Angeles, April 10; followed by the S. S. Ocala Victory, Puget Sound, April 10; Portland, April 15; San Francisco Bay, April 18; Los Angeles, April 20.

Both the Quaker Line and Pope & Talbot, Inc. (McCormick Steamship Division) maintain terminals at the important coastal cities of both Atlantic and Pacific ports and are well equipped with modern dockside facilities for the rapid handling and dispatch of all cargo.

Foster Wheeler Gets Record Boiler Order

One of the largest stationary boiler orders ever placed in this country and valued at nearly $5,000,000 was received by Foster Wheeler Corporation.

The order, covering four steam generators, calls for the largest boilers ever designed for direct firing with pulverized anthracite. Each of the units will be capable of producing 400,000 pounds of steam per hour at 1350 pounds per square inch and at 955 degree Farenheit temperature.

The steam generators were ordered by the Pennsylvania Power & Light Company for its new 150,000 kilowatt steam-electric station scheduled to be completed at Sunbury, Pa., in the spring of 1948.

Ebasco Services, Inc., is handling the engineering and construction of the new plant.

Partners of Hunt, Mirk & Company. At left, Lee W. Delhi, president of California Metal Trades Assn., and Thomas J. Benney, senior member of the firm.

Lee Delhi Joins Hunt, Mirk & Co.

Lee W. Delhi, nationally known welding engineer and shipbuilder, has resigned as vice president in charge of operations at Western Pipe & Steel Company to become a member of the pioneer engineering and contracting firm of Hunt, Mirk and Company, San Francisco.

Announcement of Mr. Delhi's affiliation with Hunt, Mirk and Company was made recently by Thomas J. Benney, senior member of the firm, who said that Mr. Delhi's entry into the company will strengthen its financial position as well as expedite its post-war expansion program.

Hunt, Mirk and Company was founded in 1903, and has been active continuously in the engineering and construction of steam power plants, marine engineering, and all phases of steam distribution systems, electrical construction and hydro-electric installations.

During the war, Hunt Mirk's activities were confined largely to the development of engine room design work for the U. S. Maritime Commission and other governmental agencies. The company is now preparing to resume its pre-war activities on a more comprehensive basis. This will include design and construction of steam and power plants for lumber, food, cement, chemical and oil industries.

Mr. Delhi is president of the California Metal Trades Association. He is also national director of the American Welding Society and previously served two terms as Pacific Coast regional vice president of the organization.

With the purchase of Western Pipe & Steel by Consolidated Steel Corporation of Los Angeles, Mr. Delhi concluded 22 years service with the company. Under his direction the company designed and built more than 48 special all-welded C3-type vessels for the U. S. Maritime Commission, practically all of which were converted into specialized vessels for Army and Navy use.

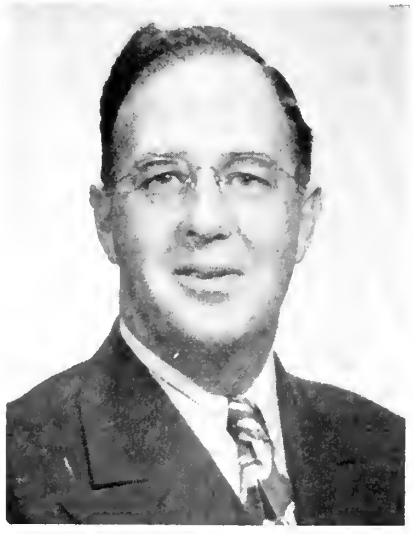
Mr. Delhi also had charge of the fabrication of many thousands of tons of steel for other firms, as well as a comprehensive program of ship repair work for the Navy and War Shipping Administration.

Consolidation of Matson's Maintenance Division With United

The facilities of the maintenance division of Matson Navigation Company's construction and repair department and United Engineering Company Ltd., have been consolidated under the name of United Engineering Company, a wholly owned subsidiary of Matson devoted to ship repair and maintenance, it was announced on March 25 by W. P. Roth, chairman of the board of Matson and R. E. Christy, former president of United Engineering Company Ltd.

United Engineering Company will have two plants, one at 500 Beale Street, San Francisco, and the other at the former United Engineering Company Ltd's ship repair yard on the Alameda Estuary. United Engineering Company Ltd's. Steuart Street and Folsom Street plants will be devoted to other use. United Engineering Company's San Francisco and Alameda plants include modern shops, warehouses and office facilities, and the Alameda plant operates two dry docks of 10,000 and 14,000 ton capacity as well as more than one mile of berthing space for vessels undergoing repair.

The maintenance division of Matson's construction and repair department had its inception in the latter part of 1924 on the ground floor of a building adjacent to the Embarcadero on San Francisco's waterfront. Fourteen years later its shop locations were transferred and expanded in a newly constructed building at 500 Beale Street. With the declaration of the National Emergency and the corresponding increase in Army, Navy and merchant shipping required to fight a global war, Matson was asked by the Government to expand its ship repair facilities. During 1942 the Division grew until its plant covered two city blocks and embraced an outfitting dock at Pier 36 operated for the United States Navy, and a repair dock at Pier 60 assigned to the company by the War Shipping Administration.



J. Paul Thompson, president.
United Engineering Company.

The United Engineering Company Ltd was founded in 1917 in a small machine shop on Spear Street near San Francisco's waterfront. In 1920 the Company purchased the property of the Risden Iron Works at Steuart and Folsom Streets which served as headquarters until the end of 1945. In 1940 property was acquired in Alameda on the Oakland Estuary previously occupied by the repair shops of the Southern Pacific Railroad, and a combination ship construction and repair yard was established which played an important role in handling the tremendous volume of such work being performed in the Bay Area during the war principally by constructing and delivering to the United States Navy twenty-one sixteen hundred ton ocean-going tugs.

Officers of the United Engineering Company include Mr. Roth and Mr. Christy as chairman and vice chairman of the Board, respectively, J. P. Thompson, president, George Sutherland, vice president and works manager, R. P. Hasenauer, treasurer.

Sailings From P. C. Ports to Puerto Rico

Allocation of merchant ship tonnage to move cargo from Pacific Coast ports direct to Puerto Rico has been approved on a test basis, the War Shipping Administration recently announced.

Pope & Talbot, Inc., has been designated as berth agent to handle the direct shipment of cargo.

Prior to the war, intercoastal cargoes destined for Puerto Rico were carried on regular East-bound voyages by American-Hawaiian Steamship Company and Pope & Talbot, Inc. Since resumption of intercoastal operation, many ships have been operating East-bound at full capacity and the handling of Puerto Rico cargo on these voyages would conflict with this through traffic.

In approving the trial allocation of a monthly sailing to Puerto Rico, the WSA approved allocation of other tonnage for future additional direct sailings to Pope & Talbot, Inc., and American-Hawaiian Steamship Co., if the cargo conditions justify it.

New No. California Marine Paint Firm

Manning-Mitchell, Inc., a new organization of marine paint specialists, announces a complete line of marine and industrial paints. Featured among the company's products are antifouling and anticorrosive paints, claimed to be extremely effective and long-lasting, and solutions for the treatment of steel to double the effective life of ordinary paint coatings.

Members of this firm's management are all veterans of the Navy's special protective coating department. Their intimate contact with and important contributions to its development of superior types of antifouling and anticorrosive bottom paints have gained for them reputations as authorities in the field.

Bernard M. Wolfe, president, held supervisory positions in the construction and repair division at Mare Island Navy Yard, in charge of the coordination program between research, manufacture and application of the antifouling paints and protective coatings. He was responsible for organizing the preservation program in the Navy Yard for the inactive and reserve fleets. A graduate of the United States Naval Academy and the Post Graduate School, U. S. Naval Academy, he is a member of the Society of Naval Architects and Marine Engineers.

F. J. Dannenfelser, vice president, is a graduate mechanical engineer and naval architect (University of Michigan and Post Graduate School, U. S. Naval Academy). During his more than four years' service in the Navy, he equipped and instructed personnel and made official reports on sandblasting and application of the new plastic underwater paint at all shipyards in the continental United States east of the Mississippi River and in the West Indies. Prior to entering the service, Mr. Dannenfelser was associated with the DeVilbiss Company as a special paint equipment engineer.

Robert M. Mueller, secretary-treasurer, is a graduate architect and naval architect (Cornell University and Post Graduate School, U. S. Naval Academy). His assignments in the Navy were similar to Mr. Dannenfelser's. In addition, Mr. Mueller also proposed and helped to engineer the installation of a new plant for application of plastic paint at Kaiser Shipyard No. 3, Richmond, California. Before release to inactive status, he was stationed at Kaiser Yard No. 3 as Naval inspector.

Main offices of Manning-Mitchell, Inc., are located in San Francisco. Expansion developments are now under way for distribution of its products throughout California, the Pacific Northwest and the Gulf Coast.

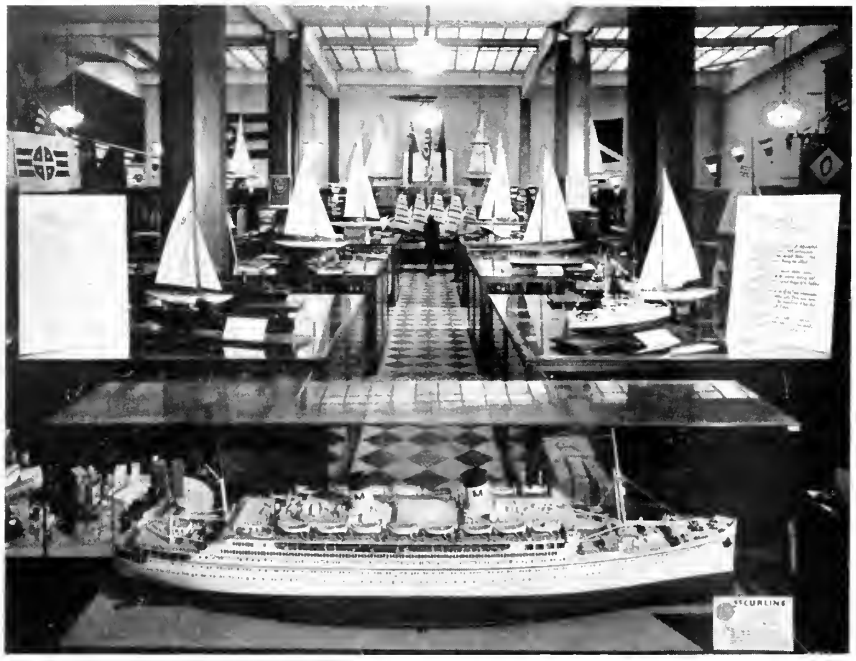
BON VOYAGE: Norris Nash, public relations director of the Richmond shipyards for the past three and a half years, left recently for Willow Run, Michigan, where he is now associated with the administrative management of Kaiser-Frazer Motor Company.



The Ship Model display at Atkins' during March of this year.

SHIP MODEL CONTEST SPONSORED BY ATKINS

The second annual exhibition of ship models was recently held in Robert S. Atkins Company men's clothing store in San Francisco, for all those who love the sea and the ships that sail the seven seas. The Marine Exchange, the Museum of Science and Industry, and members and friends of both organizations have loaned models of ships, yachts and power boats for the splendid display. Models of every class,—old clippers, schooners, warships and other sailing and steam ship models, as well as the latest C-4's and others of the U. S. Maritime Commission built vessels, and the very recent Navy types were on display.

Hundreds of people have visited the store and inspected the craftsmanship and design of the distinguished five masted square-rigged German ship Preussen, which dominates the assortment of fine models. This collection is one of the best that has ever been assembled in San Francisco. It seems to this writer that such a fine collection should have a permanent home in a marine setting, like the former Aquatic Park museum which housed part of it before the war.

Fanciers of ships in bottles can see in this exhibit some remarkable work by Charles Van Remoortel, who specializes in building accurate small models in bottles with long and slender necks. Then there is the work of the Preston-Dahl firm, professional San Francisco model builders, to be seen in the model of a C-4 and the famed Gjoa, Roald Amundsen's Arctic exploration ship. The Boucher Model Works in New York is represented by the Matson Navigation Company's Lurline model, and the model of the Preussen made by Eric Swanson, who spent about four years in its construction. It is built on a scale of ¼ inch to the foot, after official plans.

SHORESIDE PERSONALITIES

Back With U. S. Lines

John F. Brennan, after serving as a lieutenant colonel in the Army, has resumed his post as head of the passenger department of the United States Lines, according to an announcement by John M. Franklin, president.

Part of Brennan's war service included two months duty in the office of the Chief of Transportation in Washington. Transferred to the New York Port of Embarkation at Brooklyn he was responsible for planning and controlling the distribution of all supplies for the U. S. Army Forces in the European and Mediterranean theatres of operation. San Francisco steamship and transportation men became well acquainted with him after V-E Day when he was assigned to the San Francisco Port of Embarkation in charge of similar supply operations for the Pacific theatre. Before the war, he served with the U. S. Lines passenger organization and was promoted to passenger traffic manager in 1936.

Another recent appointment by John M. Franklin, president of U. S. Lines, is that of Raymond M. Hicks, an executive of the company who has been made executive vice president.

William H. Schwartz, executive engineer of Alvin R. Campbell Co.

Schwartz Joins Cargo Handling Co.

William H. Schwartz is now executive engineer for the Alvin R. Campbell Company of San Francisco, designers and manufacturers of cargo handling equipment.

For the past five years Schwartz was assistant chief hull draftsman, in charge of ship repair and conversion with the Shipbuilding Division, Bethlehem Steel Company in San Francisco.

He graduated from the University of California as a mining engineer in 1936 and thereafter proceeded to Bolivia where he served for three and a half years as chief engineer and assistant mine superintendent with the Compania Minera Unificada del Cerro Rica de Potosi, returning to the U. S. A. just prior to the outbreak of war.

Battery-Powered Truck

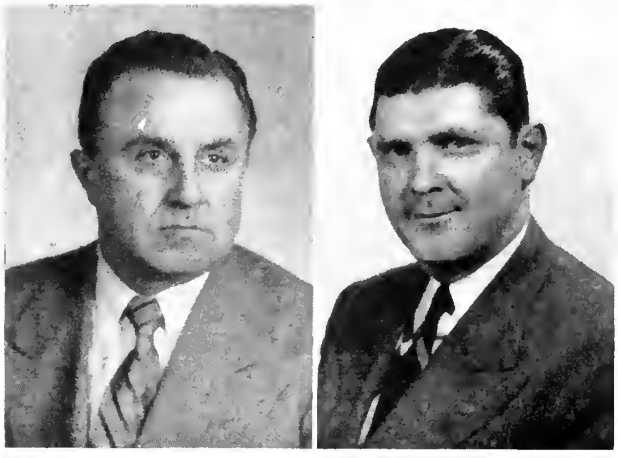
Convinced that industry's best post-war chance to cut manufacturing and distribution costs of consumer products, thereby creating more jobs and widening markets, lies in mechanizing its handling of materials, the Electric Industrial Truck Association has embarked on a broad program for 1946 to promote interest in the economics of the idea and to prove that the battery-powered truck belongs in that picture on the basis of performance.

Gordon J. Berry, Cleveland, president of the Association says that the program will dig down to fundamentals in establishing the proved advantages of the battery-powered truck in mechanized systems of material movement and storage.

Resigns WSA

H. Chase Stone, assistant deputy administrator in charge of recruitment and manning, War Shipping Administration, familiar to many in shipping circles on the West Coast, resigned his post effective March 1, it was announced by Granville Conway, acting administrator of WSA. Howard Hyde who was assistant director of this department will succeed Mr. Stone.

Another Shipping man connected with the WSA to leave his post is Felix Isherwood, who served as assistant to John E. Cushing, until the latter's return to the presidency of American-Hawaiian Steamship Company. Mr. Isherwood is joining the shipping company in an executive post under Mr. Cushing. He has seen service in Yokohama as agent for the States Steamship Company and also in Portland as agent for the Coastwise and United States Lines.



New vice presidents with Earle M. Jorgensen & Co. At left, Ralph K. Beall, vice pres. and director, and Paul C. Childs, vice pres. and district manager.

STEEL DISTRIBUTORS APPOINT VICE PRESIDENT

Ralph K. Beall has been appointed vice president and director of Earle M. Jorgensen Co., steel distributors. He retains his position as manager of sales of the Los Angeles office.

Paul C. Childs also has been appointed a vice president as well as district manager of the Oakland office.

Mr. Beall became associated with the Jorgensen Company in 1925 and Mr. Childs in 1933. The announcement of these promotions was made by Earle E. Jorgensen, president of the firm, as part of a reorganization made necessary by the company's expansion program. "Upon completion of building projects now under way," Mr. Jorgensen said, "our pre-war warehousing facilities will be more than doubled."

Returns to Jamison

The Jamison Cold Storage Co. of Hagerstown, Md., advises that J. V. Jamison 3rd has returned to take up his duties as president, after serving eighteen months on the heavy cruiser Wichita. His tour of duty was confined exclusively to the Pacific theatre, and he participated in the Second Battle of the Philippines, as well as supporting the landings and occupation of Okinawa.

J. V. Jamison, III, president.

Ed W. Whittemore of Atlas Marine Paint's Wilmington headquarters, and Richard E. Pierce, Atlas Marine Paint's San Francisco manager.

Atlas Paint & Varnish Company Names S. F. Manager

On a recent visit to San Francisco E. W. Whittemore of the Atlas Paint and Varnish Company of Los Angeles announced the opening of the Atlas Marine Paint Company of San Francisco, and the appointment of Richard E. Pierce as manager. The company will maintain offices and warehouse at 201 First Street, and will supply the entire line of Atlas marine paints and varnishes to the Northern California area.

Pierce, who is a graduate of the University of California, recently was released from the Army with five European and North African battle stars to his credit. He spent 11 months as a prisoner of war in a German prison camp.

Expansion of Atlas Line

Expansion of the new, improved line of Atlas Marine Paints, manufactured in Los Angeles, into the southern states has been announced.

The Galveston Ship Supply Company at Galveston and Houston, Texas, have taken over distribution of the specialized marine Atlas paints in their area through arrangements made by Ed Whittemore, sales manager of Atlas with J. C. Owen, manager and G. A. R. Dean, sales manger of the supply company.

New Gage Division

The Gotham Instrument Co. of New York announced the appointment of Jack Rudin to head their pressure gage department.

Mr. Rudin who was sales engineer for 24 years with the U. S. Gauge Co. and sales manager for the Champion Gauge Co., enjoys a wide acquaintance in the trade throughout this continent.

In addition to the manufacture of pressure gages, pressure recorders and controllers, the Gotham Instrument Co. is one of the largest independent manufacturers of industrial indicating, recording controlling and chemical thermometers in the U.S.A. with branch factories and offices at San Francisco, Chicago, and Canada.

HEROIC SHIP'S MASTER GIVEN DSM

With his wife by his side Captain Andrew W. Gavin, of New York (left), master of the Alcoa Pioneer, is presented with the engrossed citation accompanying award of Merchant Marine Distinguished Service Medal by Acting Chairman Edward Macauley, of the U. S. Maritime Commission.

(Continued from Page 375)

cargo winches, anchor windlasses, capstans and steering gears.

George E. Swett is a member of the Society of Naval Architects and Marine Engineers, Propeller Club, on the board of governors of the Mariners Club, and a director of the Citizens' Federal Savings and Loan Association of San Francisco, one of the oldest firms of its kind. He has two sons, Major James E. Swett, recently discharged from the U. S. Marine Corps after serving with great distinction, and Pfc. George E. Swett, Jr., just released from the U. S. Army. A daughter Margaret is employed by the firm.

A delightful and bountiful buffet lunch with accessories was served during the six-hour event.

Rosette to General Ship Supply Co.

Arthur B. Rosette, formerly sales manager of the Bay Cities Asbestos Company, has recently become manager of General Ship Supply Company. He is well known on the waterfront.

The General Ship Supply Company is one of the twin "General" units operated by Edward R. Berryman, who organized it in 1924 and followed with the General Ship Service Company in 1940. The latter company is engaged in chemical cleaning, boiler and tank cleaning, chipping, scaling and painting. Captain Vance D. Trout, who for many years was general superintendent of the United States Lines, is president and operating manager of this company.

During the war, both companies were operating on a 24-hour schedule. Due to the increasing business in the Slop Chest department and the need for larger warehousing facilities, an adjoining building in San Francisco was purchased and these increased facilities will be kept busy in this post-war period.

Earl Whitson will act as controller for both companies.

Left to right, Captain Trout, Arthur Rosette, and Mr. Berryman.

Admiral Joseph F. Farley (left) head of the U. S. Coast Guard, replaces Admiral Russell R. Waesche, retired, Commandant of the U.S.C.G. (at right).

Admiral Farley recently presented seven Coast Guard officers with Navy Commendation Ribbons.

COAST GUARD OFFICERS DECORATED FOR WARTIME SERVICE

Seven officers of the U. S. Coast Guard, well known to the maritime industry, have just received high decorations for their wartime service. This announcement was made by Coast Guard Headquarters, Washington, D. C.

Four received the Legion of Merit, and three were presented with the Navy Commendation Ribbon, on behalf of the Secretary of the Navy, James Forrestal. The presentation was made by the Coast Guard commandant, Admiral J. F. Farley.

Those awarded the Legion of Merit were Rear Admiral Harvey F. Johnson, USCG, engineer-in-chief; Rear Admiral Charles A. Park, USCG, chief operations officer; and Commodore E. M. Webster, USCG (retired), chief, Communication Division.

Officers receiving the Commendation Ribbon were Commodore F. P. Dillon, USCG, chief of the aids to navigation division; Capt. R. T. Merrill, USCGR, special assistant to the commandant; Capt. H. T. Jewell, USCG, Merchant Marine personnel division; and Capt. Rutherford B. Lank, USCG, assistant chief, Naval Engineering Division, Office of Engineering.

SPITFIRE TO PLY SOUTH AMERICAN LANES

Through the U. S. Maritime Commission, the 14,000 ton turbiner Spitfire, built at Consolidated Steel Company's yards at Wilmington, was delivered to the Grace Line on February 22. This vessel will operate in service between the ports of the West Coast of South America. This is the second vessel in a fleet of ten C-2 peace-built cargo vessels being constructed for the U. S. Maritime Commission Commission by Consolidated Steel's Los Angeles Shipbuilding division.

The Spitfire and her nine sisterships are the largest merchant craft ever built in the Los Angeles Harbor area, having an overall length of 459 feet, a 63 foot beam and displacing 14,000 tons.

Air-conditioned throughout, the Spitfire has a raked stem and cruiser stern. Its cargo features include deep tanks for dry or oil cargo, five cargo holds, three forward and two aft, special safety collision bulkheads forward and aft, several watertight bulkheads, and double masts which carry thirty ten and five ton cargo booms. The Spitfire is powered by turbines and has a cruising speed of approximately 19 knots.

Freakish February weather gives tropical voyager a taste of North Pole during construction in U. S. Steel's Federal Shipyard at Kearny, N. J.

Shoreside Personalities

Wade E. Miller of Higgins Pleasure Craft

HIGGINS NEW GENERAL MANAGER. Wade E. Miller, president of Higgins Pleasure Craft, 1811 S. Hope Street, distributors of Higgins products of Los Angeles and vicinity, has taken over the general management of the company following the resignation of Charles E. Dayton, February 19th.

Emerson Miller, brother of Wade, has joined the company in a sales capacity. The firm has a branch office at 1635 American Avenue in Long Beach and a showroom at 810 Coast Highway, Newport Beach.

LIEUT. FRANK C. DIMARCO, regional public relations officer for the training organization of WSA on the West Coast since last July was released from active duty March 1st to return to advertising and public relations activities in the Bay Area.

Originally enlisted in the U. S. Coast Guard shortly after Pearl Harbor, Lieutenant DiMarco was transferred to the Maritime Service to direct public relations and recruitment activities in Ohio, Michigan, and Kentucky. After more than two years of producing recruiting drives and city-wide Maritime Day observances, he was assigned to supervise public relations matters for the Training Organization on the West Coast; which position he held up until his release.

Lieutenant Frank C. DiMarco

Herman D. Nichols

Tubbs Cordage Executive Manila Bound

Herman D. Nichols, vice president of Tubbs Cordage Company, sailed March 1st for Manila, P. I., to assist in the rehabilitation of Philippine cordage properties. Working with other cordage people in the Islands, Mr. Nichols expressed the hope that increased quantities of Manila fiber will soon be on its way to this country to relieve the acute shortage of Manila rope that has existed since Pearl Harbor.

Among other cordage executives sailing with Mr. Nichols was C. A. Carter, vice president of the Manila Cordage Company.

Alaskan Distributor Visits L. A.

Elmer Fern, Alaska and Northern Canada distributor for Briskseal Refractory Co., and Xzit Sales Co., was a recent visitor to Los Angeles. During his stay in Los Angeles, Mr. Fern spent considerable time at the Brickseal and Xzit headquarters on South Hoover Street.

He handles distribution of Xzit fire scale and soot eradicator, Brickseal refractory coating and allied products in Alaskan ports, as well as principal towns of the interior and Northern Canada. Mr. Fern reports ample stocks of these products are maintained in principal ports of this northern territory.

Shipping Man C. of C. Head

Peter P. Mesquita was elected recently to the presidency of the Alameda Chamber of Commerce. PMR scribes first met "Pete" Mesquita in 1918 when he threw in his lot with George A. Armes, San Francisco builder of ships.

In 1934, "Pete" was appointed secretary-treasurer of the General Engineering and Dry Dock Company, a position which he has held ever since.

Peter P. Mesquita, recently elected president of Alameda Chamber of Commerce.

SURVEYORS AND EXECUTIVES OF AMERICAN BUREAU OF SHIPPING

ABS Surveyors on North America's West Coast

Los Angeles Harbor, Wilmington, California—Harry J. Summers, principal surveyor; Charles J. L. Schoefer, Charles J. Walker, Jr., Edwin W. Pike, David S. MacLagan, Harald N. Guldstrand, James E. Middlemas, John C. McKnight and Thomas G. Birdsey.

San Diego, California—K. M. Walker.

San Francisco, California—William B. Warren, principal surveyor for the Pacific Coast; Christopher D. Mues, William D. Schoning, Donald W. Day, Herbert A. Holm, Frank A. Jones, Thomas H. Purdom, Jr., Harold C. Amens, Jack Deckard and Ward F. Beckwith.

Portland, Oregon—Basil A. McLean, principal surveyor; Charles R. Hudson, John Ellison, James F. McCann, Jr., Joseph P. Long, Jr., Robert T. Ryan, Francis P. Miller, Clarence S. Montgomery, Robert Allen, Charles E. Stith, George B. King, Jr., Howard E. Hopkins, E. P. Turi, R. I. Randolph, B. O. Reese, E. L. Cox, Ray R. Faverty, Ludie H. Adamson, and Sidney S. Stewart.

Seattle, Washington—Sidney K. Smith, principal surveyor; John D. Wilson, Donald R. Head, Charles S. Rosenvold and Frank H. Gallagher.

ABS Surveyors on South America's West Coast

Callao, Peru—William H. Parsons.

Valparaiso, Chile—Herbert McLean.

ABS Surveyors in the Pacific

Malaya, Singapore—F. G. Ritchie.
Penang—H. T. Rigden.

China, Hong Kong—Anderson & Ashe in the Queen's Building.

Hawaii, Honolulu—John R. Black and Samuel C. Keller.

Philippine Islands, Manila—Ralph M. Johnson.

The East Indies, Batavia, Java—C. Van Steenwijk.
Sourabaya, Java—F. K. Kupper.

"Down Under" ABS Surveyors

Australia, Brisbane—James W. Herd.
Fremantle—R. J. Sinclair.
Melbourne—A. C. Meek.
Port Adelaide—A. J. R. Wood.
Sydney, New South Wales—David W. Gibson, acting surveyor.

New Zealand, Auckland—F. W. Blakey.
Dunedin—George W. Martin.
Wellington—George D. Lidgett, acting surveyor.

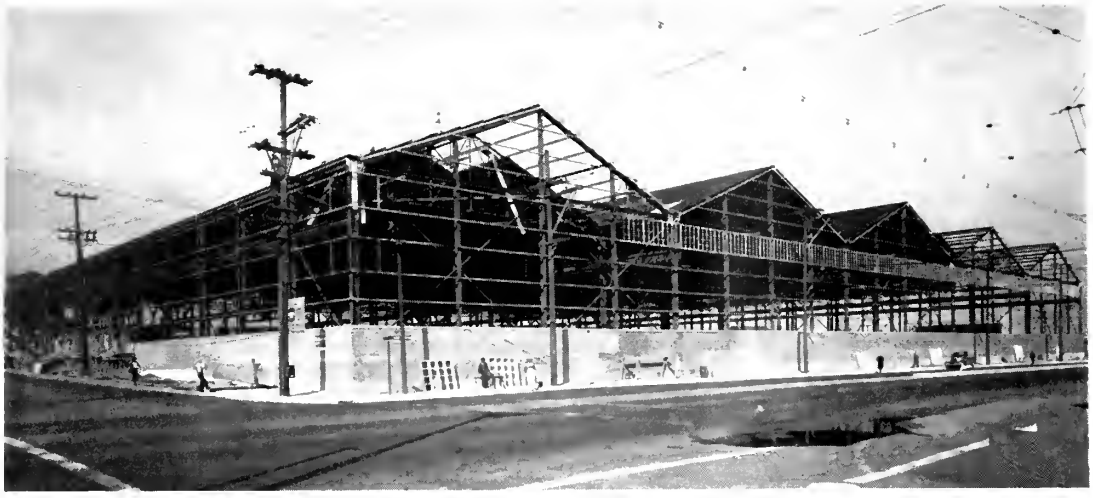
No changes have been made in the executive setup in the American Bureau of Shipping this year. J. Lewis Luckenbach was re-elected president and David Arnott, vice president and chief surveyor; Joseph W. Powell and William D. Winter, honorary vice presidents; Jerome B. Crowley, treasurer; John W. Cantillion, secretary and assistant treasurer, and Kenneth D. Hull assistant treasurer.

The ABS board of managers elected for a three-year term are: Donald C. Bowersock, Edward P. Farley, Homer L. Ferguson, John M. Griser, Basil Harris, Bushrod B. Howard, Daniel K. Ludwig, Joseph T. Lykes, Frederick R. Pratt, Henry R. Reed and H. Gerrish Smith. William H. Collins was elected for a one-year term.

The following men were elected to membership in the Bureau: Vice Admirals Emory S. Land and Howard L. Vickery (since deceased); William H. Collins, Bethlehem Steel Co.; F. R. Pratt, Socony Vacuum; W. L. Stewart, Jr., Union Oil Co.; Albert B. Kern, M. A. Hanna Co.; Miles F. York, Atlantic Mutual; Harold L. Gobeille, Cleveland-Cliffs Steamship Co.; W. C. Jones, Tomlinson Fleet, and A. T. Wood, Lake Carriers Association.

F-M Supervisor of Scale Service

E. L. Stine, who has been manager of the Scale department of the San Francisco branch of Fairbanks, Morse & Co., was appointed to the post of Supervisor of Scale Service with headquarters in Chicago.



San Francisco Mill Depot for Bethlehem Pacific Coast Steel Corporation nearing completion.

New Mill Depot for Bethlehem-Pacific

Without fanfare and while some strike bound Bay Area industries were marking time, one of the speediest steel erection jobs recorded in these parts was taking place at 3rd & Mariposa Streets. Here, a 4-acre plot of ground suddenly became a beehive of activity as a seasoned crew of steel erectors from the Bethlehem Pacific Coast Steel Corporation started placing the steel columns for a new mill depot for the Bethlehem-Pacific Company. The entire steel framework consisting of five 86 foot wide bays, each 375 feet in length and covering about four acres was erected in 17 working days.

The 1250 tons of structural steel used in putting up the steel framing for the building had been fabricated at the Alameda Works of Bethlehem Pacific's Steel Construction Division. During these preliminary operations, the foundations had been placed to support the structural steel framing members of the building.

Laying of the 170,000 square feet of steel roofing for the building is now nearing completion. Brick masonry work on the front wall of the building is finished. The mill depot is expected to be ready for occupancy by May 1st. It will be operated under the direction of W. C. Eshelman, general superintendent of Bethlehem Pacific's South San Francisco Steel Plant.

The methods employed for decades by steel fabricators in prefabricating and partly assembling the structural steel before actual erection are very similar to the mass production shipbuilding operations which were so widely publicized during the war. Many of these improved production methods were pioneered by Bethlehem's Fabricated Steel Construction Division and later adapted to shipbuilding practice in Bethlehem shipyards.

Bethlehem P. C. Steel Appointment

Bethlehem Pacific Coast Steel Corporation has just announced the appointment of **Edward G. English** as executive assistant to H. H. Fuller, president of the company. Mr. English was formerly manager of commercial research and supervisor of Pacific Coast mill scheduling. He started to work first for the Sheffield Steel Corporation in Kansas City, and later became assistant night superintendent of the sheet mill.

He joined the Pacific Coast Steel Company in 1925, serving in the engineering and sales departments at Seattle, Portland and Spokane offices until 1936, he was transferred to the general offices at San Francisco. His company became a part of Bethlehem in 1930. From 1936 to 1945 he was assistant to the general manager of sales.

Orin P. Walker replaces Mr. English as manager of commercial research. Mr. Walker was formerly assistant sales manager of Petroleum Equipment International and shortly after this company was acquired by Bethlehem, joined its commercial research staff.

Shoreside Personalities

Edward Valves Promotion

Raymond A. Durand, formerly assistant sales manager of Edward Valves, Inc., East Chicago, Indiana, has been advanced to the position of sales manager effective March 1, it was announced by W. F. Crawford, president of the company. He has been a member of the Edward engineering sales organization for more than nine years.

Changed to Harper Packing Co.

James A. McPeak and Raymond P. Farrell, formerly president and treasurer, respectively, of France Packing Company, Tacony, Philadelphia, are now associated with the Harper Packing Company, Inc., Chester, Pa., in a managerial and financial capacity. These new officers bring a combined total of fifty years' active experience in consultation, design and protection of metal packings for engines and compressors.

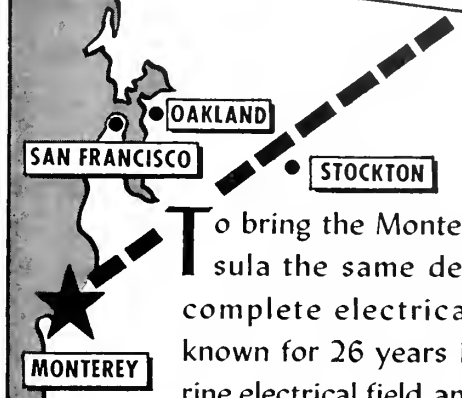
SOON in Monterey!



To bring the Monterey Peninsula the same dependable, complete electrical service known for 26 years in the marine electrical field, and now also serving California's industries, businesses, homes and farms.

Ets-Hokin & Galvan will establish a Monterey Peninsula plant and office at 484 Washington Street, Monterey, about July 1st.

As in six other major areas of the State, this plant will be completely equipped and staffed for every kind of electrical work—construction, repairs, supplies and C-O-TWO Fire Protection Equipment and supplies.

SINCE 1920

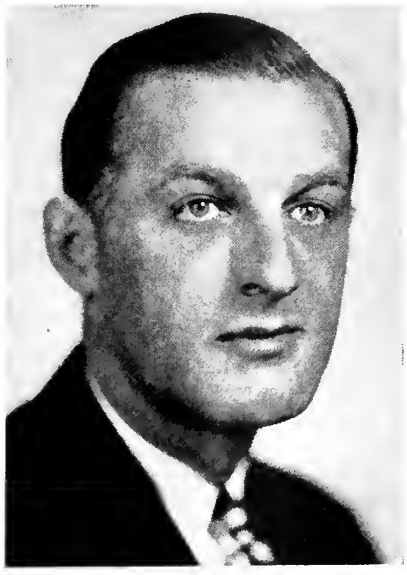
SHORESIDE PERSONALITIES

The appointment of **HOWARD N. MIDDLETON,** of the War Shipping Administration, as Pacific Coast manager of the San Francisco branch offices of Funch, Edye & Co., Inc., of New York was announced recently. Mr. Middleton, former secretary of the Pacific Westbound Conference, resigned his post as WSA West Coast traffic manager on March 15 to take up his new office.

C. E. SORAPURE, vice president of the company, said offices would be opened as quickly as suitable space can be obtained.

The company is an old established New York firm of ship agents and brokers. On the East Coast, it represents the Java-New York Line, Scandinavian-American Line, Royal Netherlands Steamship Company and other steamship firms. Its proposal to expand to the Pacific Coast evoked wide interest among old-established transpacific operators and shippers.

DAVID P. PENHALLOW of Honolulu has been appointed temporarily to the staff of Matson Navigation Company in a general consulting capacity principally to assist in the coordination of operational practices on the Pacific Coast and Hawaii, it was announced by **Hugh Gallagher,** Matson vice president. Mr. Penhallow, a lieutenant colonel now on terminal leave from the Army, served as director of cargo and passenger control in Honolulu.



John Stein

R. F. BURLEY, freight traffic manager, announced that **JOHN A. STEIN** has been reappointed as general freight agent for Pope and Talbot, Inc.

During the war, Mr. Stein served as a major at Fort Mason and had charge of the supervision of cargo handling on ships in the Bay Area and movement of critical war materials overseas.

Mr. Stein has been associated with Pope & Talbot interests since 1923 and had, until joining the service, held the post as general freight agent from 1936 to 1942.

R. J. ETIENNE, vice president of the Cyclops Iron Works, announced the appointment of **JOHN D. MARINE** as sales manager of that company.

Mr. Marine is graduate mechanical engineer and has long experience in sales and engineering of steam power, heating, air-conditioning, refrigeration and cranes.

THE RETIREMENT OF AUSTIN W. SPERRY from the Crane Company took place on February 1, 1946 after a record of 37 years' faithful service, during which time he has been a familiar figure in marine and club circles around the San Francisco Bay Area. Now he is following agrarian pursuits on a nice little "ranch" of six acres near Los Gatos, California.

His rich dramatic baritone has endeared him with members of The Family, Bohemian and, as many of our readers can testify, the Propeller Club and The Mariners Club in San Francisco. Austin is assuring his many friends that they will continue to see him around the customary maritime activities.

CAPT. H. J. TIEDEMANN, USMC Pacific district operations officer of San Francisco, announces that merchant seamen must apply for upgrade training within seven days of their last discharge, to become able-bodied seamen.

Enrollees at the Upgrade School are paid at the rate of $153 monthly. Applications for enrollment may be made at the USMS Enrolling office, 1000 Geary street, San Francisco, where full information can be obtained.

Left to right: R. M. Campbell, Earl Morris, James Glass, Jr., and John H. Schmid, all with Zurn Manufacturing Company.

ZURN NAMES VICE PRESIDENTS AND DISTRICT REPRESENTATIVE

Promotion of **James Glass, Jr.** to vice president in charge of sales and **John H. Schmid** to vice president in charge of engineering, and **Robert M. Campbell** to manager of advertising and sales has been announced by **Melvin A. Zurn,** president of the J. A. Zurn Mfg. Co., Erie, Pa. manufacturers of building, plumbing, drainage, marine and industrial products.

Mr. Glass has been associated with Zurn for more than twenty years in production and sales and was in charge of the Buffalo office.

Mr. Schmid at Zurn for seven years, was formerly with the engineer department of E. I. DuPont de Nemours & Co.

Mr. Campbell has been with Zurn for three years, coming from Benton and Bowles, Inc., New York.

Appointment of Earl Morris as district representative in charge of the Los Angeles office has been announced by Melvin A. Zurn, president, J. A. Zurn Mfg. Co. Mr. Morris has been with Crane Co., Los Angeles branch for sixteen years, and when he left was head of the Marine Department in that branch. Mr. Morris has offices at 10509 Montara Ave., Southgate, Los Angeles, Calif.

PRESENTED WITH SEASCAPE

Vice Admiral Emory S. Land, former War Shipping Administrator, being presented with an oil painting, the work of Captain George Eckstram, veteran Grace Line skipper. Presentation of the canvas is being made by Mrs. Isabel Peterson, director of United Seaman's Service Art Exhibition in which Captain Eckstram's paintings have won wide acclaim.

Appointment

H. F. Gelhaus, manager of the sales division of Todd Shipyards Corp., has announced the appointment of **George W. Peterson, Jr.,** to the sales division of that corporation. Peterson will assist Mr. Gelhaus in the San Francisco office.

Mr. Peterson is well known in Coast shipping circles, and prior to his present appointment was with the former Todd California Yards and Swayne & Hoyt Ltd.

Hot Off the Press

THE COOPER-BESSEMER CORPORATION of Mount Vernon, Ohio, has published three bulletins by B. C. Thiel, consulting engineer for the company. One is entitled "Calculating Pipe Sizes for Compressor Cylinders," a reprint by the company through the courtesy of the author and of the publication, The Petroleum Engineer. The treatise covers a new method of determining diameter of suction and discharge lines of a reciprocating compressor cylinder used at a leading oil field.

Another bulletin is entitled: "Controlled Water Jacket Cooling Reduces Maintenance Costs," a reprint through the courtesy of Petroleum Refiner; and the third bulletin is on "Modern Compressor Stations," which subject was originally treated in Oil and Gas Journal.

STOW MANUFACTURING CO. has put out manual No. 645C on flexible shaft remote valve operating gear. This manual supersedes Book 449 and other previous information related to the subject, and this manual is intended to serve as a guide in the selection, installation, and use of flexible shafting for remote controls for valves and all types of equipment actuated by rotating shafts. The manual is filled with graphs, charts and cutaway drawings of core construction, casing construction, remote control shaft components and every type of installation and assembly gadget.

A BOOKLET ON NORDBERG'S SINGLE ACTING DIESEL ENGINE has recently been distributed by the Nordberg Mfg. Co. of Milwaukee, describing the engine's use for marine service with direct or gear drive and for stationary installations, either oil or gas burning design. Illustrating the bulletin are blueprints of the equipment and photographs.

SHORESIDE PERSONALITIES

CAPTAIN WILLIAM E. PORTER, USMS, former master of the USMS training ship **American Seafarer,** has been appointed chief information officer for the training organization, WSA, replacing Lieut.-Comm. Louis Rosenbush, Jr., Commodore Telfair Knight, Commandant, USMS, announced. At the outbreak of the war Captain Porter was called into active duty and assigned to the Maritime Service as instructor in navigation at the United States Maritime Service Officers' school at Fort Trumbull, New London, Conn., In 1943, he was transferred to the United States Maritime Officers' school at Alameda as executive officer of that base and later assumed command of the American Seafarer.

ADVISORY COMMITTEE OF THE PROPELLER CLUB OF THE UNITED STATES

Seated, l to r: Lewis D. Parmelee, vice president AGWI Lines and pres. Propeller Club, Port of New York; Arthur M. Tode, honorary pres., the Propeller Club of the United States; John F. Gehan, vice pres. American Export Lines and National President of the Propeller Club; J. Lewis Luckenbach, pres., American Bureau of Shipping, and chairman, American M. M. Conference Committee; Harman Lewis, pres., Alcoa Steamship Co., and vice pres., Port of New York Propeller Club.

Standing, l to r: Henry F. Markwalter, v. p., Luckenbach SS Co.; Roger E. Montgomery, pres. and gen. mgr., National Marine Expositions, Inc.; Benn Barber, Admiralty Attorney, Waterman Steamship Agency; Henry Reed, Insurance Co. of North America; O. B. Whitaker, mgr. Marine Sales, Sperry Gyroscope Co.; Harold J. Hording, natl. secty., The Propeller Club of the United States.

New Helmsman at Kings Point

Commodore Richard R. McNulty, USNR, has been appointed Superintendent of the United States Merchant Marine Academy, Kings Point, New York, the War Shipping Administration announced.

Commodore McNulty will succeed Rear Admiral Giles C. Stedman, USNR, who has resigned at his own request to return to private industry after having served as Superintendent of the Academy for the past four years.

The change becomes effective March 31, 1946.

Commodore McNulty will continue to serve as Supervisor of the United States Merchant Marine Cadet Corps, which position he has held since the founding of the Corps in 1938.

Commodore McNulty was appointed Superintendent of the Academy by Commodore Telfair Knight, USMS, Assistant Deputy Administrator in charge of Training, under the authorization of Granville Conway, Acting War Shipping Administrator.

BOOK REVIEWS

SEA, SURF, AND HELL,

Written by A. J. Liebling, Tom Treanor, Edwin C. Hill, (Prentice-Hall, Inc. $3.00).

Edited by Commander Arch A. Mercey, USCGR, and Lee Grover, Ch. Sp. USCGR, here is the stirring history of the fighting Coast Guard. The narrators have spun fine, factual tales of the achievements of men who served valiantly and well on every sea—and on most fighting fronts.

DESTROYERS IN ACTION

Written by Richard A. Shafer (Cornell Maritime Press, $2.50).

Toughest, most daring and dangerous of all Navy service in time of war is the lot of the courageous men who manned our destroyers—and this is their story. It's full of drama and action—well illustrated.

NECROLOGY

JOHN JACOB BROWN, 73, chairman of the boards of Foster Wheeler Corporation in New York, and in St. Catherine, Ontario, Canada, passed away in St. Lukes Hospital, New York on February 15 after a brief illness.

Born in Tyler, Texas, and after a private school education, he started business career as a construction engineer for the Consolidated Compress Company of Texas in 1895. Later he became associated with the Worthington Pump Company of New York as specialist on the development of hydraulic equipment for compressing cotton. In 1907 he became vice president of the Wheeler Condenser and Engineering Company and the Power Specialty Company, N. Y., and was elected president in 1918.

Upon consolidation of the Wheeler Condenser and Engineering Company as the Foster Wheeler Corporation, Mr. Brown was elected chairman.

The late J. J. Brown.

In 1923 he organized the Carteret (N. J.) Bank & Trust Company and served as its president until 1928. He was a director of Fidelity Union Trust Company of Newark, Cranford Trust Company and was a director of many other companies in the East. He was a member of the American Society of Naval Architects and Marine Engineers, the American Society of Mechanical Engineers and many engineers' and bankers' clubs.

S. F. Businessman Passes Away

Howard Mathew Tayler, 59, president of Tayler and Spotswood Company, died of a heart attack recently. A native San Franciscan, he was a member of the Olympic Club, San Francisco Rotary Club, the OPA advisory committee representing steel jobbers on the Pacific Coast, and was a past master of San Mateo Lodge 226, Free and Accepted Masons.

SHORESIDE PERSONALITIES

THE NORDBERG MFG. COMPANY announces the appointment of John G. Earle as special representative of its heavy machinery division. His work will largely be devoted to diesel engines with which he has had wide experience during his many years of association with the diesel field. Prior to his new position he was head of the diesel engine section of the U. S. Maritime Commission and previous to that was with the diesel division of Baldwin Locomotive Works. His headquarters will be at the company's New York office, 60 East 42nd Street.

Captain Ronald T. Strong has rejoined the Westinghouse Electric Corporation as manager of its San Diego office.

"STEAM-DETERGENT CLEANING WITH OAKITE SOLUTION-Lifting Guns," a 28-page booklet issued by the Oakite Products. Inc., New York, tells of the four major applications of steam-detergent cleaning: maintaining processing equipment to comply with sanitary regulations: cleaning machinery to facilitate subsequent rapair; preparing surfaces for repainting or refinishing; cleaning equipment too large for tank immersion, or where tanks are not available.

It also tells of case histories of many divergent industries that have used this method of cleaning.

THE SPERRY GYROSCOPE COMPANY, Inc., Great Neck, New York, has issued a booklet, "Rudder Angle Indicator" (Publication 18-5), telling of the extensive tests made on Sperry equipment in the laboratory and on board ship. The illustrations include line drawings of the rudder angle equipment arrangement, the rudder angle transmitter, and the 115 and 230 volt dynamotors.

NEWLY ISSUED IS THE "ARNOT SLEEPER," an attractive two-color booklet put out by Arnot and Company, Baltimore. This booklet shows how the versatile Arnot Sleeper can be used in homes, ships, and trains.

JUST OFF THE PRESS is the new 27-page booklet on opposed-piston diesel engines issued by Fairbanks Morse & Co., Chicago. Well illustrated, the booklet contains a two-page, four-color spread of the Model 38D8-1/8 Fairbanks Morse opposed piston diesel engine.

"EMERGENCY CUTTING," recently issued by the Victor Equipment Company of San Francisco, tells of the Pack Type Emergency Cutting Outfit for fire fighting originally designed and produced for the Navy.

FROM THE INDUSTRIAL LINING ENGINEERS, INC., Edgeworth, Penn., comes a four-page folder called "Lining for Industrial and Process Equipment." It contains a helpful comparison-chart of the different linings now in use.

THE STORY OF THE COCHRANE SAFETY RELIEF VALVE is told in Cochrane's new publication No. 4150. Of special interest is the revised "Sizing Data on Relief Valves" which includes capacity and pressure rise tables for size selection.

THE VICTOR EQUIPMENT COMPANY, of San Francisco, has issued its 1946 fully illustrated catalogue of welding supplies.

THE PHILIP CAREY MANUFACTURING CO., Lockland, Ohio, has just released a revised edition of their heat insulation materials catalog, "Heat Insulation for Industry." It has been developed to facilitate the specification and purchase of heat insulation for industrial and commercial use.

Balanced ROPE
MUST HAVE ALL FIVE..
Waterproofing
ENDURANCE
FLEXIBILITY
APPEARANCE
STRENGTH

Balance is the first essential in good rope. COLUMBIAN makes its rope with perfect balance. Equal emphasis is put on all five features. A slicker, whiter appearance, for example, would be attained at the sacrifice of adequate waterproofing. This sacrifice is never made at COLUMBIAN.

WATERPROOFING. Every fibre is individually waterproofed and lubricated! Each fibre is thus sealed against decay, and the resulting rope is more flexible ... easier to handle even when wet! COLUMBIAN waterproofing adds to the non-kinking properties of the rope, and extends its life and service. Adequate waterproofing is vital to the production of Balanced COLUMBIAN Tape-Marked Pure MANILA ROPE.

COLUMBIAN ROPE COMPANY
400-90 Genesee St., Auburn "*The Cordage City*," N. Y.

Columbian TAPE MARKED PURE MANILA ROPE

THANK YOU LADY!

Yes, we thank the lovely lady in the illustration for posing so gracefully with that fine Manila Rope in which she is so enthusiastically entwined.

Unfortunately, however, the supply of Manila fiber is still extremely limited and it will probably be some time before Manila Rope will come out of the "scarce" class.*

You may be sure that this organization is doing everything possible to hasten the day when you can once again get all the Manila Rope you want from your supplier.

One thing you may be sure of—when you see the famous trade mark of Tubbs Extra Superior Manila, it will be a rope built to highest standards of perfection and made from only the very choicest Manila fiber. *It will be a Rope worth waiting for!!*

* Even though government regulations permit the making and use of Manila rope (3¾" circ. and larger), fiber supply is far insufficient to fill the demand.

SOMETHING TO LOOK FORWARD TO—THIS FAMOUS ROPE TRADEMARK.

For "Cold-Water Casualties"

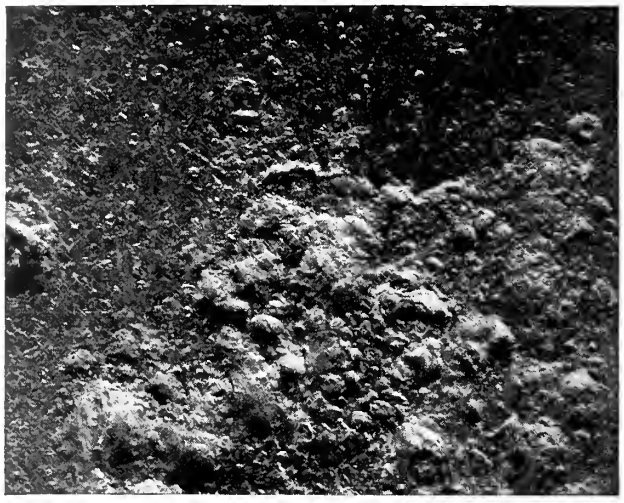
APEXIOR-NUMBER 3 has many valuable uses in the maintenance of ships' hulls and equipment, providing lasting protection for all metal surfaces exposed to fresh or salt water at temperatures under 125°F.

Applied to submerged stern areas, this durable protective coating eliminates water-to-metal contact, keeping pitting and corrosion to a minimum. And since APEXIOR NUMBER 3 is non-conducting, it also checks electrolytic corrosion due to the proximity of bronze propellers to steel hulls, affording protection to rudders, rudder posts, tail shafts, and struts. (No anti-fouling properties are claimed).

APEXIOR NUMBER 3 retards corrosion on ventilators and life-boats, on the cooling water sides of condenser tubes, in condenser water boxes and in many other applications above and below decks. It is effective on every type of cold water tank and, being non-toxic, is entirely suitable for the interiors of drinking water tanks.

In regular use by leading steamship companies for many years, brush-applied APEXIOR coatings are daily proving their high protective value. Adequate stocks are available in all important ports.

And "Victims Of Boiler Water"



APEXIOR NUMBER 1, brush-applied in a few thousandths of an inch thickness, forms a mechanical barrier between boiler metal and water or steam at all temperatures and pressures.

This tough shield over all pores and joints checks corrosion and resists the action of oxygen and entrained gases. A good heat conductor, it aids in maintaining thermal efficiency by retarding the formation of operating deposits and preventing them from bonding tightly in insulating layers. The surface of APEXIOR NUMBER 1 is chemically inert; any operating deposits form a mechanical bond only, and are easily removable.

APEXIOR NUMBER 1 is unaffected by boiler pressures and ratings, varying feedwater conditions or chemical treatments. Its regular use in engine and boiler rooms, wherever metal parts are exposed to hot water or steam, is followed by increased over-all operating efficiency. In common with APEXIOR NUMBER 3, it lengthens the service life of metal and reduces maintenance labor and costs in all applications.

Free Marine Service Manual will give you full information on the marine uses of APEXIOR protective coatings. The Dampney Company of America, Hyde Park, Boston 36, Massachusetts. Marine Dept., *East Coast:* 114 Liberty St., New York 6, N. Y., *West Coast:* C. C. Moore & Co., San Francisco, Cal.

Two new high-temperature Dampney coatings are Thur-Ma-Lox Number 7 Black (1600°F.) and Thur-Ma-Lox Number 10 Aluminum (1200°.) Properly applied, they provide lasting protection to dry metal surfaces subjected to the extreme temperatures indicated.

Who Will Speak for Shipping?

Pacific MARINE REVIEW

The most important natural asset of any port city, and the back country which supports it and which it supports, is its shipping facilities.

Removal of our harbors would decrease the value of every piece of property in the port area, reduce the dollar volume of every business enterprise, and in a very short time reduce the number of jobs and the dollar income of every resident.

Yet we find that the general public and its representatives, from government bodies down through chambers of commerce and civic groups of all kinds take a lackadaisical if not scornful attitude toward our shipping and harbor trade when they should be concentrating their best efforts toward seeing that the port business is protected. Men who would protect with their lives their families and their homes will permit a primary source of their families' income to be jostled into disrepute and thereby destroyed.

Sound public relations—the depicting of that point where the public and industry have a common interest—should be and must be developed. The biggest men in every port community should be the spokesmen for their harbor and shipping and spokesmen should speak up. They should be alert to recognize that delays and frustrations to vital projects are due to either lack of knowledge — or opposing propaganda.

A clear statement of essential facts will usually win over the ignorant. The interminable argument in council chambers and committee meetings will be minimized when **facts** are made known.

Opposing propaganda is something else. We find our industry attacked by other industries, by political theorists, by government bureaus, by segments of itself. And, negatively, by failing to provide needed legislation or by lack of cooperation. Alertness to detect opposition, ability to dramatize the public's stake in the industry's welfare, and integrity before attack are the elements of sound public relations. The government could use these attributes and win public support by just **stating** a policy. The maritime industry can use them—plenty.

No man is too big for this job and no other interest should outrank it.

Alcoa Cargo-Passenger Liners

COMPLETED IN WEST COAST YARD

Three Victory type hulls under construction at the Oregon Shipbuilding Company, Portland, Oregon, for the Martime Commission are being converted into a special type of cargo-passenger liner for the Alcoa Steamship Company. They will be fitted for the South American trade carrying general cargo south-bound and bauxite ore northbound. Luxurious accommodations for 97 passengers are arranged on the promenade deck.

The design of the conversion features is being handled by George Sharp, naval architect, New York. The joiner work is being installed by Buckler-Chapman of Portland, Oregon, using the Martin Perry type of bulkhead. The official designation of these vessels as Victory type cargo carriers is AP-3; as Alcoa cargo-passenger liners they are designated AP-7. Table 1, herewith, gives principal characteristics of the hull and Table 2 sets forth the loading capacities both for general cargo and for bauxite ore. Drawings show the arrangement and self-trimming features of the bauxite loading and of the refrigeration and general cargo loading.

Propulsion Machinery

Two Maritime Commission water tube boilers (fitted with super heaters, desuperheaters, air preheaters, economizers and force draft blowers) supply steam at 450 psi 750° F. to a Westinghouse compound turbine connected to the single propeller shaft through Westinghouse double reduction gearing. Engine room is amidships and has the usual long shaft alley with tanks port and starboard. An unusual feature for American hulls and one found only in the Victory type is the full use of the Contra-Propeller system in the design of the ship's stern. The structure of the ship in way of the stern frame and the run aft is formed into ideal curves to make that portion of the hull a Contra-Propeller. Theoretically this should make a decided increase in the propulsive efficiency of these hulls. So far as our knowledge goes no data on this expected improvement have yet been published by the Maritime Commission.

The usual arrangement of Maritime Commission engine rooms prevails. One space houses the two boilers, the turbine and its gears, and the auxiliary machinery. A turbine drive feed pump is installed in the location usually given to the reciprocating feed pump and the latter has been relocated. Two 300 kw Worthington turbo-generators are installed to take care of the electrical load in cooking, ventilation, pumps, refrigeration, and lighting.

Table I Characteristics AP-7

Length Overall	455′ - 3″
Length B. P.	436′ - 6″
Beam	62′ - 0″
Draft Loaded, Max.	28′ - 6″
Total Deadweight 28′D	9360 Tons
Cubic Capacity General	375,420 cu. ft.
Cubic Capacity Refrigerated	16,000 cu. ft.
Propulsion Power	8,500 shp
Normal Sea Speed	15 Knots

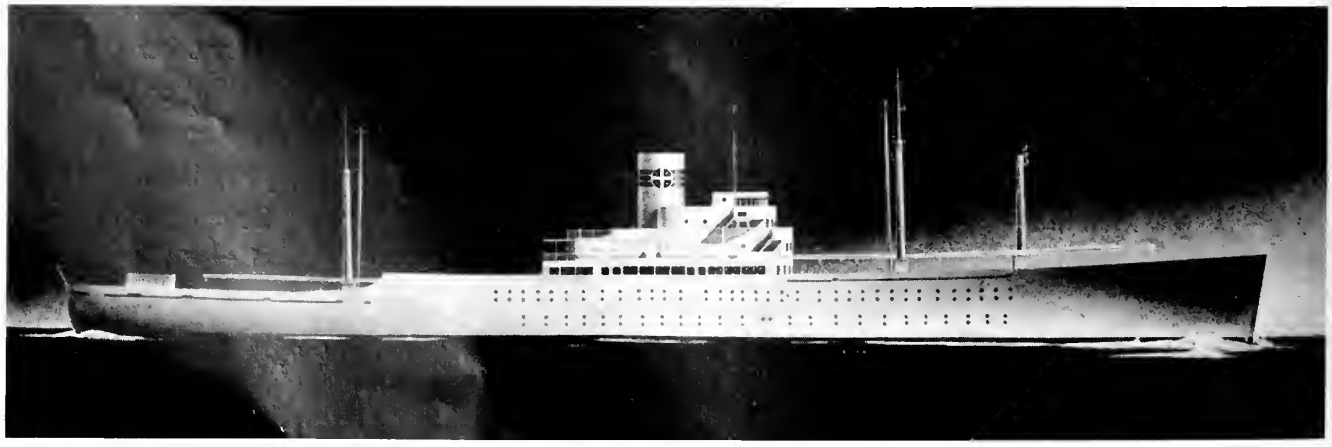
Combustion in and feed water to the boilers will be under automatic control.

Spaces immediately aft of the engine room port and starboard of the shaft alley are used for general service pumps on the port side and on the starboard side for a well-equipped machine shop and a room for a battery of CO_2 cylinders to take care of fires in engine room and other spaces.

Flats in the engine room support the turbo-generating sets and the electrical switchboard on the starboard side and the refrigeration and air conditioning units on the port side.

These vessels are designed: to carry a considerable volume of refrigerated

Artist's drawing of the new Alcoa Victory type ship. A point of special interest is the large port door leading to refrigeration holds. The door is dimly outlined in the picture near the center of the lower rows of portholes.



cargo; to take care of the refrigerated stores for 97 first class passengers and for the crew; and to provide air conditioning in all quarters both for crew and passengers.

Cargo Handling

There are five cargo holds—three forward of machinery space and two aft. Hatchways serving these holds are uniformly 22′ 4″ wide and from bow aft have lengths of 25 feet, 33 feet, 30 feet, 36 feet and 45 feet. Double king posts are installed between hatches: No. 1 and No. 2; No. 2 and No. 3; and No. 4 and No. 5. No. 1 king post is fitted with two five ton 55 foot booms; No. 2 king post with two five ton 55 foot booms on the forward side, and on the after side two five ton 55 foot booms and one 50 ton 60 foot boom; and No. 3 king post with two five ton 50 foot booms and one 30 ton 60 foot boom on the forward side, and two five ton 50 foot booms on the after side.

Twelve U. S. Maritime Commission unit type cargo winches driven by 50 hp Westinghouse motors take care of the lifts on these booms.

Refrigerated cargo is carried in insulated spaces on the first platform deck and hold levels immediately aft of Hold No. 3. At the hold level there is one large refrigerated cargo compartment stretching right across the vessel. Above on the first platform is another cargo compartment at the starboard side and on the port side three refrigerated rooms for ship's stores—a meat room at 5° F., a fruit and vegetable compartment at 35° F., and a dairy products chamber at 32° F. Directly above these on the second deck are three insulated chambers—a butcher shop which is held at 45° F., a fish room maintained at 5° and an ice storage box at 25° F. All of these insulated spaces as well as the steward's dry stores and the slop chest are loaded and unloaded through a thwartship passage and side ports port and starboard at second deck level. Opening off this passage are two vertical con-

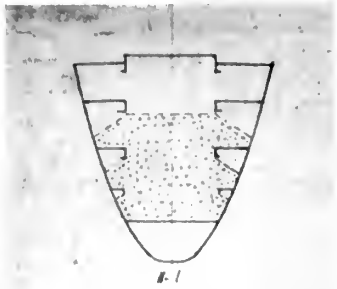
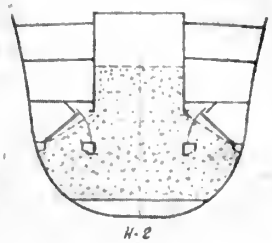
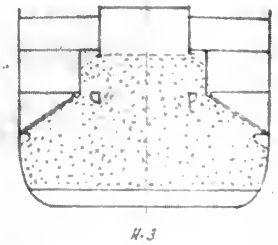
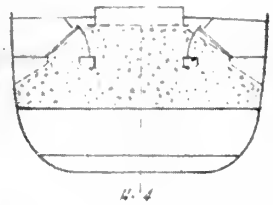
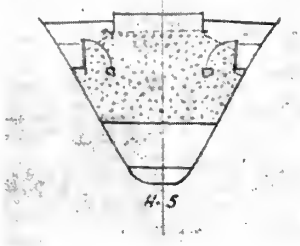
SECTIONS SHOWING SELF TRIMMING ARRANGEMENTS IN HOLDS

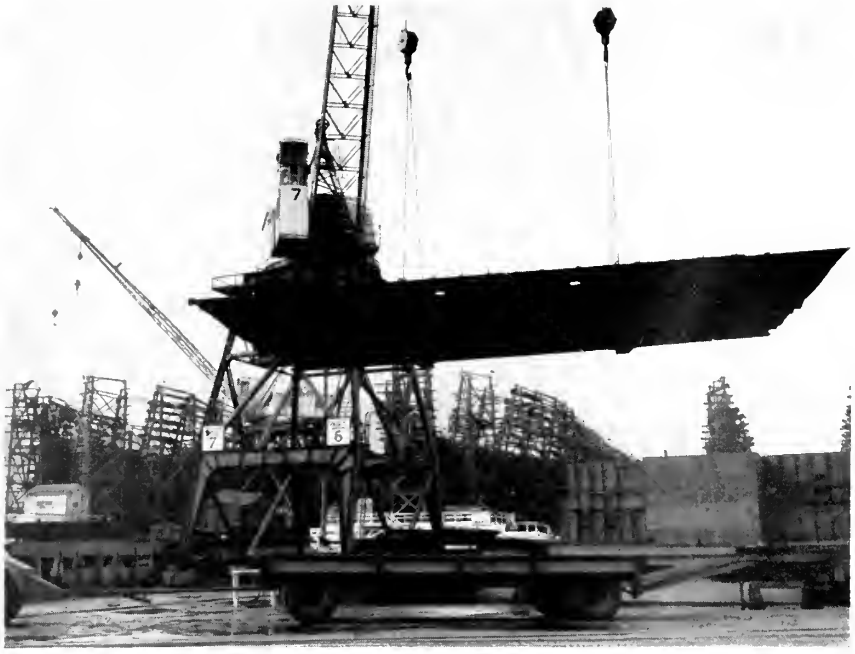












Like old times. (Well, not quite, but section lifts like this are not uncommon now that Oregon Ship is in production on the three luxury liners under construction for Alcoa.)

veyors or elevators with platforms about 5 feet square so that hand truck loads may be carried with the longshoreman. The trunks through which these conveyors operate open onto second deck, first platform deck and hold levels.

At the second deck level trimming hatches for bulk bauxite ore are fitted in way of cargo hatches 3, 4, and 5, and similar trimming arrangements are fitted in first platform deck in way of cargo hatch No. 2. The sectional drawings herewith illustrate the character of these arrangements.

Passenger Accommodations

Passengers are all housed on the promenade deck, the main deck, and the sun deck. On the main deck are bedrooms with a total capacity for 84 passengers; also the main galley and dining saloon. The promenade deck has public rooms surrounded by an enclosed promenade. A palm court occupies the forward end of the house enclosure. Opening off this court port side is the purser's office and a store and a stateroom and at the starboard side a large suite. Aft of the palm court port and starboard of the machinery casing are respectively a club room and a lounge, aft of these on the open deck is a nice built-in swimming pool amidships and deck game spaces port and starboard. On the sundeck in the forward end of the house are two beautiful suites each occupying a space 14 x 21. These form a very unusual feature inasmuch as they are on the deck above the officers' quarters and directly beneath the pilot house. All of the staterooms have private bath or shower and private toilet and all are airconditioned with regulation in the hands of the passenger.

Crew's Quarters

Accommodations for the officers are unique in that all licensed officers, deck and engine room, are housed on the boat deck; engineers on port side; and deck officers on starboard. The rooms for the chief are identical with those for the master, first assistant same as first officer, and so on. Only a fore and aft passageway on the centerline of ship lies between them and since this passageway ends at the after bulkhead of the captain's office and opens into that office there is a difference of four feet in thwartships dimensions of the captain's office and that of the chief. Aft around the machinery casing on this level are two deck cadets, the purser and the junior third officer on the starboard side, and two engineer cadets, the chief electrician and the junior third engineer on the port side. We are glad to see the engineer force moved up top side and think it should do much for the morale of the whole crew. All the rest of the crew are housed on the second deck in nice rooms. All crew quarters are air conditioned and ample provision of toilets, showers and baths is installed.

Aluminum

The entire superstructure above sundeck level including the outer casing of stack will be of aluminum. All lifeboats and lifeboat davits will also be of aluminum. Boats, davits, and boat winches are by Welin. Accommodation ladders will also be aluminum.

Navigation equipment will include all the most up-to-date devices including a full installation of radar.

The estimated cost of each vessel is around $4,000,000. Completion dates are tentatively set for September 5, 15 and 25, 1946.

Famous Old Four-Masted Barque Modernized With Diesel Power

Recently the Portuguese barque Foz Do Douro appeared on the high seas cruising along at 15 knots with her sails furled and Diesel engines furnishing the propelling power and not the wind. That is because not so long ago she was taken in by the Kensington Shipyard and Drydock Corporation of Philadelphia, Pa., and fitted out with a pair of Fairbanks-Morse Diesels and a full complement of required auxiliary equipment.

It was not a simple job, yet it was done with neatness and dispatch so characteristic of the type of work the Kensington yards are prone to do. Furthermore it was a most interesting installation, not only the conversion from wind to motor power but also the application of twin screw Diesel drive.

When the task was finished the officials of the shipyard were highly pleased—it hadn't been easy and time was limited for at that moment the war was still raging and she was

urgently needed for conveying prisoner of war supplies for the American Red Cross to the unfortunate inmates of prisoner of war camps in Germany. But if the shipyards folk were pleased, to say that the owners of the Foz Do Douro were pleased, would be putting it mildly.

Letters and cables were sent by her skipper and her owners telling of the satisfactory performance of her twin Fairbanks-Morse Diesels, their ease of operation and the splendid maneuverability of the motor vessel. "On her first Atlantic crossing, she acted very satisfactorily," writes Chief Engineer A. Moreira. "She averaged, heavily laden with cargo, 9 knots with a daily fuel consumption of only 35.8 barrels."

The voyage, with full cargo, was accomplished without aid of sail.

Historically the Foz Do Douro is most interesting. She will be remembered by many a captain and crew on the seven seas as the Abraham Rydberg, the training ship of the Swedish Merchant Marine. She was built in Scotland in 1892.

Since that time she has been in various trades, under Hawaiian, United States, Swedish and Portuguese flags. In 1925 she established a record for sailing ships by making the voyage from San Francisco to Unalaska, some 2400 miles in 7 days for an average speed of approximately 15 knots. Today she flies the flag of Portugal, out of Oporto, Julio Ribeior Campos, owner.

The principal dimensions are: registered length 260′ 9″, molded beam 43′ 2″, depth 23′ 6″ and of 2323 gross tons. The vessel has a steel hull and her sailing gear is that of a 4-masted barque.

The new main propulsion plant consists of twin 690 hp 300 rpm Model 37E14 Fairbanks-Morse two cycle Diesel engines embodying such features of design and construction as oil-cooled pistons, open head combustion, differential injection valves and back-flow scavenging—a design which originated by Fairbanks-Morse has been found most dependable in marine service.

The main generator is of 40 kw capacity, 115 volt dc marine type, drip proof and is direct connected to a 60 hp, 6-clinder Model 36 Fairbanks-Morse full Diesel engine. operating at 1200 rpm.

A 20 hp, 2-cylinder Model 36A4¼ Fairbanks-Morse Diesel 1200 rpm, operates the auxiliary air compressor and the general service pump. To the fore end of this auxiliary Diesel power plant is clutch-connected a Watreous 2½″ rotary fire, bilge and general service pump of 150 gpm capacity at 100# pressure. Also clutch-connected to the aft end is a Gardner-Denver ABD, 2-stage water-cooled 40 cfm, 250# air compressor. A 20 kw, 125 vdc variable speed, marine type tail-shaft generator is also provided.

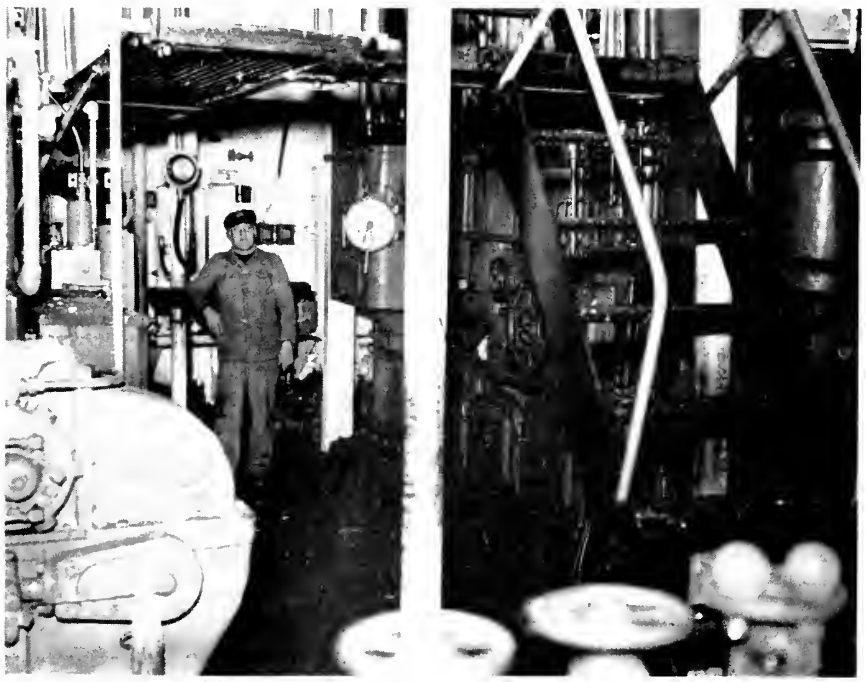
Other pumping equipment includes the following: two Fairbanks-Morse, motor-driven units, push button controlled, consisting of a 405 gpm centrifugal circulating pump for salt water and one 120 gpm lube-oil circulating pump. Two fresh water circulating pumps are also provided. These are 4″ suction, 3″ discharge, motor-driven centrifugal pumps driven by 7½ hp 115 volt, direct current marine type motors. Both pumping units are of Fairbanks-Morse make.

The complete engine room is nicely laid out with plenty of head room and space for the engineer's crew to move about comfortably.

All in all the conversion of the Foz Do Douro to Diesel power has been a happy circumstance to all concerned.

The Foz Do Douro

The Foz Do Douro's engine room.



The American Merchant Marine or The Merchant Marine and Government

John E. Cushing, who returned to his steamship company position the first of the year, is regarded as one of the best informed ship operators in the country. In the following article, a synopsis of his address before the San Francisco Propeller Club, and in the article on Page 391, a synopsis of an address before the San Francisco Foreign Trade Association, Mr. Cushing gives the industry its first over-all insight into the future of the steamship business.—Ed.

By John E. Cushing

President, American-Hawaiian Steamship Company and former Deputy Administrator for Pacific Ocean Areas, War Shipping Administration, World War II.

John E. Cushing

Throughout our industry today, we hear a lot about return to private operations, restoration of the open market, lifting of government restrictions and freedom of enterprise. They are all fine sounding phrases and they help make fine sounding speeches. Yet I wonder if right now in this transition period, it isn't the proper time to take a good hard look at them realistically, instead of accepting them casually, at their face value as we are so prone to do with statements we are glad to hear.

Please understand that I do not for a moment question the sincerity of those who make the statements and speeches to which I have referred. But I do question whether they have ever applied or can ever apply to merchant shipping. The one shipping operation which might successfully claim complete freedom of interference from governmental controls was that conducted a couple centuries ago in the Caribbean, by certain gentlemen of many races. Its most successful operator was one Henry Morgan, and it only lasted until government caught up with it.

It so happens that most of us started our shipping careers under the traditions of a time when Great Britain so completely dominated the merchant shipping field that she felt it in her national interest to minimize government aids and government interferences in world trade. That happy period was of brief duration. Roughly, it ran from the 1850's to the outbreak of World War I—say 60 years out of the 460 of Britain's long maritime history. Before that period and after it, her merchant marine was one of the chief instruments of her national policy—consistently fostered and assisted by her government and as always in such cases, equally consistently directed and controlled.

Of all the other maritime nations, I cannot speak with the same assurance, but I do not know of any whose shipping enjoyed even that short respite of absolute freedom. Some of you will undoubtedly say, "What about Norway?" She is in truth a unique case, because with her the building and running of ships,—as distinct from serving her own trades,—is the major factor in her national economy, and in consequence her shipping industry in a perfectly proper sense dominates, and controls her government, where shipping policy is involved.

But when you consider Germany, Japan, France, Holland, Sweden, Denmark, and, above all, our own United States, you will find that their merchant shipping and their governments have been definitely intertwined from beginning to end.

So whatever we mean when we talk of free enterprise in relation to ocean shipping, it is not what we mean when we talk of it in relation to Henry Ford or United States Steel or the grocery store on the corner. Even in our domestic trades, American shipping would not last a figurative five minutes if the flag protection was withdrawn, and most certainly flag protection can only be established and preserved by government.

I guess, therefore, realistically, free enterprise when applied to shipping throughout the world, can mean at most freedom from direct government operation—but with plenty of government interference, regulation, direction and control—as compared to complete socialization where government bureaus initiate, supervise and actually perform the multitudinous activities which go to the running of ships.

If you will accept that guess for a moment at face value, it is interesting to see the widely divergent approaches which the various maritime nations seem to be making toward the

(Continued on Page 448)

The Intercoastal Trade

By John E. Cushing

The intercoastal trade, like many another veteran newly returned from the wars, is back on its old job—but not the same old job. It faces new problems and changed conditions which must be met and solved for the sake of its very existence.

I need not tell you how important it is to the Pacific Coast that these problems find their answer. For almost one hundred years our domestic shipping—intercoastal, coastwise and offshore—has been the basic foundation on which our port developments, our waterfront employment, and our merchant marine itself has rested.

Before the war the protected trades in sailings, cargo tonnage and ships represented more than all the rest of our Pacific Coast shipping combined —year in and year out. With no invidious comparisons, the intercoastal branch of the family was, in many ways the more important. Primarily it is a long voyage trade — 13,000 miles more or less on a round. That meant the ships it employed were of a size and type which could journey anywhere in the world. It meant big cargoes and it supported in our ports the facilities and improvements which big ships and big cargoes require. It is not too much to claim that—cargowise—it was the most important single element in Pacific Coast shipping.

Nationally in another way it proved its worth. In two great wars and a minor one its steamers were the shock troops who took the brunt of supporting our armed forces through the initial stages, in the shipping field. Without the intercoastal fleet in the summer of 1917 and the winter of 1941 our start down the road to victory would have been a definitely slower one. Our deficiency in ships and in trained personnel—afloat and ashore — would have taken much longer to overcome, while we stood idle or on the defensive at home.

The trade has always given the nation a natural reserve of ocean-going ships in actual operation on a route where they are readily available in emergency and plying waters close enough to our coasts to minimize the chances of adverse enemy action.

It cannot, of course, do more than act as a forlorn hope but in that role it has proved its value by actual performance. To meet our new responsibilities we must have a merchant shipping reserve which will probably be substantially in excess of the totals that our active domestic and foreign fleets combined can provide, but no matter how scientifically an immobilized reserve is kept in being, it will take precious time to break it out, to man it, and to get it going. Like everything else in this world a dead ship is no adequate substitute for a live one.

So on two counts—economic and military — the problems of intercoastal shipping are of concern to the nation and more particularly to this Pacific Coast.

Time permits only a brief mention of the part which intercoastal shipping played in World War II. Its record was in the highest tradition of our merchant navy. Many of its ships and—sadly—many of its best men did not return. The ships which did come back are battered and worn with four weary years of the hardest kind of usage. Their age and the beating they took does not justify more than temporary reconditioning. The trade must be retooled on a wholesale basis.

Before I leave the past for the present and the future I ask your indulgence to touch briefly on one intercoastal contribution which has been little publicized as such. In the spring of 1941 the position of the British army in Egypt was critical in the extreme. There was a call for help from London to Washington and help was promised. In those far-off days we were still clinging to neutrality. Under a technical but highly realistic subterfuge—Egyptian neutrality—American ships were asked to do the job. It was largely the voluntary contribution of the intercoastal lines that set up the slender lifeline over which flowed the munitions and supplies which played no small part in saving Suez. Technically every man aboard those vessels could have been summarily hanged in the event of German capture and for once international law would have been with the Germans. Fortunately that did not happen although one of the fleet fell victim to German bombs and many others suffered personnel casualties and physical damage from the same cause.

You are all familiar with the stirring story of the conversion of American industry to the uses of war. In the intercoastal trade it was not conversion. It was obliteration.

A few weeks after Pearl Harbor the trade had ceased to exist. Skilled and specialized organizations which had taken years to build were of necessity dispersed almost overnight. The transcontinental railroads shouldered the added burden of the Canal traffic and as we all know did a magnificent job of handling it.

With the ending of the war the intercoastal lines began to take stock. It needed no Einstein to figure the answer. There was no X in the equation. In terms of simple arithmetic pre-war rates were totally inadequate for post-war costs. The Government could make the intercoastal owners a present of the new ships necessary for retooling and even the most careful operator would have drowned forthwith in a sea of red ink.

Offshore, of course, the problem was met by the simple device of taking the pre-war conference tariffs and adding a percentage surcharge to cover cost increases. In the domestic trades there was no such easy answer. The intercoastal and coastwise operations had come under the jurisdiction of the Interstate Commerce Commission in 1940. The procedures of the Commission to protect the public interest are properly not designed to make hasty, emergency action on rate increases an easy matter. There was

also the complication of the inescapable relationship between rail and water rates and its effect on waterborne cargo volume.

Thanks to the courage and foresight of Granville Conway, acting administrator of the War Shipping Administration, and his associates, the United States moved vigorously and effectively to tackle the problem. Two months after V-J Day a limited number of Victory freighters were assigned by the Administration to the various holders of service certificates in the intercoastal trade on a basis roughly proportioned to the pre-war service of each individual line. Later similar action was taken to re-establish the coastwise services.

It was realized in advance that the experiment would be at taxpayers' expense to a greater or lesser degree, but it was felt there was ample justification for the action. It meant the continued operation of a substantial number of ships — fifty plus, intercoastally — which would otherwise have been forced into lay-up—also at taxpayers' expense. It meant continued employment of officers and crews, of longshore and repair yard labor, in fact of all the manpower and materials which go into an operation of that size. It meant revenue for port facilities and for the Panama Canal—for the most part taxpayers' operations. Finally it meant a demonstration in practical terms of the measure of rate increase necessary if the domestic trades are to be preserved under ultimate private operation.

The next move came in late March when the War Shipping Administration, joined by the Maritime Commission, petitioned the Interstate Commerce Commission to conduct a full investigation of intercoastal and coastwise rates and their relationship to the rates of competing forms of transportation. Bearing out the military interest in the preservation of domestic shipping the War and Navy Departments have urged on the Commission that it act affirmatively and speedily.

Because it so pertinently illustrates this interest, I take the liberty of quoting Secretary of the Navy Forrestal: "Tonnage engaged in coastwise and intercoastal trades is of particular significance from the aspect of national defense. In the event of an emergency, such shipping constitutes a ready reserve for utilization in the immediate solution of such logistic tasks as may require prompt and decisive accomplishment. The nature of the trade makes such tonnage peculiarly important since there exists neither any danger of internment nor any lengthy delay in their availability for emergency service."

I doubt that there is any substantial number of people in the United States who would favor government operation of domestic shipping on any permanent basis. Certainly that does not motivate the officials who are behind the present experiment. It is a stop-gap only but a useful and constructive one. That it is not unpopular with the shipping public has been amply demonstrated by the fact that in spite of all sorts of warborne handicaps, cargo offerings from a scanty and discouraging beginning are now close to a capacity basis in both directions.

It would be presumptuous to anticipate the Commission investigation by making even a guess at the overall percentage of rate increase necessary to put the domestic trades on a paying basis, nor do I want to bother you with a lot of figures. I do feel that you may be interested, however, in a few specific illustrations which I think will clearly demonstrate why there is no need for an X in this particular equation.

To make the cost figures clearer I should first state that in pre-war times an intercoastal turnaround meant anywhere from 80 to 100 days. On the long leg between the Coasts the transit time ran roughly from 17 to 21 days. With the higher speed Victories now running, turnaround has dropped to somewhere in the 70 day bracket and transit time has been reduced to 14 days. All this time saving has been taken into account in the figures which follow and which come from actual experience.

In 1939 the ship wage and overtime bill for an intercoastal round was about $14,000. Today it is $27,000. Pre-war the ship's complement fed for 80c per man per day. Now the figure is $1.37. On the cargo side for almost identical commodity makeups a ton of cargo handled in and out in 1939 for an average of $3.12. In 1946 the same operation is costing about $6.03. Thanks to the skill of the Maritime Commission designers the fuel bill is proportionately less in percentage increase despite the much higher speed. It has risen only 50 per cent with oil prices some 70 per cent higher than pre-war. The much maligned Panama Canal tolls are about the only operating item which stands unchanged.

Overall excluding repairs, insurance and overhead, on which conditions do not now permit a fair comparison, a normal round voyage would run in 1939 at about $85,000. Today it in-

The American-Hawaiian Steamship Company, of which Mr. Cushing is president, has a long record in the intercoastal trade and previously had operated to the South Pacific. The suggestion is made that the company will soon be serving the South Pacific again.

S.S. MEXICAN, dating from 1907, the "Mexican" is one of the oldest ships in service.

volves the expenditure of $150,000 plus and sometimes a pretty big plus. Neither figure carries any allowance for capital charges and both are based on the same totals for cargo tonnage handled.

Before any shipper friends who may be present find their blood pressures unduly rising, I hasten to say that there are certain to be offsetting factors and that any reckoning of rate increase percentages from cost figures alone may well prove misleading. For example we may piously hope at least for a marked improvement in labor performance which was in the depths of its post-war slump during the period covered by the figures. Many of our pier facilities have had to be makeshifts with consequent high piling, double handling, and short room for sorting, all of which make for higher cargo costs. Supplies of all sorts will follow the general market and no governmental control yet devised has beaten the old formula that what goes up must eventually come down.

Finally on the traffic side there are two unknown factors. Pre-war the trade was always out of balance. It took more ships to carry the Eastbound cargo than there was Westbound cargo to fill them. Our own figures year in and year out showed 95 per cent full Eastbound to 62½ per cent full Westbound. Any holding increase in Westbound volume would have a marked effect as an offset to increased costs since it costs about as much to run a full ship as an empty one.

Again the law permits the Commission to establish through rates and routes between rail and water. The war wiped out the water element before this phase had even been explored. I do not believe anyone on either side of the fence can venture a worthwhile opinion on all its implications but properly set up and administered it could mean much by way of added revenue to the participating carriers without any undue hardship to the shipper.

We come now to the retooling problem. Without teaching the highly controversial question of whether the prices established by the Ship Sales Bill can be maintained over any extended period, the bill itself makes no distinction in sales or charter prices between foreign and domestic operation under the American flag. Whether the domestic trades can support the prices prescribed is, of course, just a part of the whole problem of costs versus revenues. A generous interpretation of the trade-in provisions by the Maritime Commission—i. e., credit for old ships turned in against the purchase of new—would be most helpful and in no way against the public interest. The domestic trades would be particularly benefited by a liberal approach since conditions in their field made replacement a practical impossibility in the period between the two wars.

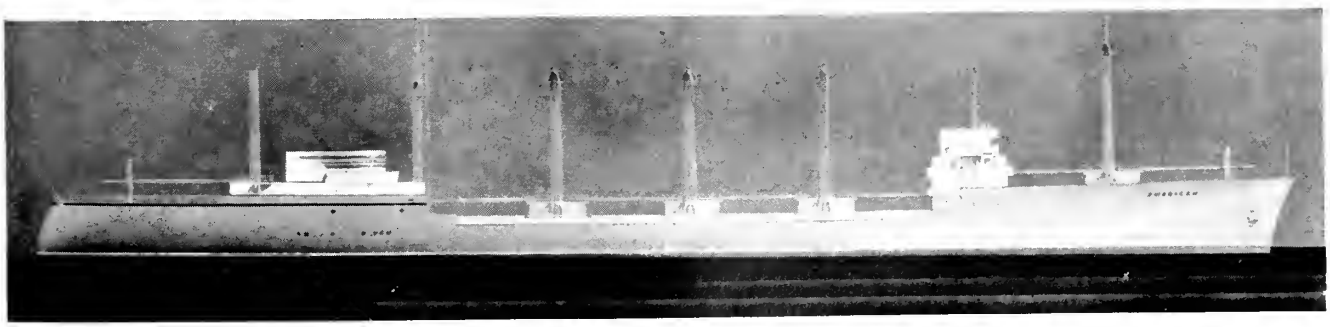
Unfortunately none of the major Maritime Commission types of new construction are ideally suited to the intercoastal operation. They were built and properly so, either as all purpose ships for war use or to meet the special requirements of the subsidized offshore trade routes. They can be made to do but they are not what one would order on one's own account. They will have to do because the Ship Sales formula prices are far below the building price today of a new and specially designed vessel. Unless some new formula can be found, history will repeat itself and an orderly and progressive modernization of our domestic fleets over the next twenty years will be impossible.

From the shipper's standpoint the new tools available should spell improved service. The greater speeds will make transit time more nearly comparable to rail. The war has developed numerous new tricks—though no revolutionary changes—in refinements of stowage and handling. Some of them will unquestionably be adapted to peacetime use. Under stricter regulation, rate wars, rate instability, and the fear of unfair discrimination should be out of the picture. Through billing should simplify the mechanics of water shipment. With cutthroat rate competition out the lines should be able while maintaining keen service competition, to work together in introducing improved claim procedures, minimizing paper work, and even tackling certain phases of marine insurance which tend to make shipment by water more cumbersome than by land.

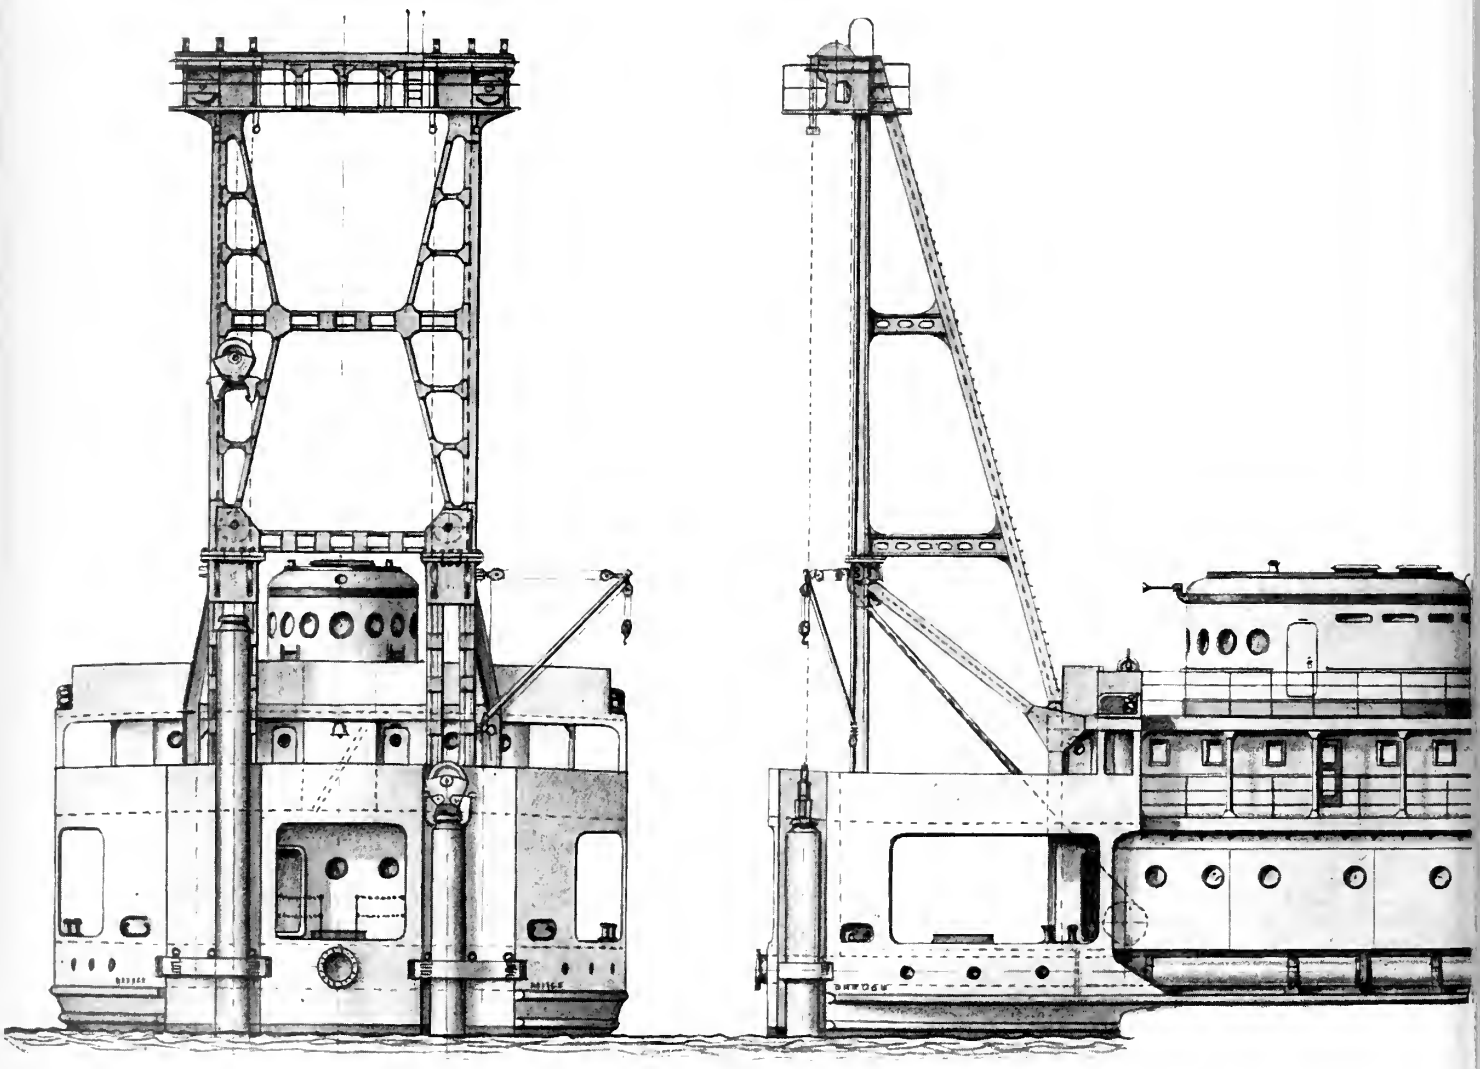
The domestic trades have never been subsidized beyond the flag protection which the founding fathers in their wisdom gave them. In general I think they should continue under that policy. There should certainly be no operating subsidy direct or indirect, and no free canal tolls. It may be that some consideration should be given to assumption by the government of a share of the costs of new construction which would encourage continuous modernization and which might well be considered a proper charge against national defense. In this same category there should be more equality of treatment between the domestic carriers and the subsidized lines in our foreign trade, with respect to Federal taxation and replacement funds.

I believe our domestic shipping is a national necessity. I believe it should be privately owned and operated under proper Federal legislation. I believe it is a vital part of our Pacific Coast economy. I am sure there will always be an intercoastal trade and so I ask of all of you your cooperation, support and sympathetic understanding to help us through the rough going that seems to lie directly ahead.

The C-4 as originally designed for the American-Hawaiian Steamship Co.



The Kinmont Ocean-going Hydraulic Dredge



The navigating bridge and pilot house on the after end of the Kinmont dredge. Pilot house occupies the aft half of the exhaust stack.

The power plants of modern hydraulic dredges and ships are similar in many respects. The main pump drive of the dredge and the propulsion drive of the ship are comparable. Of course, the dredge has two additional machinery departments utilizing power—the cutter drive and winding machinery—which are not found on a ship. These assist the main pump when the dredge is in operation. There is also a close similarity between the auxiliaries of both types of vessel.

A well-known consulting engineer, George Pelton, 10 Park Avenue, New York City, recently completed basic designs for a new-type hydraulic dredge for Kinmont Manufacturing Company of Los Angeles, California, builders of hydraulic dredges and dredging machinery, whose aim is to present to the dredging industry the "last word" in hydraulic dredges, with the most efficient type of power plant.

This seagoing dredge is provided with the Kinmont self-propelling device designed by Mr. Pelton. When preparations are made to go to sea,

this device permits the pump drive to become the propeller drive, and the dredge then becomes a ship. The various sizes of power units installed insure any desired speed up to 10 knots. The generator sets not being used for propulsion may be overhauled and made ready for the next dredging operation or held in reserve for emergency.

This 24-inch heavy duty, hydraulic dredge is suitable for all types of dredging work by hydraulic method.

Following are general specifications of this self-propelled hydraulic dredge:

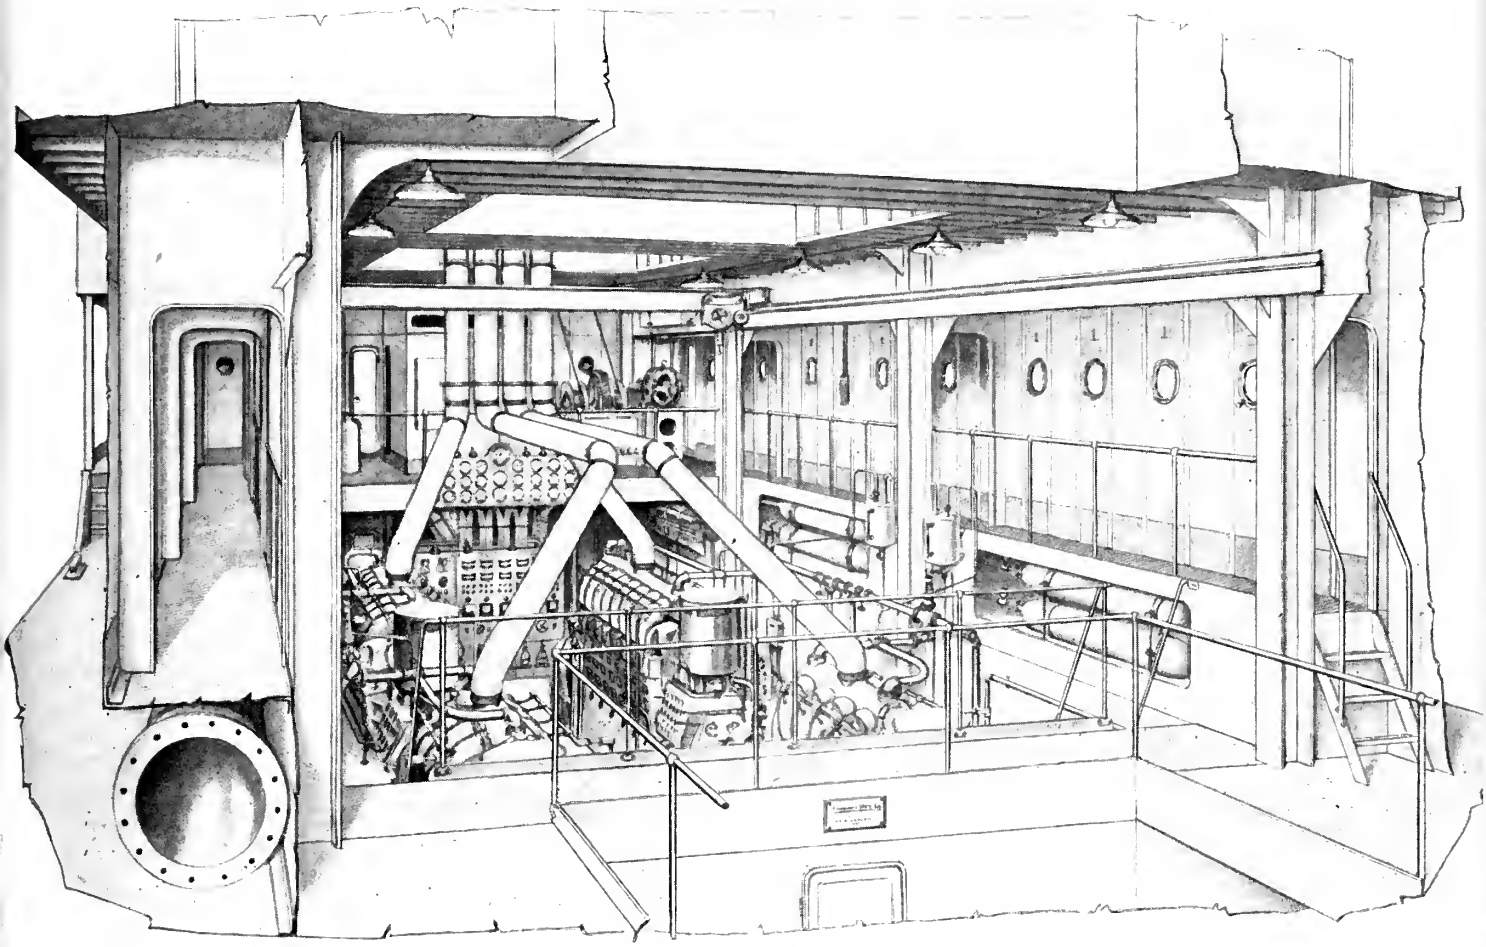
Hull Construction—The steel hull is of all welded construction. The characteristics of its design make it well adaptable and convenient for dredging operation and provide it with fine seagoing quality when the dredge is at sea. The hull is divided by two longitudinal and five cross bulkheads in several water-tight compartments. These compartments are intended for safety, particularly in the case of the Main Pump Room, where breakage of the main pump can cause the flooding and sinking of the dredge. Such accidents are well known and have resulted in the sinking of many dredges. The Main Pump Room is equipped with quick operating water-tight doors and spill pipes. Two longitudinal trusses provide the principal backbone of hull strength. They run the full length of the dredge and are in line with the longitudinal bulkheads to which they are fastened, as well as to cross bulkheads. These trusses project high above the main deck and are tied across the top in several places by means of cross-members, and are also fastened to the Main House.

This method of construction makes the hull extremely strong and eliminates the use of "Hog Frame" and "Hog Wires." However, there is a frame located at the front end of the Main House, which is similar in appearance to a hog frame, but its function is to act as a supporting frame for fastening of back guy wires of the "A"-frame, and to support the "Heavy Lift Boom," intended for handling the main pump and to serve the forward end of the dredge.

The "A"-Frame—The "A"-frame is made as a combination of two frames; the lower "Bridge Frame," and the upper "A"-frame. The lower frame is made solid with the hull, the upper rests on top of it, hinged at the bottom of each foot. This construction adds more strength to the front end of the hull, and adds extra facilities for handling parts of cutter drive and others. It also plays a part when securing the ladder for a sea trip. The upper "A"-frame becomes smaller and much simplified.

The "Spud Frame"—The "Spud Frame" is designed with a special provision which allows it to be lowered down in horizontal position for safety during the sea voyage, making the dredge more seaworthy. This is done by means of unbolting the flanges of Parting Joints of the Main Upright Members, then tilting the frame back on hinges, which are at the lower end of each back leg. It clears the smoke stack and comes to rest on the top of the upper deck when lowering it down. Lowering and raising of the

Engine room view, looking in the after direction, showing four Diesel generating sets. Note on the left the recess in the side of the house for dredge discharge pipe. Also the after hoisting units at the end of the engine room on the deck above engine room floor.



Spud Frame is done by means of a spud hoisting machinery.

The After End—The After End of the dredge rises high above the water and has "shipshape" appearance. It becomes a bow when the dredge goes to sea, for this, two large side plate doors and one end plate door are bolted in place, making the bow completely enclosed. It becomes a fine breakwater against heavy waves. The round shape of this bow cuts down resistance when traveling.

The Main House — The Main House is also made of steel. It adds more strength to the hull as it is tied to longitudinal trusses, as described above. All outside doors are watertight. Light is admitted through a number of portholes on both sides of the house and on the front end.

Living Quarters—Living Quarters are located always on the top of the Main House and arranged according to the Basic Plans, offering the best possible arrangement per number available square feet of space.

If the dredge is purchased originally without Living Quarters, same can be installed at a later date and be purchased in pre-fabricated stage made to fit existing conditions, provided the Basic Arrangement is used.

Dredge Machinery—The performance of the hydraulic dredge depends on three distinct well balanced departments of dredging machinery, which are: Pumping Machinery, Cutting Machinery and Guiding Machinery. By means of the dredge ladder all three are brought in contact with the material to be dredged at a specified depth.

Pumping Machinery—This department of dredging machinery receives and disposes of dredging material by means of hydraulic method of "pumping." For this, it consists of a specially designed dredge pump, suction and discharge pipes, and the driving mechanism, which rotates the pump impeller.

Dredge Pump (usually called the Main Pump) The features of "Kinmont Dredge Pump" are easily observed on the illustrations, yet we would like to say a few words, pointing out the principal advantages of the design. First: Well proportioned areas of the cross sections of all passages inside the shell and the impeller with easy curves, respectively, make the pump highly efficient. Second: Better pump protection against the wear by the lining method consisting of "metal to metal contact" of surfaces forming joints between the liners and the pump casing. Third: Complete elimination of all square shape (90°) corners in the passages between the pump and the impeller. The method of "metal to metal contact" of joints inside the pump, between the shell and the liners, completely eliminates clearance spaces where the wear originates, as rapidly traveling particles of mixture under pressure have the tendency to work their way in these clearance spaces. As this continues, they open up more and more and become badly worn ahead of other areas. This shortens the life of the liners, necessitating their replacement before being completely worn out. Sharp 90° corners of passages are subject to the same conditions as the clearance spaces. The wear generally starts in the sharp corners and then spreads out to other areas.

Removable Top Discharge Outlet—is another feature of the Pump Design. This allows replacement of the outlet in case it wears out before the pump casing. In cases where it is desired to do some work on building up vanes of the impeller, or hard facing surfaces of its shrouds, removal of the discharge outlet provides fine access to the impeller, and makes possible downward welding on same. The stuffing box around the impeller shaft has only one bolt with which packing gland is tightened.

Location of the Main Pump on the Dredge and Its Effect on Suction and Discharge Pipes—The main pump is located on the forward end of the dredge, as close to the forward bulkhead as is possible, allowing only enough room for servicing it. This location of the main pump reduces suction lift, which is very essential—the extra length added to the discharge pipe requires no extra power.

Driving Mechanism—Pump drive covered by this paragraph deals only with the part of a drive which does not go beyond connection to the Power Unit, which is made by a double engagement type flexible coupling. Everything beyond this point will be discussed in a separate paragraph under the heading "The Power Plant." The main pump is mounted on the steel bed plate, which also carries the spring bearing and the "Kingsbury Type" thrust bearing with corresponding shafts (pump shaft and thrust shaft). As an optional feature where constant speed motor should be used without any possibility for variable speeds, then "Kinmont Mechanical Speed Changer" can be installed. This device has the appearance of a gear box, provides the pump drive with four different speed changes, totaling 20% reduction, each step representing a 5% drop (for example, if high speed is 300 rpm, then 280, 260 and 240 rpm can be had). Change of speed is done by replacement of one shaft with gear in the Speed Changer, which is very simple and can be done in a rather short time.

Cutting Machinery — Cutting machinery consists of a digging cutter and machinery which drives it, usually called "Cutter Drive." Four different types of cutters are offered. Each is designed to dig a certain class of dredging material for which it is most suited.

These cutters are as follows:

(1) All tooth cutter for rock digging.

(2) Heavy duty blade cutter for hard materials.

(3) Light duty blade cutter for light materials.

(4) Basket blade cutter for soft materials.

The cutter is screwed on the end of the shaft, which projects over the forward end of the Dredge Ladder. This shaft is made of several sections, all connected together into one long shaft, which is supported by the Dredge Ladder. The opposite end of this shaft is connected to a "Cutter Drive" located on the after end of the ladder.

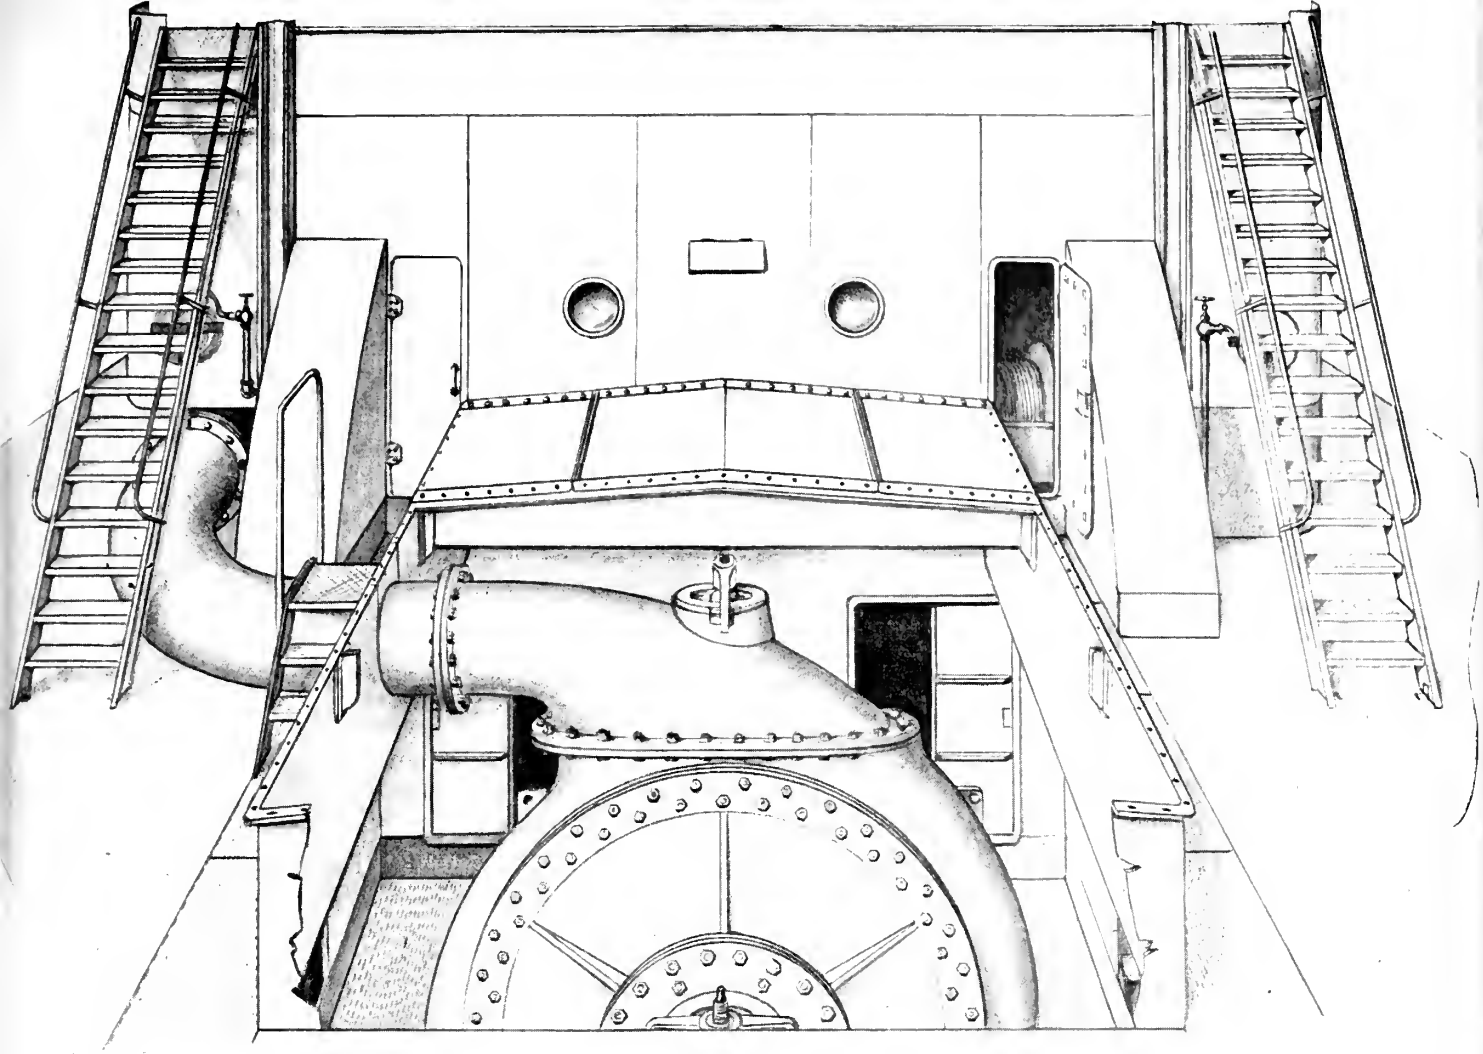
Cutter Drive—The Cutter Drive consists of two sets of reduction gears, each placed in a separate Gear Case. This arrangement has definite advantages as it permits keeping the Low Speed Gear Case out of the water, as it is located on the extreme after end of the ladder. Even when the ladder is lowered to its maximum digging position of 45°, there is no chance for the water to get into the Gear Case and mix with the oil. The High Speed Gear Case is located ahead of the Low Speed Case, but much higher, which keeps it out of the water at all times. In case one set of gears (high or low speed) has to be taken out, it is necessary to open only one set, without disturbing the other.

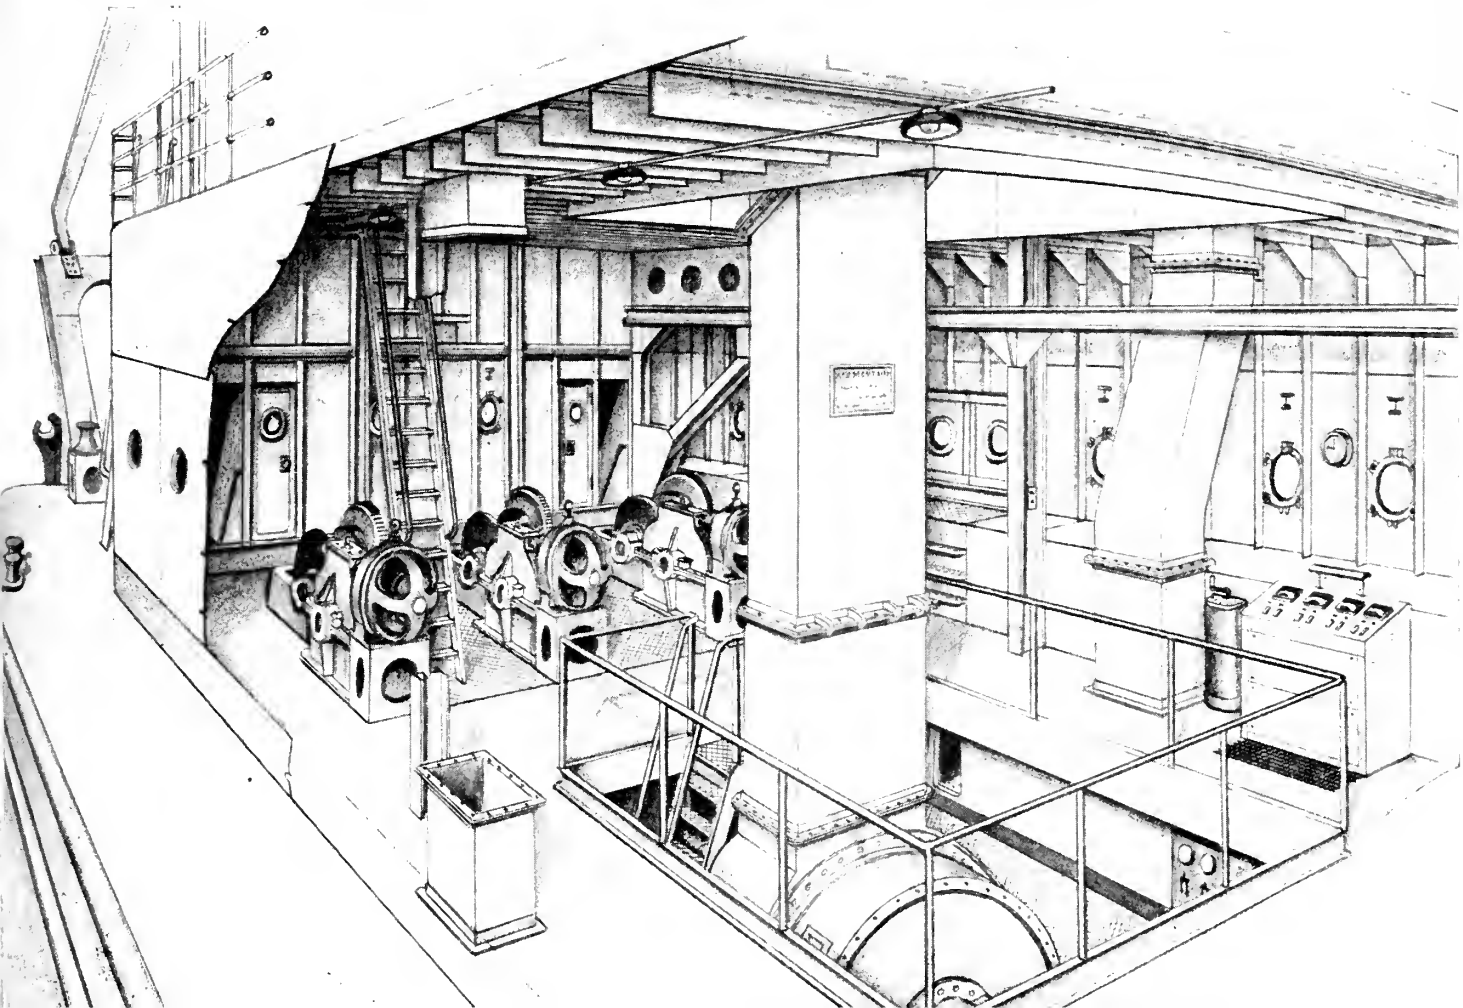
The Cutter Shaft is provided with

On the facing page:

Upper: Forward end of the dredge showing the main pumps inside the pump room with the pump hatch open. In back of the pump two quick-operating watertight doors can be seen.

Lower: The interior of forward end of main house, showing forward hoists, main pump motor and controls.





a specially designed Shear Pin Coupling, which protects the cutter machinery against breakdowns, particularly if the cutter gets jammed or receives a sudden severe shock. The Shear Ping Coupling will respond also to any other cause. The thrust which develops in the Cutter Shaft during the digging and due to the inclined position of the shaft, as the ladder goes down, is taken care of by a specially provided thrust bearing located on the after end of the ladder. The cutter drive is driven by an electric motor which is mounted on the pedestal adjacent to the back and of the High Speed Gear Case and is connected to a high speed pinion shaft by means of double engagement type flexible coupling.

The Cutter Motor should be of variable speed type if ac current is used, so that correct speed can be selected with the change of the material while dredge is digging. If dc current is used, this is accomplished much easier as dc current lends itself into variable speed by means of special controls.

Guiding Machinery—This machinery has several duties to perform:

Standard Equipment

No. 1 Duty — Swinging of the dredge from side to side.

No. 2 Duty—Raising and lowering of the dredge ladder.

No. 3 Duty—Raising and lowering of the spuds.

Extra Equipment

No. 4 Duty—Moving swinging anchors.

This machinery is commonly known as the Winding Machinery—an old-fashioned term, which cannot very well be applied to the "Modern Kinmont Machinery." In general, either one consists of several hoisting units, ordinarily five units, in special cases, seven.

The characteristics of an old-fashioned Winding Machinery are as follows: All hoisting drums generally are mounted on one foundation and are driven by one electric motor, or by any other available source of power. When the dredge is in operation (or is digging) usually there are two hoisting drums working, the other drums being held on brakes with clutches disengaged. If clutches are mounted on the side of Low Speed Gears, then all shafts and gears will be constantly in rotation. If clutches are mounted on the Intermediate Shaft, then drum shafts and gears of drums which are not at work will be at a standstill. The Intermediate Shaft will be revolving—this means that many parts rotate unnecessarily, using power and wearing out more rapidly.

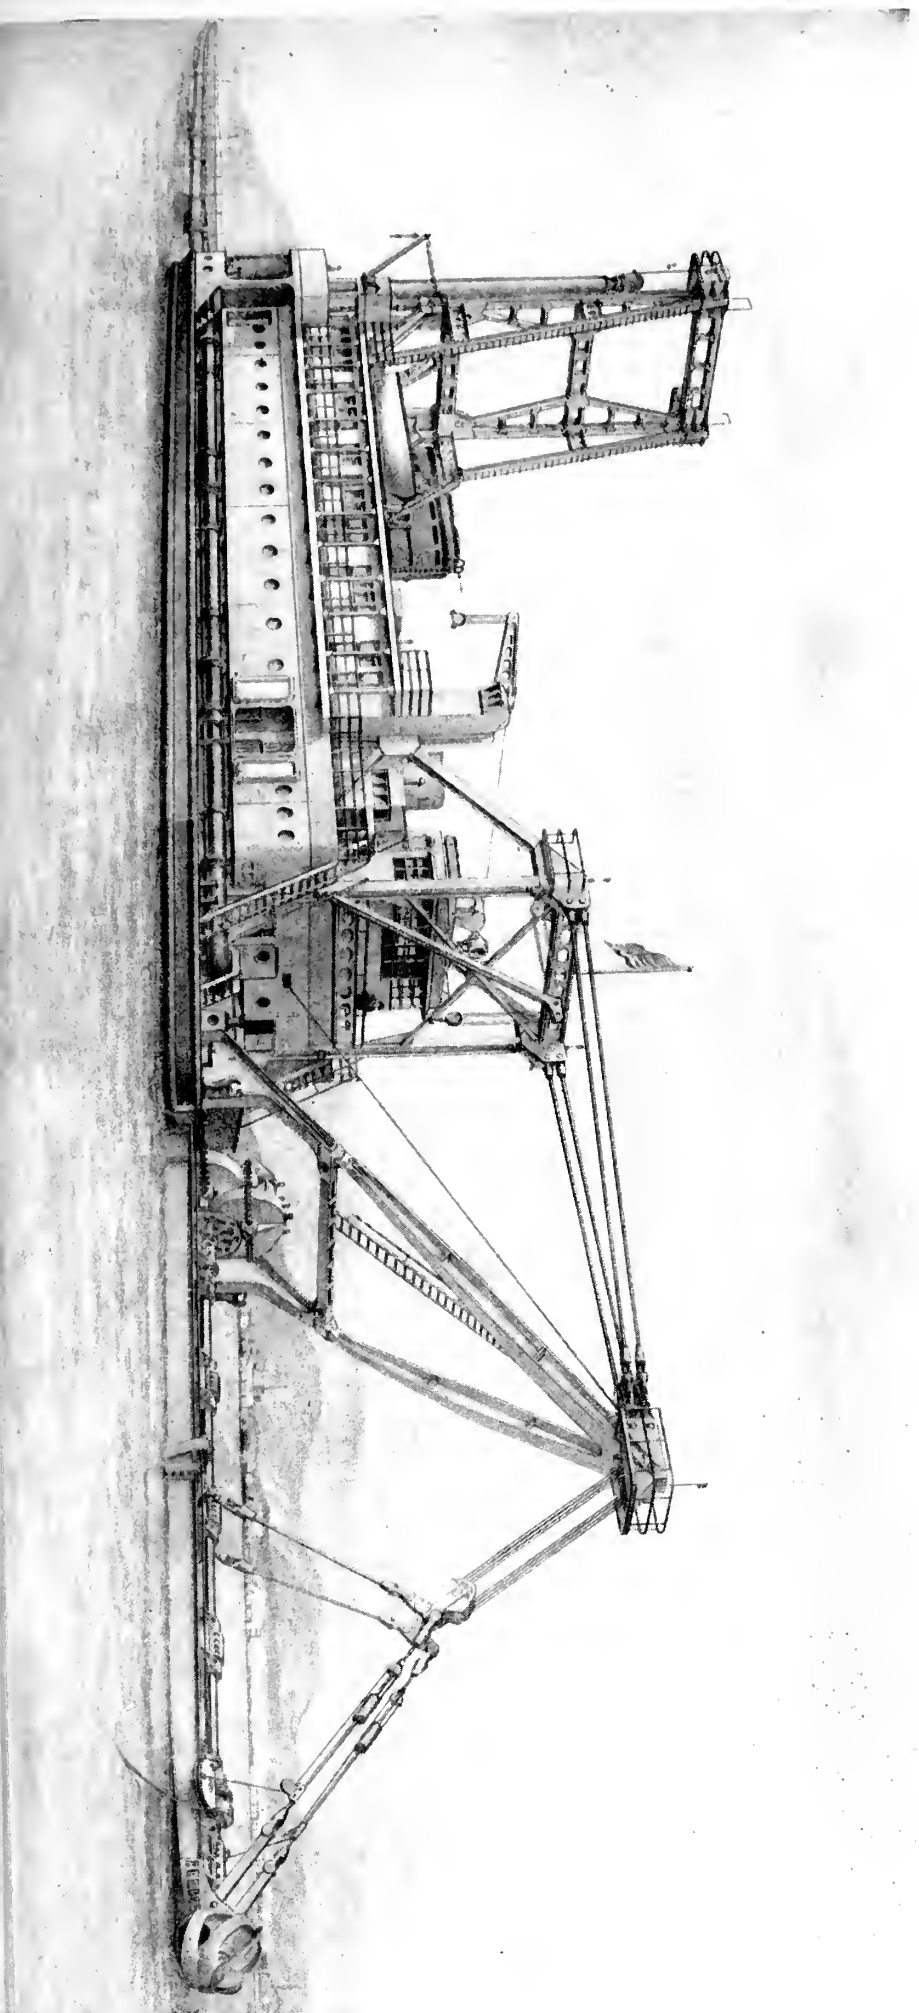
Kinmont Modern "Guiding Machinery" received this name because its function is to lead or guide the dredge when it is digging. This machinery consists of five (for Standard Equipment) or seven (for Special Equipment) individually driven hoisting units, each provided with a separate motor, arranged in groups of two: Forward Hoists and After Hoists. Forward Hoists perform No. 1 and No. 2 duties (also No. 4 in special cases), and are located inside the forward end of the Main House. After hoists performing No. 3 duty are located inside the after end of the Main House. All hoisting units are driven by individual electric motors. This system offers exceptional flexibility during the operation of the dredge, prolongs the life of the part composing hoisting units, and provides each unit with correct power and speed, which is hard to achieve in the old-fashioned types.

Forward Hoists — Two separate hoisting units similar in appearance, but driven by different size motors, are for dredge swinging. The unit which pulls the dredge during "digging swing" requires more power, with less speed, than the unit which pulls the dredge on her "return swing," as at that time no digging is done, less power but more speed is required. The third hoisting unit of a forward group performs plain hoisting duties of raising and lowering of the dredge ladder, which represents a heavy lift. It is equipped with a reversible electric motor, permitting raising and lowering of the ladder by push-button electric control — pushing upper button will raise the ladder, pushing center button will bring it to a stop, and pushing lower button will lower it. For quick lowering (or dropping) of the ladder, it is necessary to disengage the clutch, which generally is kept engaged. The clutch is also used as a brake.

After Hoists—There are two separate hoists, one for each spud, both are exactly alike, but slightly different in appearance than hoists of the forward group. These are two drum type, both drums being on the same shaft for single and double purchase duty, meaning that raising of the spud can be started on the double purchase, then by means of control changed to a single purchase. Spud can also be raised all the way up on a single or double purchase, respectively. Special spud grip allows dropping of spud without the danger of running the entire length of the wire off the drums.

Dredge Ladder—The principal duties of the dredge ladder (sometimes called "Digging Ladder") are: To reach down to a specified depth where material is to be excavated, break it up with digging cutter and pick it up by hydraulic suction. The mouthpiece of the ladder suction pipe opens inside the cutter so nothing can pass it by. This part of the ladder is called "ladder head" (the digging end of the dredge). The design proves that long experience lies back of every detail of "Kinmont Ladder Head." It has the strength, accessibility and the correct shape. It is also provided with Cutless Bearing for the ladder shaft. At a proper distance directly in the back of it, there are two special single sheave blocks for swinging wires, one on each side. These blocks are specially designed. They are fully balanced and will adjust themselves to any desired position, but will not swing, turn over or be subject to a hard drop. The digging end of the ladder is supported by ladder falls, with multiple equalizer which equalizes the pull of all holding straps. Other duties of the ladder are: To support the cutter shaft; suction pipe and the cutter drive with its motor. The ladder is the part of the dredge which gets the roughest service, so it has to be properly designed to stand the abuse. Kinmont make ladder has all the strength necessary, also the shape, which does not allow it to drag when the dredge is in shallow digging. The ladder is made in two pieces with the joint in the middle, so it can be taken apart for the sea voyage. The illustrations cover pretty well all other characteristics, including the entrance of the suction pipe into the hull. It also shows a flexible rubber sleeve. The ladder is attached to the dredge by means of hinges called trunnions, on which it hangs and pivots when lowered or raised. Trunnions of the design are made extra large to reduce the pressure per square inch of bearing surfaces, which gives longer life, more safety and strength.

Spuds and Spud Casings—In order to swing the dredge from side to side so she can dig with her cutter, it is necessary to pivot her at the after end. This is done by means of long spuds, which are put through the



spud casings attached to the after end of the dredge. Specially designed "Kinmont Twin Type" spud casings are well illustrated in this presentation. In addition to this, we want to point out that upper casings can be made with "cushioning" provision, allowing the spud casing to move in all four directions for a distance of a few inches, just enough to prevent the breakage of spud under excessive strain, which may occur at a certain interval. Kinmont Twin Type spud casings allow the change of "center" distance of spuds from smaller to a longer, depending on how much headway the dredge has to make. This is done by means of changing caps (or keepers) on spud casings from one center distance to another, and replacing spuds accordingly. The lower spud casings are made solid with the hull, and so can the upper casings. Cushion provision is an "extra" feature, and will be installed only if it is stipulated in original proposal, otherwise it will be made solid. Cushion feature can always be installed at a later date.

Power Plant — First should be pointed out all known types of power plants which can be adapted for the hydraulic dredge:

(1) All Steam
  (1-a) Part steam, part steam electric
  (1-b) Steam electric
(2) All Diesel
  (2-a) Part diesel, part diesel electric
  (2-b) Diesel electric
(3) All electric where power is received from shore.

Steam electric (#1-b) and Diesel electric (2-b) can operate as (#3) — all electric. In this article we are showing a 24" hydraulic dredge, gauging it by the size of its main pump, which is the customary way. It is claimed, from all available sources, that for all purposes of modern dredging, the Diesel electric power plant is the best type to select. There is considerable debate on this subject. A number of the dredge designers speak openly against Diesel power, instead strongly recommending Steam power, claiming that Diesel power has not proven satisfactory on various existing dredges; but it is rather doubtful that any of them can set as an example the dredge built with Ultra Modern Power Plant.

Our illustrations show this power

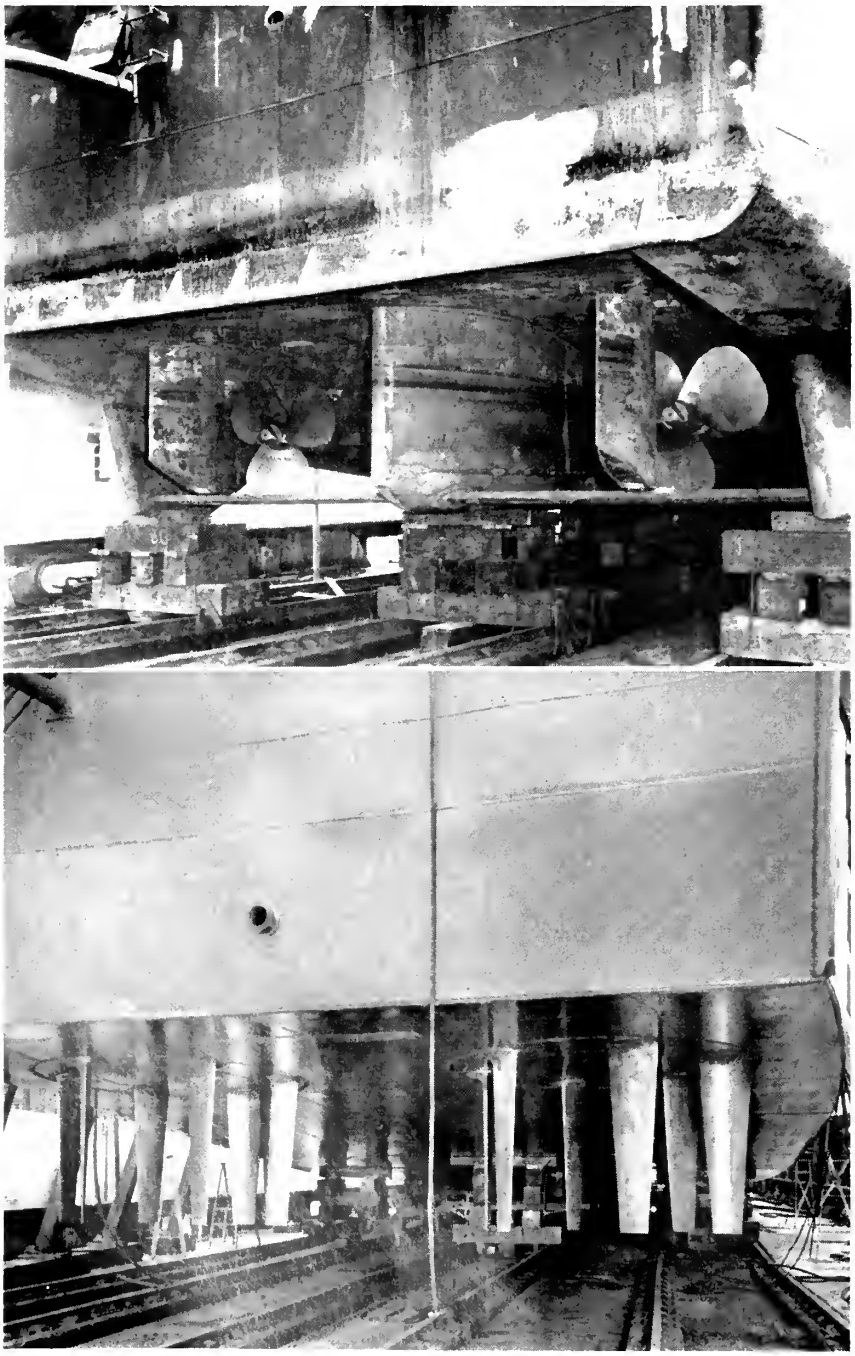
Cycloidal Propeller

U. S. Navy Tests the Kirsten System of Propulsion on West Coast

Upper: Before the hull lines of the Navy's LSM-458 were changed for cycloidal propulsion the stern of the ship had the usual propellers, rudders, skegs and struts. All these were removed and the aft part of the ship completely rebuilt before the cycloidal propellers could be installed. Lower: The complete underwater installation of cycloidal propellers on the Navy's LSM-458, looking forward from the stern, is shown in this photo. All encumbrances have been eliminated, and there is a clean, undisturbed flow along the hull bottom. Experts agree that in addition to increasing the maneuverability of vessels to an almost unbelievable degree, the cost of the cycloidal ship hull is reduced by the simpler construction.



The revolutionary cycloidal propeller, which gives ships unbelievable maneuverability, without sacrifice of speed, underwent extensive tests early in April in Puget Sound, mounted on the Navy LSM 458. Although the Navy did not reveal complete results of the tests, Navy spokesmen indicated that "almost unheard of maneuverability" is possible with this radically different propeller. Further tests are being conducted.

Invented by Professor Frederick K. Kirsten of the University of Washington, the cycloidal propeller was designed and built by Pacific Car and Foundry Company at Renton, Washington, with Kirsten as consulting engineer. The new propeller, which utilizes blades instead of the convential screw, was installed on the 900-ton LSM 458 at Everett Pacific Shipbuilding and Dry Dock Company of Everett, Washington, under the supervision of T. M. Rowlands, Chief Engineer. Pacific Car and Foundry Company hold the exclusive manufacturing license for the propeller, under the Kirsten patents.

One of the astounding maneuvers made by the LSM during the test runs was athwart-ship propulsion without ahead or astern movement of the ship. That is, the ship actually moved sideways under its own power. The vessel also was spun completely around without fore and aft movement, using its bow as a pivot.

The cycloidal propeller consists of twin propellers having an orbit diameter of seven feet, equipped with six vertical blades, each of which revolves on its own axis, as the rotors revolve. These twin rotors, circular steel housings flush with the hull, are connected to the vessel's drive shaft with a right-angle, beveled gear drive. Although the propeller somewhat resembles an egg beater, the principle is wholly different in that the revolving blades push all the water in one direction, whereas an

egg beater throws fluid in two directions.

Paul Pigott, President of Pacific Car and Foundry Company, emphasized that use of the cycloidal propeller is not restricted exclusively to Naval and military purposes. He stated that the propeller will prove of great value for such vessels as tug boats, crane barges, ferry boats, and inland and river watercraft of all types. Thor Henrikson, Chief Engineer, indicated that the use of the cycloidal propeller will result in a smoother and more streamlined hull. This is made possible by elimination of rudder gear and other appendages in screw ships. The tests indicated that the propeller materially reduces vibrations inherent in screw propulsion.

Professor Kirsten, the inventor, first conceived cycloidal propulsion in 1921 and at that time, undertook considerable research and development. Kirsten installed his new propeller on a sleek-lined 38-foot speed boat which performed many unusual maneuvers along Seattle's waterfront in the 1920's. Many tests were performed at the University of Washington wind tunnels and at the Navy Towing Basin in Washington, D. C. Scientific articles covering the amazing propeller were published in technical magazines, but in this country there was no further response to this revolutionary idea.

In Austria, however, the idea took form and the Voith-Schneider Company began to apply cycloidal propulsion to marine vessels as early as 1928. In the late fall of 1944, the United States Government became interested in this form of propulsion. Early in 1945, the U. S. Army and the U. S. Navy decided to investigate cycloidal propulsion and the U. S. Army ordered the alteration of a harbor tow boat to be equipped with cycloidal propellers of the variable pitch type. At the same time the U. S. Navy decided to try cycloidal propellers of the fixed pitch type on a landing craft of the LSM type. At the present time, the Navy ship is continuing its trials and the text is confined to this application.

The LSM-458 selected for this experiment is a vessel of 914 tons sea going displacement, 203 feet long and a 34-foot beam. It is powered by two General Motors Model 16-278A Diesel engines, generating 1800 hp at 800 shaft rpm.

The engineering work on the propeller was started in February, 1945, at Pacific Car and Foundry Company, and the two units were finished, shop tested and ready for installation in December of the same year. The propellers were installed in the ship by Everett Pacific Shipbuilding and Dry Dock Company in January, 1946, and the official trials commenced early in April.

In the yards of the Everett Pacific Shipbuilding and Dry Dock Company one of the cycloidal propellers is being lowered into position on the Navy's LSM-458. Each propeller has an orbit diameter of 7 feet, and is equipped with six vertical blades, each of which revolves on its own axis as the rotor revolves.

The propellers have an orbit diameter of 7 feet and are equipped with 6 blades each which are cast hollow of manganese bronze. The propeller rotor, which carries the blades, is driven through a unique spiral bevel gear drive invented by Professor Kirsten and built by Gleason Gear Works of Rochester, N. Y. The pinion shaft is directly connected to the engine shaft by a flexible coupling and consists of an inner pinion integral with the shaft and an outer pinion keyed to the shaft. These two pinions on the same shaft drive two spiral bevel ring gears mounted on a common spider which in turn is keyed to and drives the rotor shaft. The gear system is so designed that the pinion shaft is mounted on roller bearings and is free to float endwise. The spiral angle of the gears is cut opposite and of the proper relation to proportion the gear loads correctly and balance the pinion thrust. The gear drive might be considered the same as a herringbone gear drive but with the use of spiral bevel gears. The reduction from the engine shaft to the rotor shaft is $6\frac{1}{2}$:1.

The blade mechanism consists of a central control shaft which mounts the sun gear in the rotor and is normally stationary except when used for steering. Three idler gears mesh with the sun gear, and each idler meshes with two blade gears. As the rotor turns, the blades revolve around

View of the port cycloidal propeller looking aft from the interior of the Navy's LSM-458, after installation. The auxiliary hand wheel is for emergency steering. Steering is accomplished in the propeller by the control shaft, which, when turned by the worm and worm gear on the top, shifts the axis of symmetry of the propeller, and all blades impart their thrust in a new direction. Propeller controls are fully pneumatic, and complete vessel control is possible from the bridge. The name plate on the propeller reads: "Kirsten Cycloidal Propeller, manufactured by Pacific Car and Foundry Company, Renton, Washington."

their own axes at one-half the rotor speed; the ratio between the blade gears and the sun gear being 2:1. The blades mount vertically on their spindles and turn on their axes, while the propeller as a whole, revolves around its center shaft. This rotative motion of the blade is controlled so that each blade produces a useful thrust during practically its entire revolution on its orbit.

By virtue of its steering control, the propeller thrust may be directed any direction radially outward from the propeller shaft. Thus the ship may be rapidly reversed by turning the control through 180 degrees without altering the direction of rotation of the rotor. Consequently, the necessity of a reverse gear is eliminated, and its weight and cost are a great saving.

In accordance with Navy specifications, all bearings and gears in the propeller are force-feed lubricated. The oil is circulated through strainers, heaters and coolers by external shaft driven pumps with electrical standby units. The oil in the upper housing returns by gravity to the sump tank and the oil in the rotor is pumped out by internal gear pumps.

The double blade seals are constantly under oil pressure even when the propeller is stationary, a constant head is maintained in excess of the [illegible] water pressure to insure no [illegible] water into the propeller. The [illegible] shaft seal consists of three parts [illegible] is circulated between the two lower units for lubrication, and an oil pressure is maintained between the two upper units similar to the blade seals. Any leakage which might occur has no chance of entrance into the mechanism but may be spotted by entrance into the bilge.

The steering is accomplished in the propeller by the control shaft, which when turned by the worm and worm gear on the top, shifts the axis of symmetry of the propeller, and all blades impart their thrust in a new direction.

The propeller controls are fully pneumatic and were designed by the Westinghouse Air Brake Co. of Wilmerding, Pa. At the same time, the engine controls were converted to pneumatic and combined with the propeller controls in the same stand on the bridge. Complete vessel control is now possible from the bridge. Located in the starboard propeller room is a complete duplicate control stand for emergency operation. The necessary emergency valves and the control valve for either bridge or propeller room control are located in the engine room.

The screw propeller and the cycloidal propeller are so widely different in physical form and in their functions that no reasonable comparison can be made. The screw's single function is to produce a sternward thrust which propels the ship. The cycloidal propeller, which also produces this thrust, incorporates in addition the function of the rudder with such dynamic power that the ship may undertake maneuvers which are unthinkable and impossible with rudder control. Tests have proven that under certain conditions the efficiency of the cycloidal propeller is superior to the efficiencies obtainable with the screw.

The former screw installation included many screw auxiliaries, such as the two rudders, the ponderous skags, the stiffener strut which provides bearing support for the rudders and furthermore, the propeller hubs and shafts together with the strut supports of the stern bearings. All these appendages, projecting from the hull into the water, and which are swept by the high velocity slip stream, constitute a hull drag which exceeds 10 per cent of the total hull friction in many cases.

The use of cycloidal propellers eliminates all this encumbrance and provides a clean, undisturbed flow along the hull bottom. The higher operating efficiencies are partly explained by the cleaner and smoother hull shape. It is at once apparent that the cost of the cycloidal ship hull is reduced by the simpler construction.

It is possible to so direct the thrust that the vessel may be spun completely around without fore or aft movement. Another astounding maneuver possible only with cycloidal propellers is athwart ship propulsion without ahead or astern movement of the ship. The ship may actually be moved sideways. Thus a cycloidal vessel may be self-propelled out of close quarters without difficulty.

It is important to note that the effectiveness of a rudder depends upon its speed in the water. The lower the ship speed, the less effective is the rudder control. Thus the rudder action is poor just when it is most needed, namely when the ship approaches a landing with its speed cut to a minimum. A large ocean liner, for example, requires the help of a number of tug boats for its berthing, and for any maneuver in close quarters. The cycloidal vessel can use all of its engine power for any required maneuver, whether the ship is at a stand-still or under slow progression. No auxiliary towing craft will ever be required for a ship of any size, if equipped with cycloidal propellers.

Another source of great annoyance in screw vessels is the vibration induced by the propellers. The periodic approach and recession of the propeller blade tips toward and away from the hull creates corresponding

(Continued on Page 499)

The Reber Plan

Mr. John Reber of San Francisco has a plan and sticks to it. In that respect he is to be commended. Few individuals these days have definite plans and fewer still stick to the plans they have. Mr. Reber is not an engineer and does not claim to be. He is a promoter of his plan.

This plan is now some 25 years old. During that time several features have been added. Basically, however, the plan has one essential feature—the erection of two impervious dams across the bay by which it is proposed to turn lower San Francisco Bay, and San Pablo-Suisun Bays respectively, into fresh water lakes. All other features of the Reber Plan—the causeways across the bay, the reclamation of land for industrial and other purposes, the expansion of pier space and the assurance of fresh water conditions for the agricultural lands of the delta—are attainable to possibly better advantage without the Reber idea.

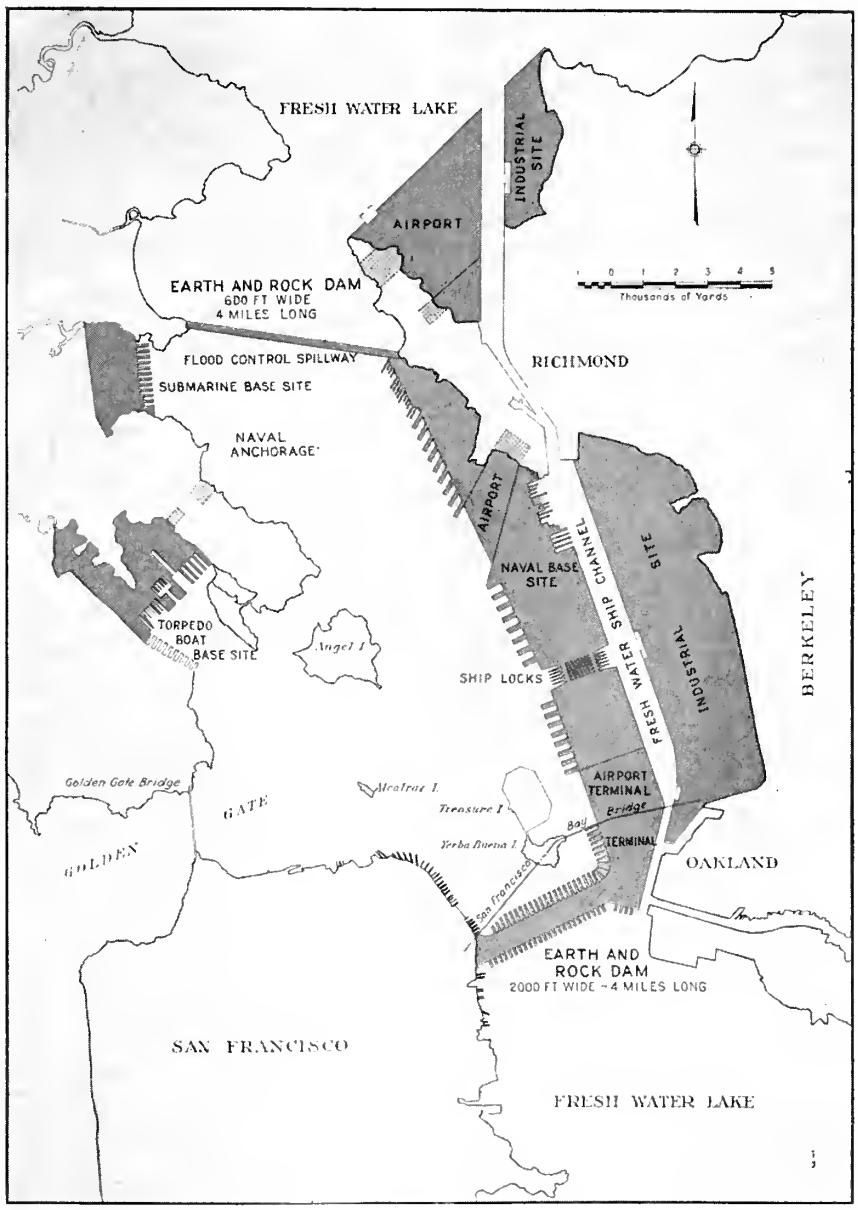
Recently this plan is again securing powerful support in the publicly acknowledged interest of Senator Sheridan Downey, of California. It was first given wide publicity during the promotion of the "Bridge the Bay" idea. At that time this plan was proposed as two causeways—one from San Francisco to Alameda, the other from Richmond Point to San Quentin Point—which would take the place of the proposed Golden Gate and Bay Bridges with much greater capacity and at much lower cost. Each of these causeways was to have locks for the passage of ships and a great advantage claimed was a tideless upper and lower bay of great area that would gradually change to fresh water.

At that time extensive experiments with models demonstrated that it was practicallly impossible to prevent salt water creeping up through the locks or to maintain in a fresh condition the body of water above such causeways. Several attempts have been made—notably at the mouth of the Nile—to preserve fresh water and create additional agricultural land in river deltas by installing salt water barriers equipped with locks, but in every instance the salt water has crept through and maintained the original status above the barrier. The new Reber Plan with its "fresh water" canal joining upper and lower lakes removes the ship locks from the barriers to a point on the canal. This, however, does not alter the fact that the salt water will go through.

Since the original proposal of this plan several large public undertakings have greatly changed some of the factors affecting the advantages claimed. The Central Valley Water Project is guaranteed to provide enough constant fresh water flow in the Sacramento to take care of the infiltration of salt water that is causing trouble in the island farms of the delta. Water conservancy measures taken by Santa Clara County have greatly reduced the annual flow of fresh water into the southern end of the Bay. This latter is affected by

(Continued on Page 450)

The criticized Reber plan.



MARITIME DAY

Bands, Floats, Exhibits Feature First Peacetime Event

By Frank Di Marco

With exactly one month remaining before the celebration of the greatest National Maritime Day (May 22) in the annals of Bay Area observances of the event, those who have been busy for the past several weeks on preparations now are able to release details of the program which will salute the Merchant Marine and allied industries in the Bay Area in a manner far surpassing anything previously undertaken.

Hugh Gallagher vice president of Matson Navigation Co., who is serving as chairman of the San Francisco Propeller Club's Committee for National Maritime Day, acted as spokesman in giving a composite report of the committee's wide-range activities. In releasing his report, Gallagher pointed out that while National Maritime Day will be officially observed on May 22, and most of the scheduled events will take place that day, activities extending through many days during May will serve to focus public attention on the Merchant Marine.

Gallagher also stressed that all groups in the maritime industry, and the entire Bay Area rather than San Francisco alone, are cooperating to make National Maritime Day here in 1946 the greatest ever and a precedent for future observances.

The opening signal for Maritime Day came on May 5th when the Pacific Inter-Club Yachting Association made a striking advance salute to the maritime industry by having their opening regatta of the season take the form of an armada of pleasure craft sailing through the Golden Gate. The armada was led by a pilot boat of the San Francisco Bar Pilots Association, which had aboard a number of maritime leaders.

From May 13th to 31st on the floor of the Marine Exchange (465 California Street) an exposition devoted to the maritime industry will be held and is expected to attract many thousands of visitors.

Open to the public without charge, the outstanding feature of the exposition will be the first public showing of a post-war passenger liner stateroom—in full size and completely furnished to afford the public the opportunity of actually inspecting the type of accommodations which will be available to those who make sea voyages on American merchant ships now that the Merchant Marine is returning to peacetime pursuits. The stateroom will be on display through joint arrangements with Joslyn & Ryan, naval architects, and Arnot & Co., metal furniture firm.

In conjunction with the stateroom will be displays of marine and nautical equipment used both in the building and operation of merchant ships. Among those firms which have arranged to show their products are Westinghouse Manufacturing Corp., Radio Marine Corporation of America, Marine Instrument Corp., and Moore Drydock Co.

On May 15th the exceedingly pop-

ular radio show, "Breakfast on Nob Hill," broadcast over Station KSFO with Bill Baldwin as master of ceremonies, will be entirely devoted to a salute to National Maritime Day. Held in the Birch Room of the Fairmont Hotel, breakfast is served at 8 a. m. and the broadcast goes on the air at 9 a.m.

Attendance at the broadcast will be limited to those having reservations. Those who do attend will have a chance to win one of several prizes, including a free trip to Honolulu for two persons or a $1000 Victory bond, a week-end for two at Sonoma Mission Inn, nylon hosiery and theater tickets.

All other events marking the observance will take place on National Maritime Day, May 22nd (Wednesday).

The first American merchant ship which enters through the Golden Gate on the morning of May 22nd will be the "honor" ship of Maritime Day in the Bay Area. The ship's captain will be the honored guest at a luncheon at the Commercial Club and the entire crew will be honored guests at a dance in the evening at the United Seamen's Service.

Shortly after 9 a.m. a solemn tribute to the great many merchant seamen who gave their lives while transporting the men and supplies needed to win the war—through never-ending perils and to every beachhead—will be held at the center of the Golden Gate Bridge. Capt. H. J. Tiedemann, Pacific District Operations Officer, U. S. Maritime Service, surrounded by an honor guard from the Merchant Marine Cadet Corps, will cast a memorial wreath from the bridge into the sea. As the wreath is carried away on the waters, every ship in the harbor will "sound off" simultaneously with a blast on its whistle. This will officially mark the commencement of National Maritime Day here.

Next event will be a mammoth parade starting from the Civic Center at 10:45 a.m., down Market Street to Montgomery, along Montgomery to California Street to pass before the reviewing stand at the Merchants Exchange Building, and thence to the Embarcadero to disband.

The parade promises to be one of the most spectacular and interesting ever held in San Francisco because it will include a large number of floats especially designed to depict every activity and phase of the maritime industry—shipbuilding, ship operation, manning, supplying, servicing and repairing. Nothing like this has ever been done before and a precedent for future observances of National Maritime Day here will be set. In addition to the floats, there will be bands, marching units, contingents from labor and fraternal organizations and others.

Companies and organizations which have pledged to enter floats are: Matson Navigation Co., American Hawaiian Steamship Co., Luckenbach Steamship Co., Moore-McCormack Lines, United States Lines, Pope & Talbot, Inc., American President Lines, Kaiser Shipyards, Moore Drydock Co., Joslyn & Ryan, Society of Mechanical Engineers, General Steamship Corp., Bethlehem Steel Co., Enterprise Engine Co., Chamber of Commerce, Mariners Club, Propeller Club, U. S. Maritime Service, San Francisco Port of Embarkation, Transportation Post of the American Legion, American Merchant Marine Library Association, and Women's Organization of the American Merchant Marine.

At 12:15 p.m. the regular National Maritime Day luncheon will be held at the Commercial Club. Attendants will be members of the Propeller Club, Mariners Club, Chamber and Junior Chamber of Commerce and other groups. They will hear a keynote speech by a national figure whose name is yet to be released.

From 3 to 5 p.m. open house will be held by the Women's Organization of the American Merchant Marine at the Davy Jones Locker Canteen, 1000 Geary Street, to tell the story of the work done by the WOAMM for merchant seamen during the war. Refreshments will be served.

The Palace Hotel will be the scene at 6:30 p.m. of the 17th annual Spring Frolic of the Mariners Club. The affair will be signalized as a tribute to the Merchant Marine and the maritime industry in the Bay Area.

A dance for merchant seamen will start at 8 p.m. at the United Seamen's Service clubroom, 439 Market Street.

All during National Maritime Day there will be specially-arranged broadcasts on all local radio stations. Films portraying the activities of the American Merchant Marine will be distributed to schools for showing to students. Posters will be placed

Top: Hugh Gallagher, general chairman of San Francisco Maritime Day Committee.

Center: Gene Hoffman, chairman of the Advisory Committee (that's the kind of a committee to get on!).

Bottom: Frank Di Marco. Between his recent shedding of a Navy lieutenant's uniform and opening his own office in the Kohl Building, Frank has found time to arrange the best observance in Maritime Day history.

Eddie Martin. Vice chairman of the Maritime Day Committee, who, in the absence of Chairman Gallagher, carried the load. (Maybe that is why Hugh has the happy look indicated on page 405.)

throughout the Bay Area and special displays will be arranged in the show windows of a large number of downtown stores and banks. Special speakers representing the maritime industry will address all local civic clubs, such as the Kiwanis, Advertising Clubs, etc., to emphasize the significance of this important event.

Capt. Claude B. Mayo, USN (Ret'd), superintendent of the California State Maritime Academy, has consented to have the training ship Golden State open for public inspection all during National Maritime Day. The training ship, recently returned from a lengthy cruise, will be berthed at Pier 16, San Francisco.

Post-war Diesel Yacht for West Coast Cruising

Wells Designed 167-Footer for Major Max Fleischmann to be Powered with Twin 900 hp. Enterprise Engines

Toward the end of the war one often heard the remark that "the days of large country estates and luxurious power yachts have gone forever," which just shows how incorrect can be the guesses of "expert" industrial forecasters. The fact is, at the end of the war less than one year old, the demand for fine yachts was greater than the supply, and many new craft are on order, although strikes are delaying production. This demand is encouraging to the shipbuilding, engineering and allied marine trades because it will provide work for a very large number of skilled men released from war jobs.

When completed early in 1947, one of the most outstanding new yachts of the year will be the 167-footer Haida now in the final stages of design on the drawing boards of John H. Wells, New York naval architect, who has been commissioned by Major Max Fleischmann to draft a steel vessel suitable for pleasure and relaxation service on the Pacific Coast.

While this yacht is to be built in an Eastern yard, namely, the Bath Iron Works, Bath, Maine, she will have Diesel propelling engines constructed by the Enterprise Engine Company, San Francisco, California.

Profile and superstructure of the Haida will be streamlined in accordance with modern ship design, but the streamlining will be carried out in a very conservative manner; in fact simplicity is the theme of her entire conception, including the interior accommodations, furnishings, decorations and fixtures. The main idea is to make her strong, seaworthy and comfortable; also capable of offshore cruises under all weather conditions. She will be air-conditioned and will have all the latest available navigating equipment, including radar, radio, fathometer, pitometer log, metal mike, and gyro compass; also CO_2 fire protection, and pilot house control of the main engines. Sufficient bunker space is being arranged to enable the vessel to cruise from U. S. West Coast ports to Alaska and return. Her decks will be of teak, and she will be classed by the American Bureau of Shipping.

Plans of the Fleischmann yacht show that she will have the following dimensions:

Length OA	167 ft. 6½ in.
Length BP	161 ft. 3 in.
Breadth	25 ft. 0 in.
Power	1,800 s.hp.
Speed	16 knots

The Haida will have twin screws, and the propeller shafts will be direct connected to two eight-cylinder, 12 in. by 15 in. supercharged four-cycle type Enterprise Diesel engines of the airless injection type. Normally these engines run at a higher speed than they will in this craft and develop 1,000 hp each; but as maximum possible ship speed is not an important factor with the Fleischmann yacht, it has been decided to adopt the best all-round revolutions and power output of 900 s.hp. at 500 rpm, and presumably little of importance is lost by this conservatism. The vessel will be equipped with specially designed three-bladed bronze propellers. As the engines are direct reversible there will be no reduction gearing, hy-

draulic clutch or electric transmission of power.

For auxiliary purposes the present plans call for two 30 kw Diesel-generator sets, but it is expected that two 40 kw units may actually be installed because of the heavy load required by the auxiliary equipment, and by the big storage batteries.

Roominess is one of the features of this attractive vessel. In the superstructure forward is the dining saloon —a room 22 ft. by 15 ft. seating eight persons. Over this accommodation is the pilot house, which will be equipped in so modern and complete a manner that the navigator may start, stop and maneuver the main engines from alongside the steering gear, and has at his command everything in the way of modern instruments to facilitate navigation.

Next to the dining saloon is a large pantry, with a companion leading down to the galley on the lower deck. Then comes the captain's quarters located on the starboard side and on the same deck as the galley and pilot house. They are complete with private toilet and bath. On the port side parallel with the skipper's cabin is a fishing-gear room and stores.

Aft again is the engine-room casing with the smoke stack above. However, the stack is really a dummy, except that it is used for carrying off the galley fumes and heating boiler outlet, as the Diesel engines exhaust under water and do not need the stack. Nevertheless, the stack space is well utilized because it houses two 8,000 cu. ft. blowers for ventilating the engine room as well as the officers' and crew's quarters.

Abaft the engine room casing on the same deck is the owner's daytime office with its own private toilet attached. Next is the main lounge, a spacious compartment 26 ft. by 16 ft. extending the full width of the superstructure. Aft again is the deck space for the owner and his guests. In the center is an escape hatch running from Major Fleischmann's sleeping quarters below, and the top of this hatch forms a table for use in fine weather.

On the lower deck, running from the stem to stern of the ship are the following accommodations: First comes the forepeak and crew's toilet with a chain locker below. The forecastle has six pipe berths.

The officers' and engineers' quarters are next in line and consist of five cabins each with two fixed berths. Their toilets and shower are forward of these cabins on the starboard side. Each cabin has wash basins with running hot and cold water. Aft of the officers' sleeping quarters is their mess room, and then comes the galley and meat chill box running the full width of the hull. The galley is equipped with a large oil-fired range, hot table and the usual cooking utensils.

Next in line is the engine room. In addition to the main and auxiliary Diesels, and the usual electrically-driven pumps, there will be installed a 23 cu. ft., 250 lb. pressure, motor-driven starting air compressor for serving the Diesel engines. The auxiliary power units are mounted on vibration dampers to ensure smooth operation. Fresh water cooling will be used for the main and auxiliary engines, a closed system being arranged in the design layout, but oil cooling will be used for the main engine pistons. For cleaning the fuel and lube oil there will be two centrifugal machines.

In order to provide absence of noise when in harbor in the daytime, and when moored or anchored at night, an unusually large storage battery group is being installed in the lazarette at the extreme after part of the hull, and this unit will be of 980 amps capacity. When power is being drawn from the storage supply, the auxiliary engines are shut down. Also in the engine room is an automatic hot-water boiler for supplying the ship's heating radiators and for heating the air-conditioning preheaters in cold weather. The steering gear is one other piece of machinery that is located in the engine room.

For total refrigeration there is a three-ton direct-expansion Freon system plant using a water condenser. A 10-ton Freon direct-expansion compressor driven by a 10 hp electric motor is used for air conditioning. There are two units—one in a hold in the forepart of the ship, and the other in the after hold. Both are automatically controlled by individual thermostats in the cabins and saloons. All owner's and guests' staterooms are air conditioned as are the dining saloon and lounge. The ventilating system is supplied by the two blowers in the stack and fresh air is piped through ducts in the engine room to various locations. This blower system is piped to the officers' and crew's quarters and to the galley, and is equipped with preheaters.

Aft of the engine room, separated by an insulated and water tight bulkhead, are two guests' staterooms, the larger having twin beds while the other has a single bed. One bathroom on the portside abaft of the single cabin serves both compartments.

An insulated and watertight bulkhead separates the guests' quarters from Mrs. Fleischmann's accommodation. The latter consists of a tastefully furnished stateroom on the starboard side, directly connected to a dressing room on the portside and to a private bathroom. Her cabin has a three-quarters bed. Next comes Major Fleischmann's stateroom, which is fitted with a large berth and settee, and has a private toilet and shower.

On top of the ship's superstructure are located the yacht's launches, dinghys, life rafts and a canoe. The owner's launch is of the cabin type, 26 ft. by 8 ft. She has a cabin with two bunks and toilet; is equipped with a 120 hp gasoline motor, and has a fish box, chair, etc., in the cockpit aft. To make her a lifeboat, the hull has air tanks fitted into the sides.

The crew's launch also is of the cabin type, 24 ft. by 7 ft., and is driven by a 100 hp gasoline motor. She has a small toilet under a seat forward, and is provided with a fish box.

When completed and commissioned Major Fleischmann new craft will make a worthy addition to America's marine pleasure fleet. Her appearance in Pacific Coast waters will be awaited with much interest.

Following is listed some of the equipment which will be installed on the Fleichmann yacht:

Designer	John H. Wells, Inc.
Builder	Bath Iron Works
Main Diesels	Enterprise
Auxiliary Diesels	U. S. Motor
Storage Batteries	Exide
Gyro compass	Sperry
Automatic steering	Sperry metal mike
Steering gear	Sperry
Air conditioning system	Young Radiator
Davits	Welin
Heating boiler	Way Wolff
Propellers	Hyde
Insulation	Possibly Fiberglas
Fire extinguishing system	Kidde
Underwater exhaust	McLachlan
Oil burning range	Shipmate
Cabin decoration	Vogel
Joinery	Hopeman Bros.
Fathometer	Submarine Signal
Radar	Raytheon or Sperry
Fuel and Lube oil centrifuges	Sharples
Tube log	Pitometer

Dehumidification and the U. S. Navy "Inactive Fleets"

By Capt. T. H. Urdahl, USNR
and
Comdr. E. R. Queer, USNR

With the end of World War II preservation measures to implement the U. S. Navy's "Keep the Fleet" program are not only well defined but are already being applied. At the end of World War I the same factors which make up the problems of preservation were as well known as they are today but the "engineering link" between desirability and practicability had not been forged. The preservation methods employed were made by the application of materials readily at hand. Such ineffective and costly methods have served as ample reminder of the necessity for a more adequate means of protecting our Naval vessels against the ravages which nature holds in the form of atmospheric corrosion. Today, approximately 2700 ships of combatant and non-combatant types are being protected by employing scientific means of dehumidification, painting, thin film rust preventive compound application, and tight packaging. The speed at which the ship so preserved can be returned to an active status has been a primary consideration in the selection of preservation methods. Through these procedures, both quick and inexpensive, it is certain that our Navy will remain in an excellent condition of readiness for many years.

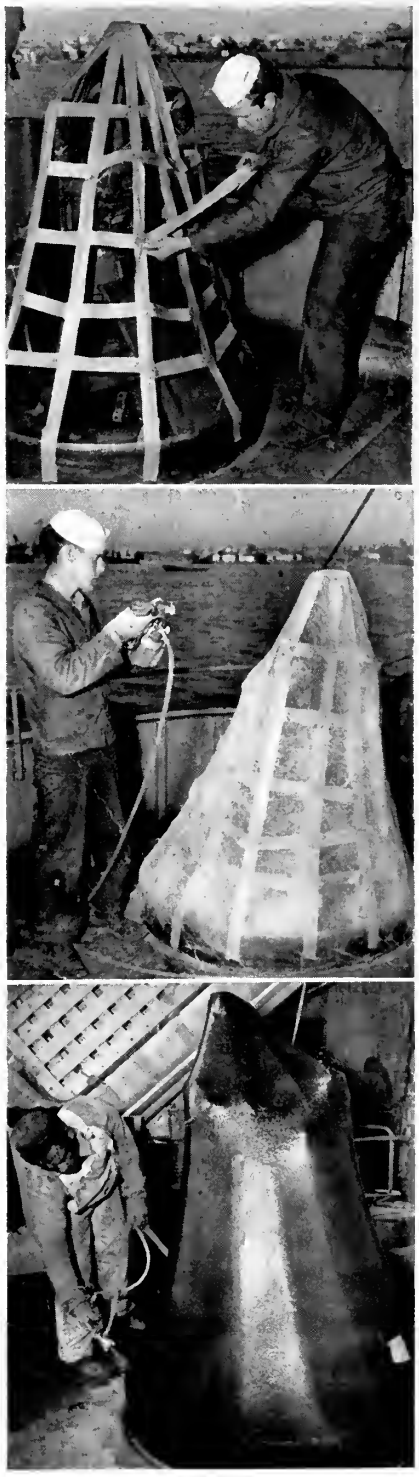
The problem presented in the preservation of a ship contains the following rather elementary factors:

1. Moisture and atmospheric conditions cause corrosion of metals, mold, mildew and general deterioration of equipment and materials aboard.
2. The removal of equipment and materials for storage ashore is expensive and storage offers no protection against deterioration unless adequately treated.
3. Adequately closing a ship's hull provides an excellent vapor and water barrier and quantities of atmospheric moisture admitted by breathing and infiltration can thus be controlled.
4. Preservation by means of coatings alone is not sufficient.

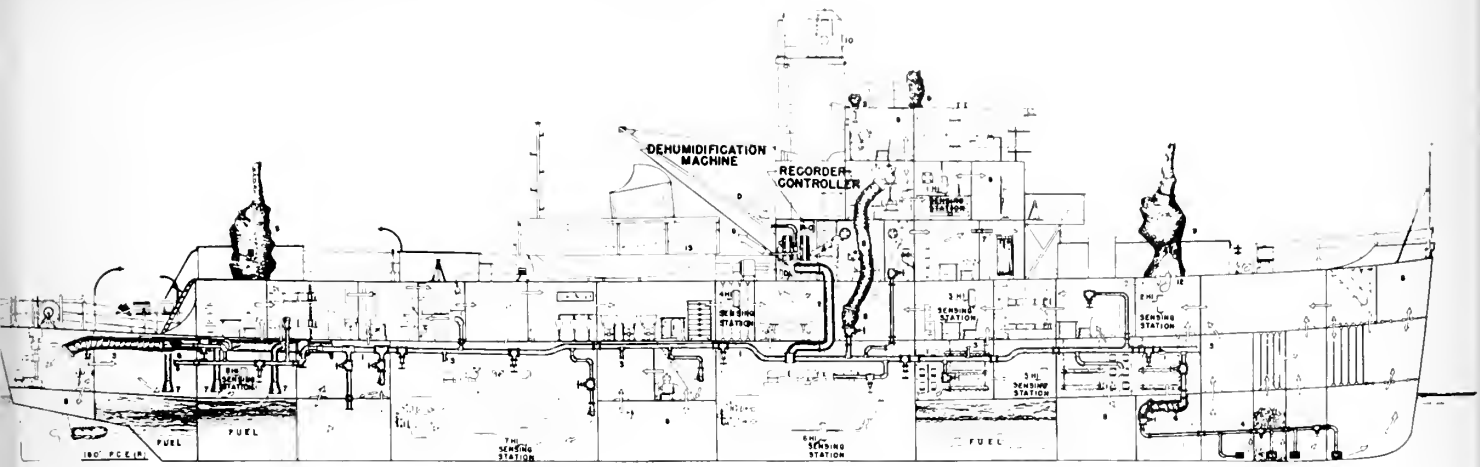
The solution most immediately apparent in analyzing these factors is that of using the ship as a storehouse for all of its own required equipment. The ship must be as tight as economically practicable against the admission of outside air and moisture. The atmosphere within should then be sustained at a relative humidity of 30 per cent or less, since at this point it has been determined that general deterioration is inhibited for an indefinite period. The practicability of obtaining this solution was dependent upon development and manufacture of equipment which could maintain the desired low humidity condition under the entire range of weather conditions prevailing throughout the year in any of the fourteen berthing areas variously dispersed about the continental United States. Also basic to the matter of obtaining adequate equipment was quantitative data concerning moisture loads to be removed in order to arrive at economical unit sizes to cover the space requirements of various types of vessels.

A great deal of thought concerning this and similar preservation problems has taken place over the past 20 years. Some development work had been carried on toward providing equipment of a satisfactory type to accompany the desired control of humidity just prior to World War II at which time the Navy's development efforts were diverted to the essentially higher priority of active fleet equipment.

However, the past work had form-



The first step in readying the guns is to see that they are thoroughly cleaned and free from rust. All protruding parts are then covered with felt and a "tent" is made over the gun with a type of adhesive tape. After the tape has been applied the webbing agent is sprayed on. This agent is a liquid when it is put into the tube of the spray gun. It is invisible when it leaves the gun and forms the web upon contact with the air. The next stage is the applying of what is called stripable coating. This is applied in three layers, yellow, red and blue. During these applications, two holes are left in the cover, one on each side of the gun. Through these holes heat is applied and the paint thoroughly dried out. After the moisture is removed, one hole is patched. Into the larger hole is inserted a lucite window. Silica is placed inside the packaging and it is closely watched for a color change. Silica absorbs moisture from the air and keeps the gun dry. When the silica has changed from white to blue in color, it is no longer any use and has to be changed.



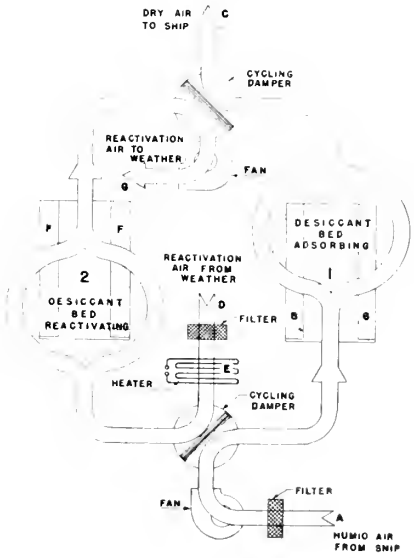
ed a basis for recent development for future requirements. The dehumidification of vessels for cargo preservation had been successfully accomplished by one company, who pioneered the idea. All of this background including that with cargo vessels contributed in pointing out the many difficulties and variables that such a problem involved, and by no means least, showed the necessity for the development of more practical and efficient equipment.

The present program and the equipment which is basic to its success was begun, evolved, and completed in the last two years, with the assistance and advice of many manufacturers, and consultants whose various contributions were carefully screened, considered and finally molded by the Bureau of Ships into a composite idea upon which the Navy was able to proceed. Test installations were made in various localities on various types of inactive vessels for the purpose of determining the practicability of these preservation measures. Dehumidifying machines were designed, tested and redesigned toward obtaining the desired efficiency and ruggedness of construction toward long life with a minimum of attention.

The results have produced dehumidifying machines employing solid chemical desiccants and a method of control of these machines combining the features of averaging, recording and indicating. In addition to these, other means of moisture removal with static desiccants, methods of packaging deck equipment and ordnance and under certain conditions the application of preservatives on bright steel surfaces. With the equipment now being installed the ship virtually becomes a dry storage warehouse and the necessity for additional storage ashore is eliminated.

The Ship. Upon receipt of orders to the Inactive Fleet, the ship proceeds immediately with preservation measures. Upon reporting, all urgent repairs will be accomplished and the ship will be dry docked to apply new anti-fouling paint and to have other essential underwater work undertaken. There is an immediate one-third reduction of the war time complement by detaching the special radar, communications and gunnery ratings.

Preliminary preservation measures, consisting of cleaning and drying the ship's hull and machinery, will be accomplished and thin film rust preventive compounds applied. The equipment is ready for immediate use without the removal of preservatives. Although there are very few vermin, germs and insects on naval vessels, prior to final closure, the ship is completely fumigated. During these initial preparations the dehumidification equipment is installed according to plan and made ready to operate. The last stage before the ship goes under dehumidification is to seal the envelope from the sea and the weather and to open doors and hatches as needed for the dry air flow. However, the watertight integrity of the ship is maintained at all times. Although it is desirable to make the topside as tight as practicable, it is not essential that the ship be made pressure tight to secure good economy of operation; watertightness however is absolutely imperative but easy of attainment.



Dehumidification is accomplished both dynamically and statically:

(a) Dynamic dehumidification consists of forcing the ship's air through an automatically controlled and reactivated chemical desiccant machine connected to a distribution system. The fire mains will be drained and since they extend throughout the ship they provide an excellent means for distributing the small quantities of dry air and return flow is controlled by choice of closure of access openings. Figure 1 shows a typical system. Fire protection is provided from the shore and fire boats. The distribution does not have to be positive to all spaces. It has been determined by test that diffusion will provide satisfactory distribution for inner bottoms, appending tanks and voids.

(b) Static dehumidification is obtained by placing metal containers of desiccants in closed voids, tanks and metal packages. This system is used only in spaces that cannot be easily reached dynamically or where the watertight integrity of the ship would be violated through opening doors,

hatches and manholes. Only about five per cent of the overall Inactive Fleet dehumidification will be accomplished statically.

The process of dehumidification is divided into two stages, namely: initial drying and maintenance drying. During the initial drying period all free water is removed from the bilges; steam, water and drainage piping; boilers and machinery. Portable dynamic machines are used to predry. After the pre-drying is accomplished and the main dynamic system

Rear Admiral Thomas B. Richey, USN, retired, has been appointed assistant vice president of Cargocaire Engineering Corporation, New York City.

put into operation, the moisture load is composed of air entrained vapor and a considerable quantity of water vapor adsorbed in the painted surfaces, lines, mattresses, etc. In initial drying the machines will operate continuously for four to six weeks drawing the absorbed water from the surfaces while the space humidity is reduced to 30 per cent. During the maintenance drying stage the moisture load is reduced to chiefly breathing caused by diurnal changes of temperature, infiltration and such topside and underwater leakage that may inadvertently occur. Such leaks must be found early and caulked, otherwise the dehumidification machine becomes a costly bilge pump. For the most economical use of the equipment the machine capacity should be installed to take care of that amount of ship's space to provide 12 hours of operation during the maintenance stage. Since breathing is the major load the machines operate principally at night and the early morning hours. The relative humidity decreases during the day because of rising temperature, whereas it rises at night because of falling temperature and breathing of weather air.

THE EQUIPMENT

Dynamic Dehumidifiers. The dynamic machines used for the Navy Inactive Fleet are the dual bed type. The desiccants employed are silica gel and activated alumina. The general arrangements of the machine circuits are shown in Figure 2. Humid air is drawn from the ship and passed through the absorbing desiccant bed. A high pressure fan returns the air to the ship through distribution system. A second air circuit is provided for the reactivation of the exhausted desiccant. In this, weather air is heated with electrical elements located either directly in the desiccant or by strip heaters in the air stream. The effluent reactivation air is discharged overboard to the weather. The control of the cycles is accomplished automatically with a timer or by a thermostat.

Most of the requirements will be taken care of with three standard sizes of machines. A summary of the specifications for the dehumidifier units is as follows:

Package Dehumidifier. The Package Dehumidifier is a single bed type developed for drying metal packages over mount guns and searchlights. It is also available for isolated compartments to which it is uneconomical to extend the dynamic system from a ship zone. The unit is also capable of handling small vessels such as landing craft. The cycle on this unit is automatic consisting of two hours and twenty-five minutes adsorption, and thirty-five minutes reactivation. The Package Dehumidifier with the proper reactivation air connections to the weather can be substituted for the Portable Dehumidifier mentioned hereafter.

Portable Dehumidifier. The Portable Dehumidifiers are used for initial drying of compartments, fresh water tanks, piping, boilers, etc. They have been found useful for initial drying of spaces that are to be treated statically and before and after painting. The unit consists of a container called a Desicannister filled with forty pounds of silica gel. To this is attached a fan with a heater unit. Air from the compartment to be dried is circulated through the Desicannister. In drying piping, the ship or weather air is predried and forced through the pipes. When the desiccant is exhausted three indicator gel ports show a pink color. The Desicannister is reactivated by removing the unit from the compartment to an undried portion of the ship or to the weather and using the built-in elec-

	Package	Small Size	Large Size

70° F. 35% Humidity	0.85	1.00	1.00
40° F. 35% Humidity	1.40	.....	1.25

* Lb. per day.

trical element to heat the air passing through the desiccant, until the indicator ports again show blue. Each unit is supplied with two Desicannisters.

Desicans. The Static Dehumidification is accomplished by placing approximately 5½ lbs. of silica gel in a permanent aluminum container with perforated surfaces. Each container is provided with a port containing indicator silica gel. These units are called Desicans and come packed eight or nine in a metal drum carrying case.

Breathers. Fuel tanks will contain oil or be coated with oil as a means of protection. Diurnal changes in temperature will cause breathing and to prevent an accumulation of condensed atmospheric moisture in the tanks, breathers are provided on the weather vents. The breather for fuel tanks contains an inexpensive desiccant that can be discarded. Desiccants will adsorb oil vapors which in addition to producing a hazard during reactivation will carbonize and damage the desiccant. Breathers may also be used on metal packages under static dehumidification. Some thought is being given to the development of a solar reactivated Breather.

Reactivator. An automatic temperature controlled electric oven is provided to reactivate the Desicans and those Breathers which may be used on metal packaging. The air is heated to 325° F. and circulated with a fan.

Controller-Recorder. The relative humidity in the dynamic zones will be controlled and recorded by a Controller-Recorder of unique design. This instrument is a combined development between the Bureau of Ships, Air Conditioning Section and an instrument manufacturer. The instrument consists of a main control and recording station to which are connected eight stations for sensing the relative humidity. In addition each sensing station contains a temperature element. A record of the temperature and humidity is printed in arabic numbers on an adding machine strip paper once every fifteen minutes continuously or once every 12 hours as desired. The identifying station number and the time are also printed.

For control purposes the instrument continuously averages the relative humidity at the eight sensing stations. If the average ship's relative humidity rises above, say 35 per cent, the dehumidifier will be turned on and continue to operate until the average is worked down to, say 27 per cent. The differential is adjustable so as to prevent short cycling of the dehumidifier. The Controller-Recorder will assist in balancing the distribution of dry air in the ship. If the humidity at a particular station is running above 35 per cent R.H., the air control valve (a fire main valve) in that subdivision of the ship is opened to allow an additional amount of dry air into that subdivision. Conversely, if another subdivision is below 25 per cent R.H., then the control valve for that section can be adjusted accordingly. With the aid of a simple direct reading air flow meter developed by the Bureau of Ships, these adjustments can be made by an enlisted man serving on watch. In the event of persistently high values of humidity an inspection must be made to determine the source of

(Continued on Page 456)

Oliver D. Colvin, naval architect and inventor of the Cargocaire system of dynamic control of humidity and ventilation for cargo ships, and Capt. Thomas F. Urdahl, U. S. Navy Bureau of Ships. Capt. Urdahl facetiously dubs the Navy's long-range preservation plan for laying up more than two thousand of Uncle Sam's best fighting ships "Operation Mothball." They inspect the skeleton display unit of the Cargocaire dehumidifier used in the plan as seen at the recent New York Chemical Show.

The scientific control of ship sweat and cargo sweat by dynamic dehumidificotion and controlled ventilation was perfected in 1936 by Colvin and has been successfully used by major U. S. shipping lines for the past eight years.

The Bendix Recorder-Controller, Model 725, a device which automatically controls the dehumidification machinery used to dry the holds of cargo vessels, is now available. Originally designed for humidity control of the sealed interior of inactive and reserve Navy vessels, it is applicable to the old or new air conditioning installations in merchant ships. The new Recorder-Controller consists of eight identical Measuring Units and a Central Station. The Measuring Units are dispersed throughout the hold or enclosure served by air conditioning machinery. Each unit is assigned a station number so that the recording made at the Recorder-Controller Central Station can be associated with that particular unit. Each Measuring Unit reports the temperature and humidity of its particular location to the Central Station through electrical connections between them.

Steam Turbine Drives

By M. Weitzner

At the meeting of the Northern California Section of the Society of Naval Architects and Marine Engineers, San Francisco, May 30th, the program consisted of a symposium on "Various Types of Main Propulsion Drive for Ships." Morris Weitzner of the Shipbuilding Division of Bethelehem Steel Company handled the Steam Turbine Drive, Charles G. Cox of the Nordberg Manufacturing Company spoke on the diesel drive, and G. L. Crow of the General Electric Company treated the diesel electric drive.

We present herewith a full abstract of the paper by Mr. Weitzner to be followed in the June issue with a complete report on the other two papers and on the discussion.

A symposium of this nature brings out all the important types of difference between the various types of marine machinery and is of great value to shipowners and ship builders.

Morris Weitzner, Chief Engineer of Bethlehem, San Francisco.

In the selection of the type of main propulsion and auxiliary machinery for a vessel the principal factors to be considered are reliability, fuel economy, space, weight, cost, and suitability for the service intended. The reciprocating steam engine, the geared steam turbine, the turbo-electric drive, the diesel straight geared and electric drives combine the above factors in various degrees. Each type has a field of application where it fits in well. These fields of application overlap. It is this overlap, which introduces considerable controversy in the selection of a unit for specific application. Arbitrary selection should be avoided, for it may result in an expensive proposition to the owners and a headache for the operators. Suitable choice can be arrived at only by consideration of all pertinent factors involved in each application. With the above in mind, I propose to discuss the merits of the geared steam turbine plant for marine propulsion.

Modern geared steam turbine installations have a very high degree of reliability, as a result of development over many years in service. Trials in service over long periods plus various theoretical studies and experiments and experience gained from land units were applied to marine service with good results. As pressures and temperatures were increased, designs and materials were provided to suit.

Experience prior to World War II was uniformly good, based on reports from owners and operators having experience with this type of equipment. This result was obtained with experienced personnel and under conditions which permitted repair whenever necessary. During World War II, there were a number of failures principally due to war conditions, such as: lack of maintenance, deferring of repairs, and inexperienced personnel. In spite of these conditions, this type of plant performed well, and today, the marine geared steam turbine plant occupies a very favorable position in the marine propulsion field with respect to reliability.

Fuel Economy

In general, for merchant vessels, the fuel consumed per SHP per hour for all purposes ranges from .61 pounds for a 4000 SHP installation operating with steam condition of 425#G and 740°F at the throttle, down to .51 pounds obtained recently on a 10,000 SHP installation operating with steam condition of 1400#G and 740°F at the throttle plus two stages of reheat to 565°F. For Naval vessels the fuel rates are somewhat higher.

This high level of fuel economy has been achieved partly by improvements in efficiency of the various units, but principally by adoption of higher steam pressures and temperatures.

Modern geared steam turbine plants operate with steam condition of 425#G and 740°F total temperature at the throttle. There are a few merchant vessels operating with 500#G and 850°F. One merchant vessel is operating with steam condition 1200#G and 740°F at the throttle plus reheat to 740°F, and another vessel is operating with 1400#G and 740° at the throttle plus reheat to 565°F. The Navy has adopted 600#G and 850°F total temperature as standard for its more important vessels.*

These pressures and temperatures were made possible by many improvements in the art of building machinery. Welding, for example, contributed greatly toward the construction of high pressure vessels. The application of welding to steel castings resulted in sounder structures for turbine casings and gear housings. "X"-ray and gamma-ray inspection made it possible to determine whether the welds and steel castings were sound. Alloy steels were developed which can withstand the temperatures involved.

The efficiency of the marine reduc-

*The author is confining his figures to American Merchant Marine.

tion gear has been raised to 98% or better, depending on type and size of unit. The drop in efficiency is about 1½% over the range from full power to 25% of power.

The efficiency of the marine propulsion turbine was raised considerably, through the use of double reduction gears and more efficient steam path through the turbines. Double reduction gears gave higher rotation speeds, short stiff turbine rotors and more efficient blade heights. This combined with better shaped nozzles and blades, reduced windage losses, and draining away of condensate in the wet regions, produced efficiencies of 75% or better in units of 4000 to 8500 SHP operating with steam condition of 425#G and 740°F at the throttle, and a back press of 1½" Hg absolute.

Important was the rise in efficiency of the modern water tube boiler, by the addition of economizers and air heaters, to 86% or better maintained in service by average experienced operators.

G. L. Crow of General Electric, whose paper on Diesel Electric Drive will appear in the June Pacific Marine Review.

Low and high pressure feed heaters using steam bled from the turbine may reduce fuel consumption by 2% for each heater.

Driving the auxiliaries with electric motors gives a gain of the order of 3% and in some cases more.

Comparing the modern 425#G and 740°F installation with one operating at 265#G and 75° superheat, which was standard about twenty years ago, the estimated reduction is about 13% for steam conditions alone.

Adopting 600#G and 840°F for a 6000 SHP installation gives a reduction of about 6% from a 425#G installation.

Comparisons of the fuel economy of various propulsion drives involves other considerations than just fuel rates. Various types of drives affect weight of machinery and space required for carrying fuel. A fairer basis would be ton miles of cargo (deadweight) carried per ton of fuel at required speed. Vessels seldom run at exactly the same speed and therefore some simpler basis is in order.

A modification of the conventional fuel coefficient, from

$$\frac{\text{displacement } 2/3 \times \text{speed}^{\,3}}{\text{Tons fuel per 24 hours}}$$

to

$$\frac{\text{cargo deadweight } 2/3 \times \text{speed}^{\,3}}{\text{tons fuel per 24 hours}}$$

For an owner this would be a better gauge of fuel performance than fuel rates. In this connection it is hoped that operators and owners will volunteer the necessary data in the inter-

Charles G. Cox, Nordberg Manufacturing Co., whose paper on the Diesel Drive will appear in the June Pacific Marine Review.

est of furthering the art of shipbuilding and ship-operation.

Table I gives trial data on fuel consumption for various well-known American steamers with varying steam conditions on geared steam turbine drives.

Space

Space devoted to machinery is governed by the requirements of the tonnage rules. That this space must be at least 13% of the gross tonnage if the 32% deduction for figuring the net tonnage is to be allowed. Compliance with these rules results in an allotment of space adequate for making a satisfactory geared turbine installation.

Due to the limited space available on naval vessels geared turbines of large power fit in very well. Table II gives an idea of the cubic requirements for various installations.

Weight

The earning capacity of a vessel is affected adversely by excess weight. The weight of a machinery plant should be as low as possible consistent with the requirements for ruggedness and reliability. The modern geared steam turbine plant is in a favorable position with respect to this item, because of its high shaft horse power output per ton weight. Table III contains data showing the power output per ton weight for several installations.

In comparing various vessels, the total weight of the main and auxiliary machinery should be included. Remember that each class of ship includes special service equipment which other classes of vessels do not require.

Cost

Based on information obtained prior to World War II, geared steam turbine plants cost 5 to 15% less than other types of drives for a given vessel. World War II may have changed this condition by standardization and quantity production methods. It is difficult to state just what the present relative costs are.

In comparing fuel consumptions it is important to compare total costs of fuel and for operating costs to include such items as cost of lubricating oil, maintenance, and repairs. Based on information gathered informally, these operating costs for the geared steam turbine plant are low compared to other drives of equal power.

Suitability for the Service

The geared steam turbine plant has given good service in many freighters, tankers, passenger vessels, passenger and cargo vessels, on carriers and many Naval vessels. The applicable power range is from 3000 SHP to about 40000 SHP per shaft. It has satisfactory maneuvering and backing qualities. For the usual weight and space allowed for fuel in the design of a merchant vessel, it has a satisfactory cruising radius.

These many installations have proven in service that the geared steam turbine is a thoroughly reliable unit for marine propulsion and that it has good all around economic performance characteristics. Further, as service experience is obtained with the higher pressures and temperatures, there is promise of better economy for future installations.

TURBO-ELECTRIC DRIVE

There were quite a number of installations with this drive prior to World War II and their record for reliability is good. During World War II, due to inexperienced personnel and other wartime conditions, a number of failures were experienced with this drive as well as with other types of drives. However, it must be said that in spite of all these conditions, the record of the turbo-electric drive established during World War II is good. The failures were relatively few and were not chargeable to this particular type of drive.

Fuel Economy

The over-all fuel economy of this plant is not as good by about 5% as that of the geared steam turbine plant for the same operating conditions.

Space

As stated under the geared steam turbine plant, the space normally allocated in merchant vessels is adequate for the installation of the usual types of drives. However, because this type of drive does not require long lengths of shafting, motor and generators may be placed wherever the space conditions permit best. This often leads to a better utilization of the space. This is quite a desirable feature in those vessels where the machinery is midship and the propulsion motor is located way aft.

Weight

In comparison to the geared steam steam turbine plant, the turbo-electric drive is usually heavier. On installations made prior to World War II, this difference in weight amounts to approximately 6% on the average.

Cost

The cost of a turbo-electric plant is somewhat more than that of a geared steam turbine plant. Based on information of installations prior to World War II, this difference amounts to about 5%. Of course it varies with different installations. It is possible that World War II has changed this, but it is hazardous to estimate the cost of the various types of plants today.

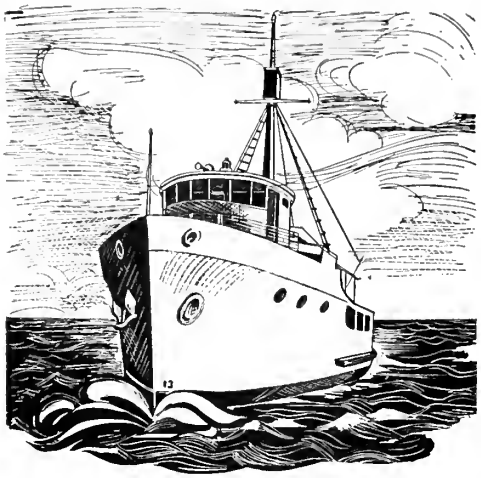
Suitability for Service

Where the turbo-electric drive fits into the marine propulsion field today depends on its special features such as:

(a) Greater flexibility in the arrangement of machinery;
(b) Full power for backing and maneuvering;
(c) Flexibility of operation;
(d) Use of the main propulsion generator for supplying electric power to equipment other than main propulsion; and
(e) Pilot house control.

During World War II, when the country's gear cutting facilities were taxed to the limit, many turbo-electric drives were installed. These installations, as well as ones installed prior to the war, have given good service. The applicable power ranges are from about 4000 up to about 50,000 SHP per shaft. Ships using this type of drive have a satisfactory cruising radius if the normal allotment of space and weight is allowed for in design of the vessel for fuel tanks.

Coast COMMERCIAL CRAFT



The Steel Tuna Clipper "White Star"

Built at Stockton, California, by Guntert and Zimmerman, the 350 ton steel tuna vessel White Star, recently completed her trial run and came up to every requirement of her owners, Van Camp Sea Food Company.

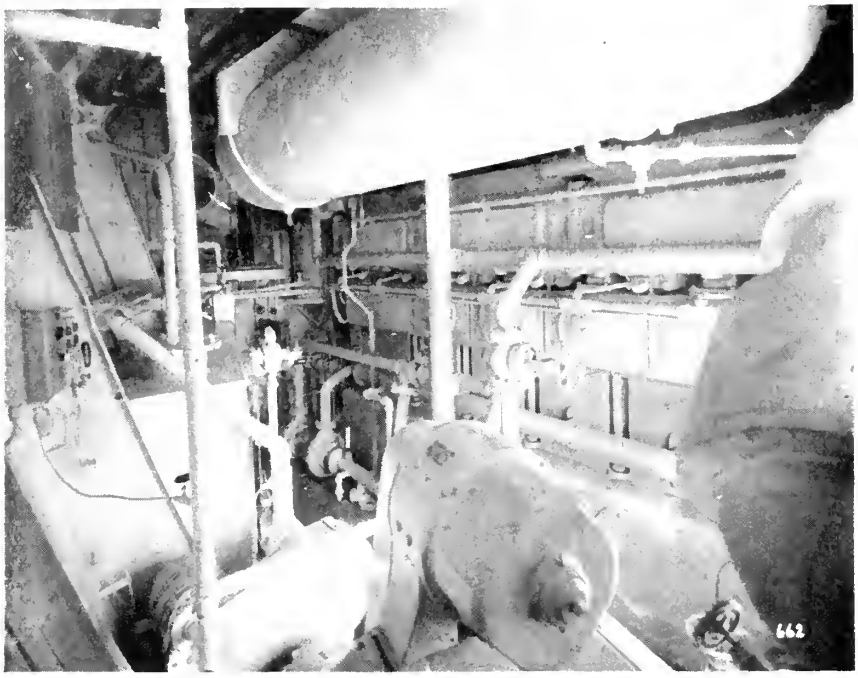
The ship was designed by W. C. Nickum & Sons, naval architects and marine engineers of Seattle. Contract was let to the Soule Steel Co., of San Francisco, but because of pressure of naval work in the Soule plant, was sublet to Guntert and Zimmerman.

The White Star is 138 feet long, with 32 foot beam and is the largest all-steel tuna clipper ever built. She will be the flagship of the Van Camp fleet. Equipped with a 1200 h.p. Enterprise engine, she has a cruising speed of 12½ knots and a cruising range of 12,000 miles. Refrigerated holds have a capacity of 475 tons of tuna. Total cost was $450,000.

A traditional feature of the ship is a chapel with an altar, customary with fishing craft likely to be manned by Portuguese sailors.

Record of Service

Within a few days after the attack on Pearl Harbor, former Van Camp tuna clippers had been taken over by the Navy and assigned to patrol and other duties. Often referred to as "floating ice boxes" they were inval-

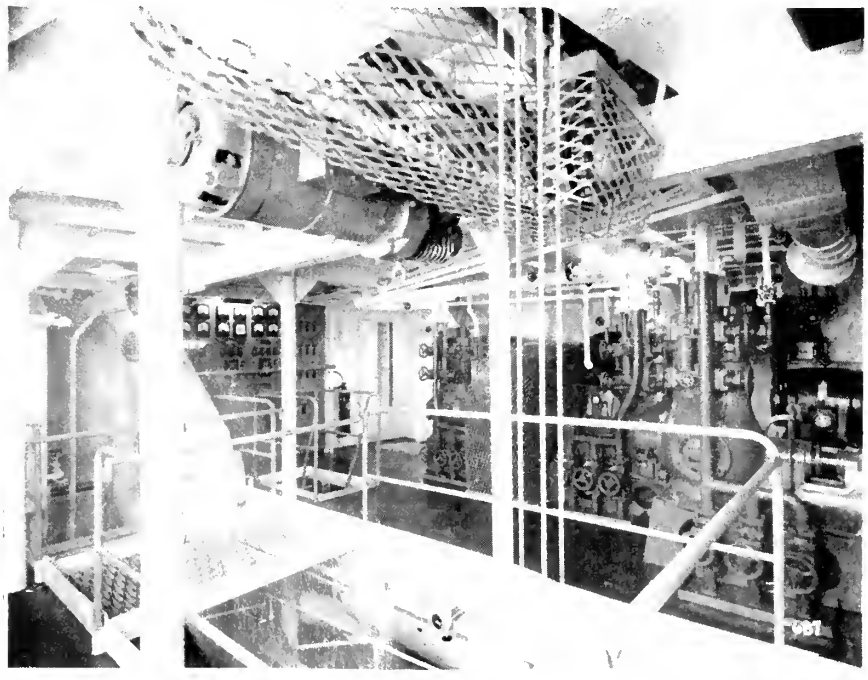


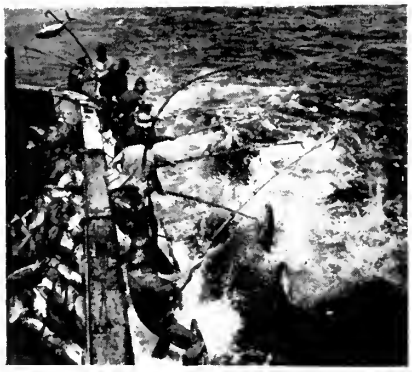
Main Enterprise Diesel engine, 1200 bhp.

uable in getting fresh meat, fresh vegetables and other foods to military installations on small South Pacific Islands which could not be reached by larger ships. On patrol duty, many former tuna clippers accounted for their share of enemy planes shot down.

"The value of these fishing boats was forcibly expressed by General MacArthur," said Gilbert Van Camp, president of Van Camp Sea Food Company, "when he stated that he would rather lose one of his bombing planes than one of the tuna clippers. This was high praise indeed, as everyone knows how few bombing planes MacArthur had in the South Pacific, especially in the early days of the war."

Baker refrigeration machinery in engine room.



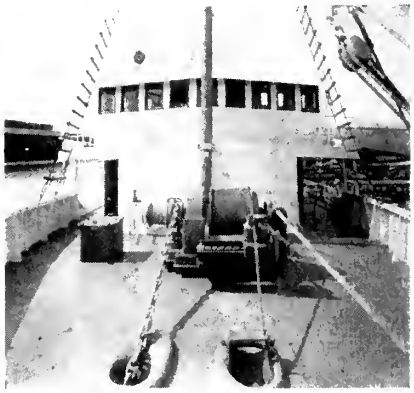


Fishing on the West Coast

Last year the fish catch in California was in excess of 550,000 tons This was split up about as follows:

Sardines	415,000 tons
Tuna	82,338 tons
Mackerel	30,000 tons
Fresh fish	25,000 tons

The total annual fishery of the entire United States including Alaska



View looking aft on upper deck, showing motor-driven anchor windlass.

averages around 2,000,000 tons per annum. Thus California produces in excess of 25% of the total fishery. The value of the fishery to the fisherman is around $35,000,000 per an-

Main Enterprise Diesel engine and Caterpillar Diesel-driven generator and pump.

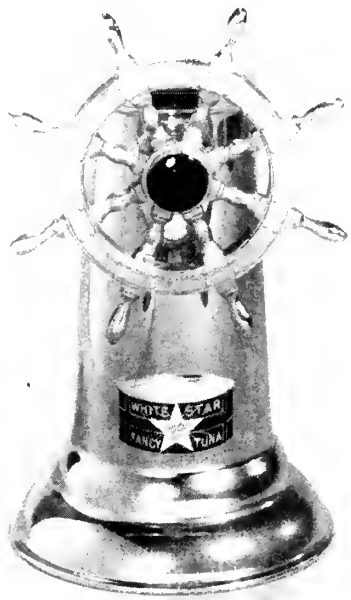
num whereas the value of the finished product at the producers' level is approximately $100,000,000 per year. Tuna fish accounts for half of the value both in its raw state as well as finished goods. The record catch of tuna occurred in 1940 amounting to 102,128 tons, but now that the tuna fishing fleet has been restored to above its 1940 capacity, it is expected that 1946 will establish an all-time high. As far as Gloucester is concerned, it does not begin to compare with the California fishery. Southern California fishery alone is greater than Gloucester.

Brine pumps and piping in passage between bait and fish holds.

Los Angeles-Long Beach Harbor again led all ports in the United States in number of pounds of fish caught during a year.

The harbor's total catch for 1945 was 441,180,000 pounds. This exceeded that of Boston by more than twice as many pounds, it being less than 200,000,000, although the value of the Boston port's catch is reported to have been more.

Steel hatches to fish and bait tonks on sheltered main deck.



A nifty cigar lighter souvenir distributed to guests at reception.

Pilot house with wheel stand, engine instruments and signals.

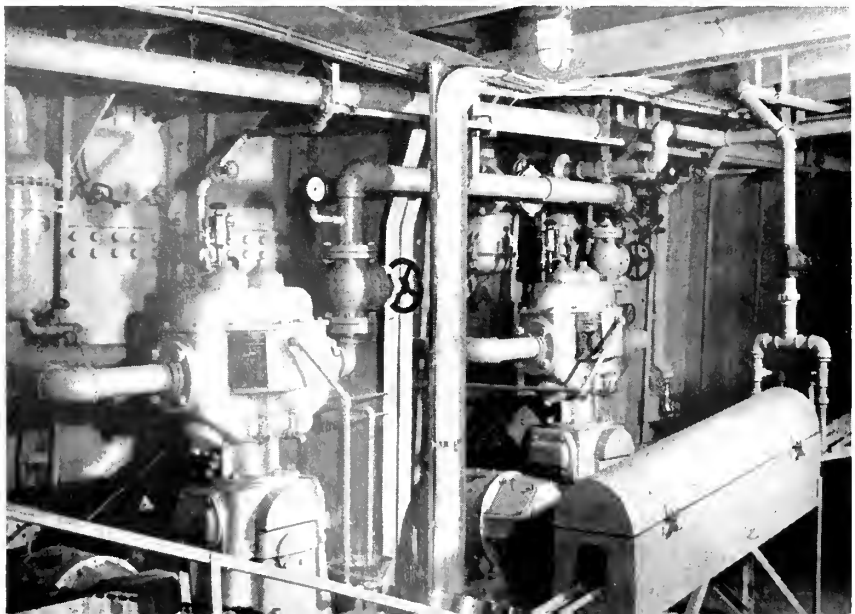
The below display of marine life was taken from the stomach of an "Irish Lord" weighing about 15 pounds (empty). Webster says it is a sculpin and that Bering sea natives like it for dinner. We would say it likes its dinner. The menu included crabs, sand sole, Tom cod, shiners, and candlefish, and what have you. The biggest fish in the picture is about eight inches long, just to give you an idea. A well-balanced diet with plenty of roughage. The "Lord" was captured at CRPA's Newport Station.

Cargo Vessel Converted To Cannery Ship

PORTLAND YARD COMPLETES $2,000,000 JOB

The Northwest Marine Iron Works, Portland, Oregon, has just completed the conversion of the 3500-ton Russian cargo ship Alma Ata to a modern crab and fish canning vessel. She will operate in the Okhotsk Sea, with Vladivostok as home port. Until last September, the conversion job was conducted as a lend-lease operation and was completed under a private contract between the Soviet purchasing mission and the repair yard. Total cost is said to be around $2,000,000 for the year-and-a-half job which included the dismantling of the entire original superstructure and construction of new and larger housing facilities for an increased number of officers, and also for cannery executives, an accounting office and a chemical laboratory as well as for the ship's crews, cannery labor, and fishing crews—a total of 515 persons.

The Alma Ata was built at Rotterdam in 1920 as the Maasdijk and was purchased by the Russian government in 1938. Her home port before the war was Odessa, whence she operated in general cargo trade. From Vladivostok she will remain at sea for nine months of the year, during which the catch of large Japanese crab, from April to August, and salmon from August to December, will be processed and canned and picked up by smaller ferrying vessels. From January to March she will remain in port.

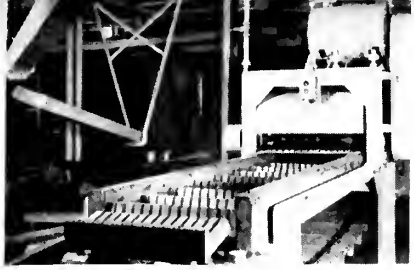


Can washer on cannery ship.

The outside skin of the ship is heavily insulated with rock wool and fiberglas to repel the extreme cold of the far north Okhotsk sea, while interior bulkheads throughout the quarters are finished of northwest plywood. A modern kitchen and large general mess hall for crew, cannery workers and fishermen is a feature.

Nine Boats Aboard

On the main deck are 18 two-ton davits for lifting and holding nine 42-foot fishing boats with their nets



Fish-cutting machine.

and catches and crews of seven men each, tanks for cooking the crabs, and a conveyor for transporting dismembered crab legs from the foredeck to the afterdeck, where shells are to be removed.

The actual canning equipment is placed on the second deck aft. Here are work tables where women will pack the cans, crimping machines for attaching the lids, six pressure cookers, and various conveyors and transport equipment for moving cans, cases and racks. All cannery workers engaged in the packing process must pass through a special wash room where they will be required to wash up before and after work to assure cleanliness.

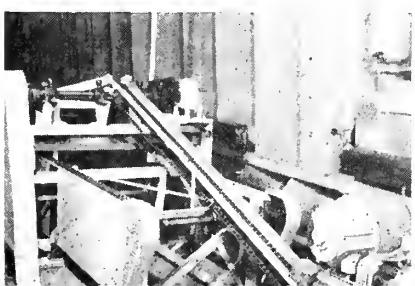
Of the ship's complement, 60 will be employed in ship operations and the remainder in fishig and cannery operations. One-half of the personnel will be women, many of them wives of the men employed.

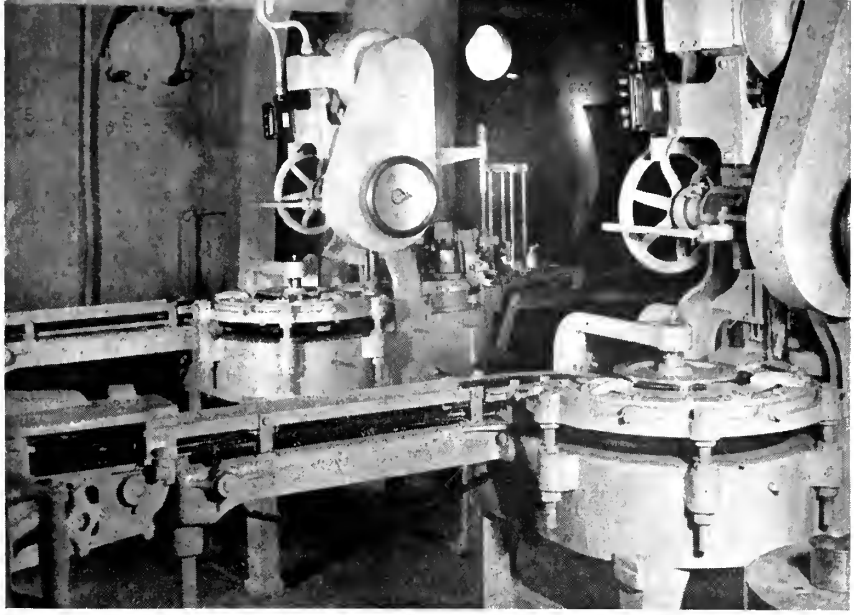
Quarters were built into the vessel for the 515 persons, who will be housed in rooms holding from one to ten persons, depending upon their positions. The lower decks amidships are finished up like those of a modern passenger vessel.

The vessel will be assigned a quota to meet, and if it exceeds the quota, the crew divides the surplus earnings among the various individuals who participated in catching and canning.

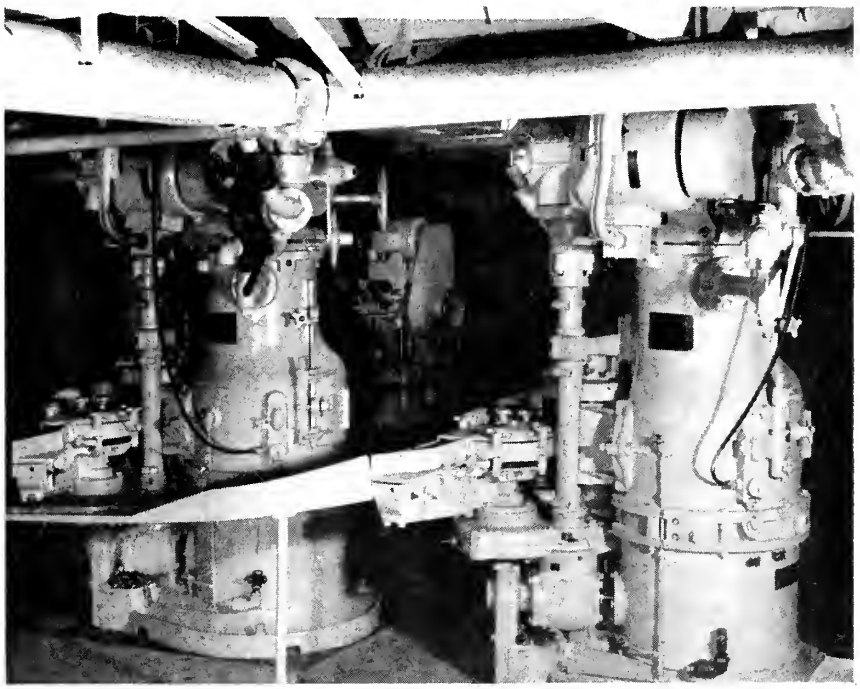
One other crab cannery ship, the Vsevold Sibertsev, was converted in Portland during the war by Poole, McGonigle & Jennings, while two similar vessels, the Mengensky and Chernyshevsky, were converted at San Francisco, all for operations in the Sea of Okhotsk.

Conveyor carrying cans to retorts for cooking.



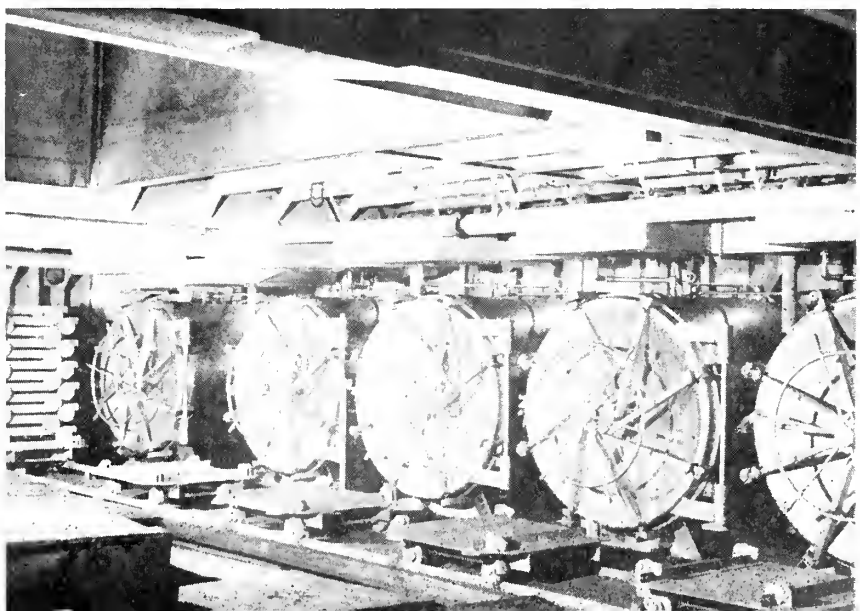


Can clinching machines, which clinch flange of can around top loosely.



The two vacuum machines which receive cans from clinchers. These tanks are vacuumized and after can has had all air removed, it has top sealed permanently while still in tank.

Six steam retorts in which sealed cans are cooked. Time for cooking is about 20 minutes. Retort capacity, 600 cans each.

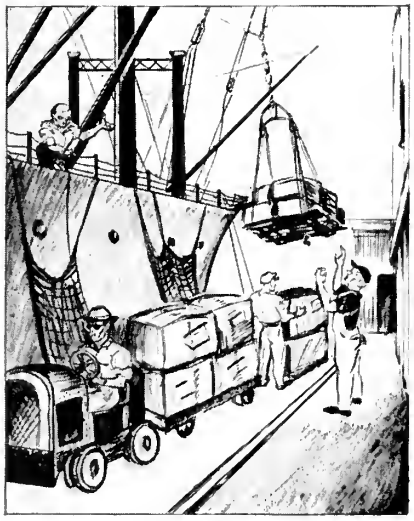


Admiralty Decisions

By Harold S. Dobbs
of the San Francisco Bar

Stevedore or Seaman?

It has been repeatedly held that a stevedore has the same status as a seaman insofar as his right to recover on a basis of breach of warranty of seaworthiness, provided the stevedore is actually engaged at the time of his injury in the loading or unloading of cargo. This rule is rather generally accepted and, therefore, it is interesting to review the decision of **John Bruszewski** vs. **Isthmian Steamship Company** (1946 A.M.C. 223), United States District Court (EDP), where the court makes



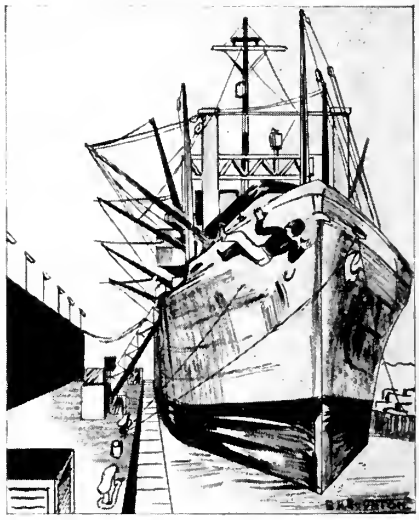
Longshore work.

a finding that the stevedore was not engaged in loading or unloading and, therefore, not entitled to rely for the proof of his case upon the warranty of seaworthiness. The court entered a directed verdict on behalf of the defendant at the close of all of the evidence in the case and the plaintiff subsequently filed a motion to vacate the judgment.

The plaintiff was a longshoreman in the employ of a stevedoring contractor who, together with eight other men, comprised a gang of nine who were ordered to report aboard the vessel George Read. The ship's officers refused to provide any men to repair a boom that had been broken and which was delaying the loading of the vessel and, therefore, the stevedoring gang were procured to repair it. The plaintiff, as a member of the nine man gang, reported to the vessel and proceeded to repair the broken boom which, by the way, was the only job that they were called to do. This gang took over the exclusive job of repair as well as operating the winch. Plaintiff was struck on the head when the block attached to the boom came loose. The plaintiff was seriously injured.

The vessel was operated under a so-called general agency agreement between the United States and the Isthmian Steamship Company. They served the vessel in accordance with the terms of the agreement. The contract designated the defendant as general agent of the United States and obligated it "to manage and conduct the business for the United States in accordance with such directions, orders or regulations as the latter has prescribed or from time to time may prescribe, and upon the terms and conditions herein provided of such vessels as have been or may be by the United States assigned to and accepted by the general agent for that purpose." The contract further provided that the agent should collect monies due, equip, supply and maintain the vessel among other things, subject to the direction and inspection of the United States. The master, under the agreement, was employed as an employee of the United States and the other officers and men required to fill the complement of the vessel were also employed as employees of the United States, subject to the orders of the master.

In directing a verdict for the defendant at the close of all of the evidence, the court first resolved that the general agency agreement constituted the defendant an owner **pro hac vice.**[1] A studied consideration of the provisions of the general agency agreement leaving possession and management of the vessel to the defendant gave it such a substantial measure of control over its operation, that the powers reserved to the United States under it were not such as would deprive the defendant of **de facto** control of the vessel, which is the criterion to be adopted in making a determination. **Brady** vs. **Roosevelt S. S. Co.** (317 U. S. 575, 1943 A. M. C. 1); **McCormick** vs. **Moore-McCormack Lines, Inc.** (1943 A. M. C. 1422, 54 Fed. Supp. 399). While it is true that some factual differences obtain here which are not to be found in the **Brady case,**[2] in that the master in the instant case was an agent and employee of the United States, and that it was the duty of the gen-



Not longshore work.

eral agent to procure and make available to the master, the officers and crew who were to be subject only to the master's orders, yet these differences are not controlling. An overall consideration shows that with the possession of the vessel in the defendant and its management and direction in it likewise, there was such a sufficient control and responsibility in the defendant as to give it the status of operator, and owner **pro hac vice,** and whatever differences obtain in the instant agreement and those which were set out in the agreement under consideration in the **Brady** vs. **Roosevelt case,** they were not such as

[1] For the occasion.
[2] See April Pacific Marine Review.

would divest the defendant company here of **de facto** control.

The next consideration to be determined by the court was whether or not the defendant company being the owner and operator **pro hac vice** was liable for the injuries occasioned to the plaintiff. The plaintiff placed main reliance for liability of the defendant upon the unseaworthiness of the vessel, and while he averred certain acts of negligence in his complaint no evidence was introduced at the trial in support of them.

The plaintiff took the position that, since he was employed as a stevedore, he had the same status as a seaman, and recovery may be had against the ship owner on the basis of breach of warranty of seaworthiness, which warranty is not dependent upon a showing of negligence. **Mahnich** vs. **Southern Steamship Co.** (321 U. S. 96, 1944 A. M. C. 1). He further asserted that the doctrine of the assumption of risk was not applicable in this status either. **Socony-Vacuum Co.** vs. **Smith** (305 U. S. 424, 1939 A. M. C. 1). The asserted authority for this position is **Joseph Sieracki** vs. **Seas Shipping Co., Inc.,** and **Bethlehem Sparrows Point Shipyard, Inc.,** Bethlehem Steel Company (1945 A. M. C. 407). In that case the court extended the protection afforded seamen to stevedores when actually engaged upon a ship, **in the loading or unloading thereof.** It did not attempt, however, to give a stevedore as such, all the rights, privileges and protection offered a seaman under the maritime law. As a matter of fact the court stated: "We do not hold that a stevedore is entitled to everything that a seaman may claim. All we are deciding now is that if he is injured on the ship in the course of unloading or loading the vessel he may have redress for a defect caused by its unseaworthiness." In other words, the court, not alone here, but throughout the opinion, limited the extension of the doctrine to the loading and unloading of a ship by a stevedore, or when he is performing a function essential to maritime service upon a ship. Here, however, no such situation obtains. The work the plaintiff was called upon to perform was in no sense essentially a maritime service, as the testimony shows the crew of the ship were not able to do the work and as a matter of fact the boastwain testified that the repair of the boom was a job for a shipyard. Again, the testimony shows that repair of the boom was the only purpose for which the plaintiff and the rest of the stevedore gang were called to the ship and that it was not an ordinary function for them to perform but in reality an unusual one. Accordingly, the test is not to look at the label given the individual but rather at the nature of the work he is called upon to do and, if a finding thereof shows it to be essentially one of a maritime nature, such as loading or unloading a vessel, then the criteria of the **Sieracki case** are met and the protection of a seaman can be afforded to a stevedore. If, however, the nature of the work is one which seamen do not ordinarily do or can do, as the testimony here shows, or if it partakes as here of a purely mechanical nature, the repair and removal of a piece of machinery, then it falls without the doctrine of the **Sieracki case,** and the plaintiff is relegated to a showing of actual negligence on the part of the ship owner in order to recover, as well as to be subject to other defenses such as the doctrine of the assumption of risk. Furthermore, in order to recover on a breach of the warranty of seaworthiness, it is essential that the vessel be unseaworthy with respect to the instrument whereby his injuries were occasioned. **Cassil** vs. **United States Emergency Fleet Corporation et al.** (1923 A. M. C. 655, 289 Fed. 774). Here, it would be a contradiction in terms, to say that there was a warranty of seaworthiness of the instrument occasioning the injury, when the instrument was a broken boom, the repair of which was the only reason for plaintiff being on the vessel at all. The court gave consideration to the further issue of assumption of risk, finally deciding that risk was assumed in this case because of the peculiar circumstances in this case.

Privileged Communications

The courts are constantly called upon to decide whether or not counsel representing defendants or respondents are required to produce the statements of witnesses taken immediately after an accident or injury of one kind or another. It has been claimed and subsequently held in many cases that defendants' or respondents' counsel must produce such statements prior to trial upon the request or motion of plaintiff or libelant. The courts theorize that each party is equally entitled to the information contained in the statements before trial. In **Shields et al.** vs. **Sobelman et al.** (U.S.D.C., Pa.), plaintiff's counsel filed a motion in the aforementioned district court requesting an order upon defense counsel to produce certain photographs of a winch, which was the physical instrumentality causing a serious accident to the plaintiff, which accident was the subject matter of a civil action pending in the aforementioned court. Plaintiff claims that the decision in the Circuit Court of Appeals in **George E. Hickman** vs. **John M. Taylor et al.** (1946 A.M.C. 1), is decisive in the case. It appears that shortly after the accident at a time when there was more than a probability that a claim would be made in respect of it and that litigation would ensue, Mr. Byrne, acting as attorney for a defendant in another case arising out of the same accident, went to the vessel with a photographer and personally directed and supervised the taking of the photographs in question, pointing out "just exactly what part of the particular machine was involved," having in mind, "what I wanted to show bearing upon liability or lack of liability in this case."

The question presented is not free from doubt. There is little distinction between the statement of a witness taken by a lawyer and a photograph taken for all intents and purposes also by a lawyer. Of course, the lawyer does not actually press the release of the camera that takes the picture, and does not develop the photographs; but they are made as he directs and they are evidence in the case, exactly as the statement of a witness is evidence in the case, and into them both go some of his legal knowledge as to what is relevant and what is not, and what evidence it behooves his client to be prepared to present.

In the **Hickman case** it appears that a distinction is made between a machine or a part of one which has hurt someone, and which may be in a lawyer's hands, and the statements of witnesses which the lawyer takes of witnesses. The opinion says that a piece of a machine which has hurt someone is among the things which "are not to be concealed until the day of trial for that reason." On the other hand, the court says the statement of a witness is an intangible

Regulations to Govern Sale And Charter of War-Built Fleet Issued by M. C.

Announcing that detailed regulations under the Merchant Ship Sales Act of 1946 were filed April 22, with the Federal Register, the Maritime Commission made known that it would now accept applications for the purchase or charter of dry cargo vessels and tankers built during World War II.

In awarding ships on the basis of applications, the Commission will observe certain preference requirements of the Ship Sales Act, including preference of citizens over non-citizens and consideration of an applicant's wartime tonnage loss.

"To allow for uniformity and equal treatment in the application of these preference standards the Commission has provided that all applications received in a given calendar month will be treated together," the Commission declared. "The first preference period will expire June 1, 1946. Citizen applications received during one calendar month will take precedence over all applications received in later calendar months."

A Commission press release issued simultaneously with filing of the regulations emphasized that citizen applicants will lose preference if they intend to transfer the vessel to a foreign flag, and that the Commission will not approve transfer of a P-2 or other passenger vessel, Liberty-type collier, or tanker to foreign registry after acquisition.

The regulations are contained in General Order 60, made part of Title 46—Shipping-Chapter II-U. S. Maritime Commission-Subchapter F-Merchant Ship Sales Act of 1946 - Part 299 - Rules and Regulations, Forms, and Citizenship Requirements - of the Code of Federal Regulations.

"The orderly sale of war-built vessels", the Commission stated, "is expected to re-establish a privately-owned American merchant fleet composed of modern vessels able to meet all normal competitive standards.

"Purchasers of the war-built vessels must pay at least 25 per cent down and the balance in annual installments over the 20-year life of the vessel, with 3½ per cent per year interest on the unpaid balance."

General Order 60 describes each of nine standard types of war-built vessels to be sold and lists their estimated pre-war domestic cost of construction, actual domestic war cost of construction, their statutory sales prices and floor prices in accordance with provisions of the Ship Sales Act. The price data contained in General Order 60 is as follows:

This table was a part of a preamble to General Order 60 outlining statutory requirements for the applications for acquisition of ships under the Ship Sales Act. The regulations cover nearly 80 mimeographed pages and include the necessary applications and forms to be used by applicants for purchase or charter of the ships.

"The Merchant Ship Sales Act of 1946 having been enacted on March 8, 1946, and the pre-war domestic cost of vessels covered thereby being published in this issue of the Federal Register pursuant to such Act, in section 299.56 below," the preamble to the regulations states, "the Maritime Commission will accept applications under the provisions of the Act and the following regulations. Subject to such provisions, the Maritime Commission will accept applications for the purchase or charter of vessels now under the jurisdiction and control of the Maritime Commission or

PRICES FOR STANDARD MARITIME COMMISSION VESSELS IN ACCORDANCE WITH THE MERCHANT SHIP SALES ACT OF 1946

TYPE VESSEL	Estimated Cost as of Jan. 1, 1941	Domestic War Cost	Statutory Sales Price (Unadjusted)	Price-Floor
DRY CARGO			50% 1941 Cost	35% War Cost
C1-MT-BU1	$1,063,000	$1,396,813	$ 531,500	$ 488,885
C1-M-AVI	1,280,000	1,982,464	640,000	693,862
C1	1,940,000	2,608,168	970,000	912,859
C2	2,100,000	2,736,624	1,050,000	957,818
C3	2,460,000	3,659,228	1,230,000	1,280,730
C4	3,300,000	4,420,965	1,650,000	1,547,338
VC2-S-AP2 (Victory-15K)	1,958,000	2,511,877	979,000	879,157
VC2-S-AP3 (Victory-17K)	2,130,000	2,872,659	1,065,000	1,005,431
N3	760,000	1,339,477	380,000	468,817
				31½% War Cost
EC2-S-C1 (Liberty)	1,278,000	1,728,590	639,000	544,506
TANKERS			87½% 1941 Cost	50% War Cost
T1-M-BT	994,000	1,774,038	869,750	887,019
T2-SE-A1 (14K)	2,316,000	3,010,703	2,026,500	1,505,352
T3-S-A1 (15K)	2,175,000	2,970,029	1,903,125	1,485,015

War Shipping Administration. (No charter agreement will be entered into prior to 60 days from date; and no contract of sale to a non-citizen of a tanker or C-type vessel will be entered into within 90 days from date, except as provided in the Act). Additional vessels will be available at such time as they may be transferred to the jurisdiction and control of the Maritime Commission or War Shipping Administration. The pre-war domestic cost of certain special types of vessels are not included in this publication, but will be published at a later date, after which applications for ships of such types will be entertained."

Announcing issuance of the regulations, which bore the approval date of April 13, 1946, the Commission pointed out that the sale of the ships differs from sale of other surplus war property in that the Merchant Ship Sales Act of 1946, under which the sales will be made, places responsibility upon the Maritime Commission to consider applications for purchase or charter of the vessels according "to regulations (General Order 60) issued today, and in the light of maritime policy expressed by the Ship Sales Act and also the Merchant Marine Act of 1936."

Approved sales and charters will eventually be announced by the Commission, but applications pending for Commission consideration will be held confidential, it was stated today.

Foreign Applications

An official of the Commission declared that that agency has been approached by representatives of France, Italy, Norway, Britain, Poland, most of the Latin Amercian maritime countries, and others, as to the possibility of acquiring, in most cases, some small freighters under the Ship Sales Act.

Questioned whether foreign nations might use American capital to purchase any war-built ship, this official declared it is his understanding that the Export-Import Bank will not lend money to foreign nations for the purpose of acquiring American-flag tonnage. He expressed the belief that all established American Steamship lines would get their applications before the Commission shortly and that the first month or two, after issuance of the regulations, would be the heaviest workload on the Commission.

Exchanges

Exchange by a purchaser of a war-built vessel of an old vessel for an allowance of credit on the new ship is provided for by the statute, the Commission pointed out, the purpose being to encourage retirement of obsolete vessels from the American merchant marine. However, Commission officials conceded they do not expect to get rid of "all the old crocks" in operation.

"To provide for uniform treatment of all purchasers of war-built vessels," the Commission stated, "provision is made for adjustment of prices paid on war-built vessels which were sold under other legislation and delivered to their owners prior to the passage of the Ship Sales Act. The readjustment has the effect of selling the vessel to a purchaser as of March 8, 1946, the date of passage of the Ship Sales Act, and under its terms. This changed date of sale requires recomputation of vessel cost."

The Commission also cited the fact that war-built dry cargo ships may be chartered by American citizens, but only after they have first been offered for sale, and that charter rates normally will not be less than 15 per cent per year of the statutory sales price. In addition, it was cited that applications will be considered from non-citizens (except for purchase of passenger vessels and Liberty-type colliers and tankers) provided such sales are consistent with the national and foreign defense policies of the United States, and only after American citizens have had a reasonable prior period in which to buy or charter. Citizens of the Philippines will have preference over other non-citizens up to July 4, 1946, it was added.

Vessel Inventory Directions For Ships Redelivered To W. S. A.

Directions as to the taking of inventories of vessels owned by the War Shipping Administration, when such ships are redelivered to WSA by a General Agent for simultaneous delivery to another General Agent have been issued by WSA in Supplement No. 2 to Operations Regulation No. 37, under date of April 18, 1946. The supplement reads as follows:

Operations Regulation No. 37—Supplement No. 2—Pertaining to all vessels owned by W. S. A. (Dry Cargo and Passenger Vessels & Tankers).

Subject: Vessel Inventories—WSA Owned Vessels.

Effective immediately, all War Shipping Administration owned vessels which are redelivered by a General Agent to the WSA for simultaneous delivery to another General Agent shall be physically inventoried by personnel assigned by the respective General Agents. The WSA will assign one qualified Observer to each vessel who will report on the accuracy and completeness of the inventory.

These instructions apply only to WSA owned vessels being redelivered from a General Agent for simultaneous delivery to another General Agent and do not apply to redelivery of vessels being operated for the WSA under bareboat or time charter agreements.

The responsibility for preparing the necessary typed priced inventories shall rest with the General Agent redelivering the vessel and detailed instructions as to form, distribution, number of copies required, etc., will be furnished all General Agents for their guidance in this respect.

Expenses necessarily incurred by virtue of complying with the foregoing shall be chargeable to the Agent's overhead account.

Policy Change Proposal to Be Laid Before Maritime Commission

Future shipping policies relative to subsidized versus nonsubsidized shipping, and the extent to which the Maritime Commission will encourage equal treatment in the servicing of all trade routes, will come before the Commission for consideration in the near future.

Commissioner Edward Macauley, Vice Chairman of the maritime agency, has prepared a series of suggested statements for consideration by the Maritime Commission, including a suggestion that the Commission should consider two subsidized lines to operate on the same route where it is shown adequate service for that route is not available.

Isthmian Becomes Associate Member of Pac. Westbound Conference

Modification of the agreement of the Pacific Westbound Conference so as to permit Isthmian Steamship

Co. to participate in contracts made by the Conference without necessity of posting a bond or becoming a voting member of the Conference has been proposed by the Isthmian Co. and member lines of the Conference. The basic agreement of the Conference is Maritime Commission Agreement 57, and the modification is designated 57-19.

Under terms of the proposed modification Isthmian agrees to abide by all the rates, rules, regulations and decisions of the Conference. The agreement modification is not to become valid and binding until approved under provisions of Section 15 of the 1916 Shipping Act.

Seven Wartime Regulations Are Revoked by W. S. A.

Lifting a number of wartime regulations with respect to the operation of merchant vessels controlled by the War Shipping Administration, that agency has revoked seven Operations Regulations. Issued under date of April 15, 1946, all of the revocations were made effective as of March 1, 1946.

Due to wartime security regulations some of the original regulations now revoked were not carried by us in our Letters. Rules revoked are:

Operations Regulation No. 14—issued October 12, 1942—prescribing procedure regarding advice to agents of WSA vessels transiting Panama Canal or calling at Canal Zone ports for bunkers or orders;

Operations Regulation No. 35—providing for assignment of Navy armed Guard to merchant ships owned by or under charter to WSA;

Operations Regulation No. 40—prescribing health precautions for WSA ships going to the West Coast of Africa;

Operations Regulation No. 56—issued May 12, 1943—providing for issuance by agents and general agents to masters of vessels a copy of pamphlet containing instructions relative to anti-gas measures and decontamination procedure (covered in our Letter No. F-626, of May 13, 1943);

Operations Regulation No. 61—issued June 7, 1943—providing for use of Form OPA R-544 for acknowledgment of delivery of bunker fuel and diesel oil, gasoline and kerosene—all rationed oil products (covered in our Letter No. F-645, of June 8, 1943);

Operations Regulation No. 76: issued November 6, 1943—relating to prisoners of war and requiring that notices be posted on ships' bulletin boards instructing crew members as to their conduct and rights when, after sinking of a vessel, they are questioned by warship commanders; and

Operations Regulation No. 81—relating to convoy conferences.

Wheeler Proposes Establishment Of Federal Traffic Bureau

Establishment of a Federal Traffic Bureau to negotiate and make contracts for transportation of Government traffic and perform other functions relating to such traffic would be provided for by a bill (S. 2088) introduced in the Senate by Senator Wheeler, Montana, Chairman of the Senate Interstate Commerce Committee, to which the measure was referred for consideration. Powers, duties, and responsibilities of all departments and agencies of the Government relating to such matters would be transferred to the proposed Bureau.

Powers of the Federal Traffic Bureau would extend to transportation subject to regulation under any part of the Interstate Commerce Act, as amended, the Civil Aeronautics Act of 1938, as amended, the Shipping Act of 1916, as amended, the Merchant Marine Act of 1936, as amended, and the Intercoastal Shipping Act of 1933, as amended. The Bureau would be charged with maintaining a continuous investigation into the justness and reasonableness of all present and proposed tariffs in so far as they shall relate to or concern, directly or indirectly, all actual or potential Government traffic.

Seamen Brought Under Minimum Wage Provisions In Bill Passed by House

Legislation to amend the Fair Labor Standards Act of 1938 was passed by the Senate and referred in the House to the House Labor Committee for consideration. The bill (S. 1349) was materially amended in the Senate following report from the Senate Committee on Education and Labor, but as passed by the Senate includes seamen under the minimum wage provisions of the statute, but excludes such employees from the maximum hours requirements. As passed by the Senate the minimum wage for employees engaged in commerce would be fixed at not less than 65 cents an hour.

Cates Named Executive Assistant to M. C. Vice Chairman

Designation of John M. Cates, Jr., Assistant to Commissioner, to serve as Executive Assistant to the the Vice Chairman has been made by Acting Maritime Commission Chairman Edward Macauley. Mr. Cates will act for and on behalf of the Vice Chairman as directed by him and will coordinate special activities under the supervision of the Vice Chairman. In addition, he will serve in the capacity of special assistant to the Acting Chairman.

Ruling on Waterman Case: Supreme Court Holds Red Sea Charters Are Renegotiable

Profits derived by steamship companies from operations under Red Sea charter contracts with the British Ministry of War Transport are subject to renegotiation by the Maritime Commission under terms of the Renegotiation Act, and claims to the contrary by the carriers cannot be brought into court pending exhaustion of the administrative remedies provided by law, the United States Supreme Court ruled.

The decision of the high court was handed down by Justice Black in the case (Docket No. 435, October Term, 1945) of Edward Macauley et al., Petitioners, vs. Waterman Steamship Corporation. Justice Douglas "concurs in the result," and Justice Jackson took no part in the consideration or decision of the case. No dissenting opinion was presented.

In all, nineteen carriers participated in the Red Sea charters, but two of them—the American President Lines and Weyerhaeuser Steamship Company—submitted their profits to renegotiation by the Commission. The remaining 17 cases, through mutual agreement, were held in abeyance pending the high court's ruling in the Waterman case.

W. S. A. Calls Upon Coastal Operators for Data on Cargoes, Ships, Revenues, Etc.

Cooperation of coastal and intercoastal ship operators in the resump-

tion of normal peacetime traffic has been enlisted by the War Shipping Administration, Acting Administrator Granville Conway announces. He added that, in order to meet an acute need for moving cargoes, WSA has worked out a four-point program calling for information as to cargoes and ships available, operating expenses and revenues, and the Government initiation of service which will be continued by private operators.

The program is linked with the WSA petition filed last week with the Interstate Commerce Commission requesting investigation of the lawfulness of existing railroad freight rates and practices which are competitive with the domestic water carriers.

Specifically, the WSA program asked the operators to—

(1) Survey types and amounts of cargoes to be moved.

(2) Survey types and numbers of ships available.

(3) Estimate operating expenses and revenues of operators.

(4) Comment upon initiation, under Government supervision, of service to be continued by private operators.

WSA asked that operators who have not already made surveys of ship requirements and studies of operating costs and revenues undertake them immediately and complete them as soon as possible. It was suggested that, to assist themselves, the operators make prompt adjustment of such pre-war rates as "the distorted rail tariffs may competitively permit." Lines that have not already done so were asked to study all possibilities of rate improvement, the WSA announcement said, and added:

"Based upon the survey of potential cargoes, revenues, types and numbers of ships available, the plan calls for the initiation of coastwise and intercoastal service by WSA through the agency of carriers authorized to operate under the Interstate Commerce Act. Limited common carrier services have already been initiated between North Atlantic-South Atlantic-Gulf of Mexico and the Pacific Coast, and in the Pacific coastwise trade. WSA officials pointed out that these services were expected to become self-sustaining after an initial period at least to the point of covering operating expenses."

Matson-Railway Express Agreement Filed for Maritime Commission Approval

An agreement (No. 7571) between Matson Navigation Company and the Railway Express Agency, Inc., under which Matson will transport the business of the express agency between San Francisco or Los Angeles and the Hawaiian Islands, has been filed with the Maritime Commission for approval.

Under the arrangement, Matson is relieved from liability in the handling of money, currency, gold coin, valuables, and merchandise on which Railway Express Agency, Inc., is to carry marine insurance as per contract between it and the tranportation companies over which lines it may pass.

Appointments in Maintenance And Repair Division Made by W. S. A.

Appointment of Directors and Assistant Directors of the Division of Maintenance and Repair of the War Shipping Administration for Atlantic and Pacific Districts has been made by that agency.

C. H. Kennerly has been named Director and C. F. Pitzer, Assistant Director, of the Division-Atlantic. These appointments are effective as of January 28, 1946.

A. D. Ells was appointed Director and James Scott, Assistant Director, of the Division-Pacific. Mr. Ells' appointment was made effective as of February 25, 1946, and that of Mr. Scott as of March 12, 1946.

Bills to Provide Freight Refunds For Frustrated Voyages Opposed by M. C.

Enactment of pending legislation providing for the refund by the United States of freight money paid for transportation of cargoes on voyages frustrated by the outbreak of the war in December, 1941, is opposed by the Maritime Commission, Acting Chairman Edward Macauley advised Representative Bland, Virginia, Chairman of the House Merchant Marine Committee, in a letter dated March 22, 1946. The letter has been incorporated in a Committee Document (103).

The bills involved in the communication were H.R. 2633, to authorize the refund by War Shipping Administration of certain freights for transportation on frustrated voyages, and H.R. 3802, a bill to amend Public Law No. 41, 78th Congress. That Public Law was enacted in the 78th Congress and authorized WSA to refund the freights as to certain frustrated voyages. Judge Bland asked the Commission on November 11, 1945, for a report on the two pending bills, Acting Chairman Macauley stated in his letter.

Non-Subsidized Lines Ask Revamping of Ship Tax Procedure

A general revamping of procedure under law relative to the make-up of reserve funds established by American steamship operators, so as to place subsidized and non-subsidized lines on the same footing as to complete tax exemption, is asked by representatives of non-subsidized lines, in testimony presented to the House Merchant Marine Committee. GEORGE W. MORGAN, Association of American Ship Owners, took the position that if it is sound policy through the "liberal provisions of Section 607" of the 1936 Merchant Marine Act to encourage twelve subsidized companies to accumulate their capital for ship replacement purposes, tax free, it would "seem equally desirable to offer the same encouragement and liberality to the unsubsidized companies."

In addition, DONALD MORRISON, Vice President, American-Hawaiian Steamship Company, appeared to support Congressional sanction of efforts of some shipowners, who have established construction reserve funds under Section 511 of the 1936 Act, to also take advantage of the replacement fund procedure under Section 112(f) of the Internal Revenue Code with respect to the same proceeds, that is the proceeds from the similar ship losses by sinking, requisition or otherwise. The Commissioner of Internal Revenue, sometime back, denied this latter permission, holding that the taxpayer was required at the outset to choose between the two alternative procedures and that having once deposited the proceeds from an involuntary conversion in a construction reserve fund under Section 511 of the 1936 Act, he was thereafter foreclosed from replacing the lost property under the involuntary conversion provisions of the Internal Revenue Code.

Chart Program of the Hydrographic Office

By Rear Admiral R. O. Glover, USN

Hydrographer of the Navy

WARTIME PRODUCTION

To meet the demands of naval operations, air action, and amphibious assault, wartime chart production at the Hydrographic Office skyrocketed to many times its peacetime level. From a pre-war average of 1,000,000 charts per year, the Hydrographic Office increased its output to over 45,000,000. New charts were developed at the rate of nearly 1,000 per year as compared with 60 in pre-war years. Hydrographic Office charts, other than combat charts, were used by all vessels of the United Nations in transporting men and materials to every fighting front in the world. In normal times the work of the Hydrographic Office had been carried on by 200 civilian career men. At its peak during the war the personnel numbered 1,800 including officers and enlisted personnel of the Navy in addition to an enlarged civilian staff. Work was organized on a 24-hour basis with three shifts of workers.

This article deals with the wartime production. The peacetime program will be described in our June issue.

Constructing a photogrammetric radial-lined plot of shoreline and topography from aerial photographs, using metal templates.

For more than a hundred years, the Hydrographic Office has served not only the United States Navy, but also an expanding Maritime Service and private commercial enterprise. Its charts cover every part of the seas and oceans, and its services fill every need of the navigator. The war made greater demands upon the Hydrographic Office than it has ever been called upon before to fulfill. That it satisfied these demands is evident from the following commendation from Admiral Nimitz:

> "The efficiency and promptness with which the Hydrographic Office has filled my needs has been and is an important contribution in offensive action against the Japanese Forces."

It is only recently that the Hydrographic Office has been able to reveal the manner in which many of these needs were met.

During the present post-war period and in the future, the Hydrographic Office will turn its full attention once more to the job of providing navigational charts and nautical publications, sailing directions, aeronautical charts and publications, and various books of tables and scientific information for navigators of the United States Navy and Merchant Marine.

When called upon to produce the varied charts necessary for conducting an offensive war in the Pacific, the Office found very few charts and little information of any value was available on such important spots as Guadalcanal, Bougainville, Truk, Tarawa, Kwajalein, Saipan, Iwo Jima, or Okinawa. Some of these islands had been held under League of Nations Mandate by the Japanese for more than twenty years and our ships had not been permitted to enter those waters. Charts available were known to be obsolete. It was necessary, therefore, not only to construct

Plotting the position of the ship with a three-arm protractor in order to place the position of soundings.

the many and complicated types of charts necessary for the precision accuracy of modern warfare, but also to go out and collect the basic information about the areas. In this, the survey ships of the Hydrographic Office and the planes of the fleet and the army took a most active part. Only recently have their activities and the types of charts and information subsequently produced been revealed for public knowledge.

Many new methods and shortcuts were devised to speed up production of the vitally needed charts and tables. Among the special types of charts produced were combat charts made for use in direct enemy attack. loran navigational charts for use with a new and then secret radio navigational aid, waterproof surface current and temperature charts for the aid of persons lost at sea, special air target charts, sea and swell charts, for seaplanes and aircraft carriers, bottom sediment charts, and other oceanographic information for use in the many amphibious landings.

In addition the Hydrographic Office continued to produce: pilot charts, nautical charts, notices to mariners, sailing directions, hydrographic bulletins, daily memoranda, ice supplements and aeronautical information.

Wartime Surveying

When the United States took over the defense of Greenland, hydrographic engineers were sent to work with the Greenland Ice Patrol to survey areas selected for bases. Lend-lease bases necessitated also surveys in various areas from Newfoundland to the Galapagos Islands.

After Pearl Harbor the work of the Hydrographic survey ships changed from dull routine to "never a dull moment," according to Commander Irving Johnson, Skipper of the USS SUMNER. Formerly employed in charting areas of commercial importance chiefly in the Americas, these ships were shifted to areas of military importance. All of the scientific aids to hydrographic surveying developed during the past quarter century were put to use. Among these aids are the fathometer, the wire drag, the aerial camera, taut wire measuring gear, and radio acoustic ranging.

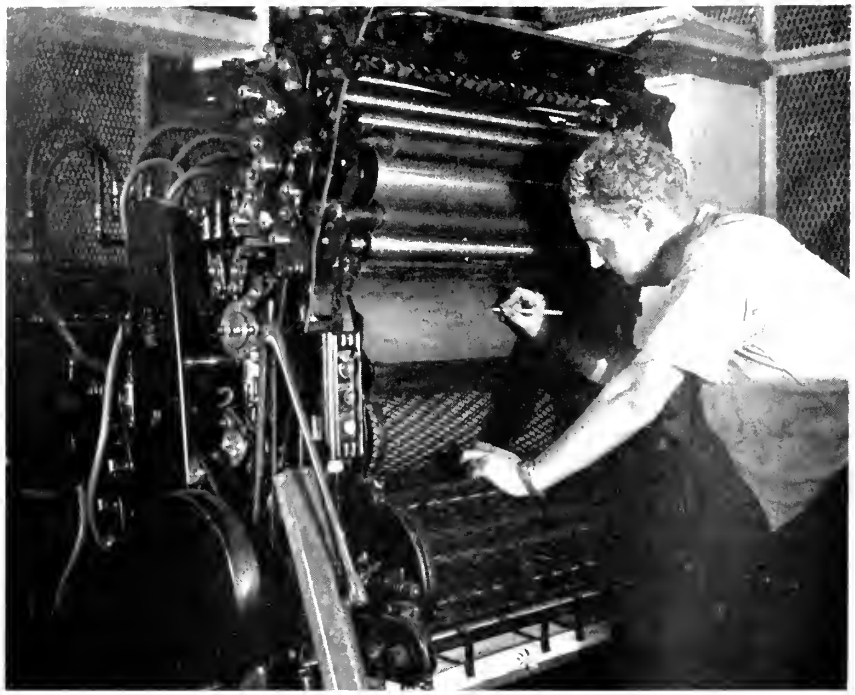
The USS Bowditch, a typical modern survey ship, is a miniature surveying and chart producing plant. This vessel has a length of 236 feet, a beam of 53 feet, and a displacement of 6,500 tons. Powered by Diesel engines, she has a cruising radius of 19,000 nautical miles. On her decks are two 50-foot boats and two 40-foot boats outfitted for sounding and dragging operations, and eight auxiliary boats ranging from 17 to 36 feet in length. It is planned that survey ships will in the future carry a helicopter on their decks and thus be able to do their own aerial photographic work. Bowditch provides not only space for storing surveying instruments, beacons, towers, lumber, cement, canvas, and signal materials, but also drafting rooms, printing presses, storage for chart paper, and a huge camera. This ship not only made original surveys during the war, but also constructed and printed charts which it delivered immediately to the fleet. Three Diesel engine auxiliary vessels, 100-feet long, with a 23-foot beam, and with a cruising radius of 4,500 miles, complete this surveying unit. Bowditch, with her auxiliary vessels, can stay for a period of nine to ten months away from her base.

During the war, the job of the survey ships was not only to take soundings and to chart and find safe anchorages in enemy waters, but also to make anchorages by blasting out coral heads, dragging channels, and by establishing or repairing aids to navigation. They acquired tidal information for the amphibious forces, making it possible for LST's to go over a reef at high tide and to unload when automatically beached within the reef at low tide. Before the Seabeas were organized, survey parties even built coral piers for landing forces.

Under Fire

These ships generally travelled with the Fleet in wartime, but in many instances they went into enemy waters alone with only a few small guns for protection. At Empress Augusta Bay, one survey ship went to work under fire and in less than thirty-six hours had turned off its presses, ready for Fleet distribution, serviceable charts of the harbor, its reefs, shoals, and docking facilities.

Using a stereoscope on an aerial photographic print, tracing the shoreline and topographic contours.



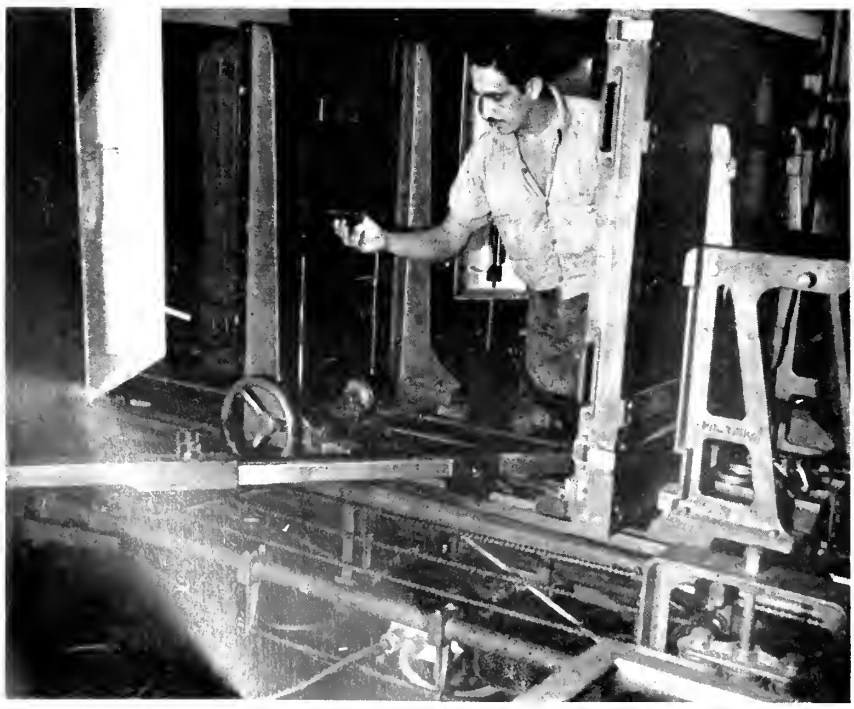
Correcting the zinc plates on the Harris offset press (lithographic) aboard a survey ship. The larger survey ships are now equipped to publish charts in the field. Chart size 17 x 22.

One survey party landed on an island, not knowing the Japs were there; they took their soundings and departed. The next day, the Marines landed.

USS Sumner, during the war, charted fifty islands, accomplishing this record in spite of the fact that she was under enemy attack forty times and led in one invasion. The men often went ashore almost as quickly as the Marines, and started baseline measurements.

The charts produced aboard survey vessels were usually large-scale harbor charts showing in detail, soundings, obstructions, reefs, and anchorages. Sailing directions were printed on the charts. These charts were the first ever published aboard ship. They reduced chart production time from a peacetime average of nine months for surveying and two years (at the Hydrographic Office) for construction and printing, to an average overall time aboard the survey ships of six weeks. Distribution numbered several thousand copies of each chart. Field charts were sent immediately to the Hydrographic Office for re-drafting and reprinting for general issue to the fleet.

Setting the lens of the camera aboard the largest survey ship in the world.



The Hydrographic Office conducts a training program for both officers and men for duty aboard survey ships. Officers are chiefly graduate civil engineers and others have some valuable technical experience as, for instance, draftsmen or lithographers.

Chart Construction

In gearing itself to supply wartime needs, the Chart Construction Division of the Hydrographic Office adopted a number of new methods which virtually put it on a production line basis. The slower method of engraving charts on copper was reserved only for a few original charts. For the mass of wartime charts, the much faster Duco-coated zinc plate method was used and will continue to be used for most Hydrographic charts. This "Duco" method was originated at Hydro in 1938 and utilizes fast photographic methods and zinc plates. The charts are printed in four colors on lithographic presses after having been compiled, constructed, and prepared on zinc Duco plates. Two of the colors, magenta and gray, replaced the buff and orange tints formerly used on Hydrographic charts because these latter became indistinguishable under the red lights used on blacked-out ships.

Another new and most important method used in the construction of wartime charts was photogrammetry. Thousands of pictures were made of areas which we planned to attack. They were rushed to the Hydrographic Office, where they were studied under stereoptican instruments while topography, enemy installations, and other valuable information were outlined on each picture. Then the pictures were arranged in correct sequence on a large table, and the important facts shown on each picture were correctly placed and outlined on charts. The chart of Iwo Jima, for example, was constructed entirely from aerial photographs taken while the Japs still held it. The pictures were flown to Wash-

This beacon at one end of base line is placed on a sandy spit. In order to secure wire guys in sand, "dead men" are buried about three or four feet deep where necessary.

ington, and from them Hydro workers compiled a chart which was flown back for actual bombardment and invasion. It is interesting to note that photographs were taken also from the periscopes of submarines.

Two most important sources of information for chart construction, in addition to photographs, were Hydrographic Office survey ships, whose work is discussed elsewhere, and captured Japanese charts. Large numbers of Japanese charts bound for distribution to the Jap Fleet were captured at Kwajalein. They were of immense value since we had little information on the Japanese-held islands of the Pacific, whereas the Japanese had surveyed them accurately. The Hydrographic Office chart of Truk Atoll was constructed mainly from captured Japanese charts.

Mariners have been sending navigational data to the Hydrographic Office for the past 116 years, and of course, this source of information continued during the war years. Since 1830 more than 10,000,000 reports have been received from ships. These reports include information on soundings, wind and current directions, weather, and floating derelicts. The Hydrographic Office has utilized every piece of this information in compiling and revising both navigational and oceanographic charts and in its many other publications. Charts are corrected and revised at each stage in their construction until the moment they are loaded on trucks for distribution.

An LCM towing a floater into position. A floater is used as a survey signal and as a navigational aid.

Strong, well-placed wire guys are the best insurance against the tripod tipping over in a typhoon.

The speed-up of processes in chart construction is indicated by the following facts. When the Marines landed on Tulagi in the Solomons on August 7, 1942, the survey ships immediately went to work. A series of five field charts of the entire area was developed and rushed by plane to the Hydrographic Office. The charts were combined and worked into a single comprehensive chart. In less than four weeks, the complete charts were in use by the Fleet.

Combat Charts

The most important group of charts published by the Hydrographic Office during the war, to which everything else was made second-

U. S. Navy Hydrographic Office survey vessel, largest survey vessel in the world.

ary, were the combat charts prepared specifically for use in bombardment and invasion of enemy territory in the Pacific Theatre. The combined resources of Army and Navy information were used in their preparation. Aerial photographic coverage and on-the-spot surveying contributed to their exactness.

Charts on five different scales provided information for the approach of ships to an invasion area, offshore bombardment of enemy installations, military ground operations, and air-support of these shore operations. The Navy produced the approach and bombardment charts and prepared aerial target charts. The Army took the responsibility for the charts for military ground operations and other aerial target charts. Basic factual data, conventions, symbols, and military grids were in perfect agreement on all these charts. To the man on the ground, the gunner on a ship, and the bombardier in the air, the charts told identically the same story on a scale best suited to his use. By means of a common point referencing system which consisted of two special grids in addition to the latitude and longitude network, specific targets could be designated with great speed and accuracy, the reference being the same for the land, sea, and air charts.

Aerial photography contributed greatly to the accuracy of these charts. Aerial photographs by the thousands were flown back from future combat areas and studied under a stereoscopic instrument. Topography, enemy positions, and other important targets were indicated. The photos were then placed in their correct positions on a huge table and the information transposed from the photos to its proper position on the charts. Additional information from Hydrographic surveys was incorporated, and the charts were then rushed back to the fleet for use in approaching and bombarding enemy shores. The success of our amphibious operations was due in large part to the complete cooperation and interchange of information on the part of the Army and the Navy, and to faster methods, in the production of these highly accurate charts.

Wave Judith Underdahl inspects Naval Air Pilot Charts and Target Charts, which are part of the first public exhibit of secret and confidential charts in the Library of Congress.

Loran Charts and Tables

Loran, named for Long Range Aid to Navigation by Radio was developed and put into practical use during the war years. It is a most important contribution to navigation because it gives good service in all kinds of weather, it is highly accurate, and enables the navigator to obtain a fix with great speed.

This system employs the principle of measuring the difference in time of receipt of two synchronized radio impulses. From stations on shore, pairs of high-powered transmitters send out continuously signals called "pulses". The signal from one of each pair called the "slave" station is sent out a short time after the signal from the other, or "master" station. The interval between signals is kept constant. Thus, when the navigator synchronizes his receiver with an incoming pair of signals, the receiver automatically measures in millionths of seconds (microseconds) the difference in time between the arrival of the two signals. The points on the earth's surface for which the difference in distance from two given points remains constant fall along a hyperbolic curve which forms a line of position. When readings are obtained from two or more pairs of stations, they give several lines of position and establish a fix.

The direct signals or ground waves from loran transmitters can be picked up for a radius about 700 miles from the transmitting stations. Reflected signals, or skywaves, usually reflected from the ionosphere only at night, are stable enough to be used for readings. They extend the radius to 1,400 miles.

The Hydrographic Office has worked out all the calculations necessary to interpret the loran readings and has published them as 'Loran Tables". For the use of navigators on aircraft, where speed in establishing a fix is a critical factor, the Hydrographic Office has published a series of charts with the loran

Pacific WORLD TRADE
Reg. U. S. Pat. Off.

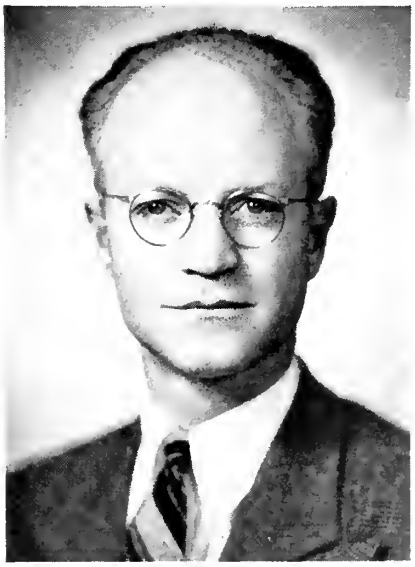
By T. Douglas MacMullen

The Present Argentine Trade Situation

By Elmer George Davis
Pacific Coast Manager, Argentine
Trade Promotion Corporation

While there was a shortage of consumer goods of all kinds in this country during the war, many Argentine manufacturers found ready markets for such items as candy, woolen piece goods, kid gloves, alligator handbags and wallets, floor coverings, wines and spirits, and various miscellaneous manufactured products. In addition, there was an increased demand for many of Argentina's raw materials, to meet the needs of United States industry and agriculture. Included in this second group were such commodities as fish oils, feedstuffs, fertilizers, hides, vegetable fibres, corn glucose, wool, tanning extract, and certain strategic minerals.

For many years prior to the Second World War, Argentina had an unfavorable trade balance with the United States, owing to the fact that she was unable to sell enough of her pastoral and agricultural products to this country to offset her purchases of electrical goods, automobiles, trucks, agricultural machinery, chemicals, office equipment, and other commodities that she bought from the United States. To some extent she was able to meet this unfavorable trade situation by multilateral trade arrangements by means of which she could export her products to and get dollar exchange from other countries that had favorable trade balances with the United States. However, after the outbreak of the Second World War she lost her European markets with the result that ways and means had to be found to increase her trade with the United States and other Latin American countries to make up for her losses.



E. GEORGE DAVIS

As a result of the war and its effects on Argentina's normal trade, impetus was given to the development of her own domestic manufacturing industries, whereby many of the consumer goods normally imported from Europe and the United States could be produced within the country. This was handicapped somewhat during the war owing to the lack of a source of capital goods, as for instance machine tools, since England and the United States had both gone on a war economy. Nevertheless, with what machinery she was able to buy from abroad plus a certain amount that could be produced at home, existing industries were expanded and certain new industries came into being. Included in this group were textiles, petroleum, clothing, footwear, leather goods, prepared foodstuffs, chemicals, pharmaceuticals, and others. Today in

If we increase the standards of living of dependent peoples, we will indirectly be assisting our own peoples because export markets will expand with the expansion of consumption levels.—Evatt of Australia.

Argentina there are industries capable of producing a large portion of the consumer goods used in the daily living of the average Argentine family which has been of considerable aid in preventing the inflationary extremes that have characterized the wartime economies of most of the other Latin American countries.

Because of the abnormal wartime demand for such commodities as meats, meat products, dairy products, fresh fruit and vegetables, tanning extract, hides and leather, wool, cereals, and various miscellaneous manufactured goods, both for domestic consumption and for export, Argentine industry and agriculture have prospered. Being unable to get delivery of many of the needed capital goods during the war, dollar and sterling balances have accumulated in American and British banks, and today Argentina is in a favorable financial position for the purchases that she wants and expects to make in ever-increasing quantities from the United States and elsewhere. However, that does not mean that there is sufficient dollar exchange available to Argentina to purchase all of the capital goods and consumer goods that she needs from this country nor that the Argentine government will allow importers to buy indiscriminately from abroad. Obviously, heavy capital equipment runs into considerable money and purchases of any quantity of such items as locomotives, oil refineries, trucks and tractors from the United States will quickly consume considerable dollar exchange, and for this reason it is necessary to maintain her exports to this country at high levels. Therefore, the Argentine Government may find it advisable to control the buying and selling of foreign exchange for a while so as to insure its use for the purchase of those commodities that are considered necessary to the national economy and public welfare of Argentina, before allowing it to become exhausted in the purchase of luxury goods. If, on the other hand, ways can be found to increase Argentina's exports to this country, particularly in the field of the so-called "non-regular" products, there will continue to be enough foreign exchange available for the importation of non-essential commodities as well as needed capital goods.

At the moment there are certain difficulties, both temporary and permanent, that will have to be over-

come here on the Pacific coast, before we can expect to see any great volume of trade between Argentina and the West Coast. In the first place, many of the products produced in Argentina are also produced in the Western part of the United States. For that reason, both imports and exports of those commodities will be governed largely by such factors as availability, price, quality, and demand. For instance, although dairy products are produced in this area, if the Argentina products are able to compete in this market, in spite of the tariff and some consumer preference for goods that are "Made in the U.S.A.", then there will be some imports into this market. During the war such Argentine products as chocolate coatings, corn glucose, leather goods, woolen piece goods, feedstuffs and fertilizers, although produced in this area, found a ready market here because of the great demand and shortage of those commodities. What the future demand will be for those as well as such items as casein, linseed, corn and protein feeds, will depend largely on future industrial development in this region, but as it now looks, there is bound to be a market on the Pacific Coast for commodities of this type for many years to come.

Because of the great population increase on the West Coast in recent years, if full employment and prosperity can be maintained, this area will no doubt continue to be a large consuming center for many manufactured goods and prepared foodstuffs from Argentina, such as alligator handbags and wallets, kid gloves, woolen piece goods, candy and various other miscellaneous items. The market for these commodities will undoubtedly continue to grow provided qualities can be maintained and improved and prices can be lowered through more efficient and economical production methods in Argentina. Ability to sell many Argentine manufactured goods and prepared foodstuffs in other markets during the war, where there was greater inflation and hence higher prices being paid, tended to retard adoption of more efficient production methods, which will be necessary in order to compete when conditions return to normal and competition sets in.

Right now while the people of many countries of Europe and the Far East are facing starvation, foodstuffs, seeds and fertilizers from Argentina are in great demand. This, in turn, has caused prices of such commodities as wheat, corn, and meat to rise in Argentina, but this situation will no doubt last only for a comparatively short period of time, until the world supply and demand for foodstuffs becomes more evenly balanced. In the meantime, United Nations relief programs and purchasing agreements may necessitate the continuation for a while of certain controls on the distribution of the world supply of foodstuffs. At present, under the program of the Combined Food Board, large quantities of Argentina's foodstuffs are being purchased and shipped to the famine areas, either through government or private channels. This is over and above those amounts being reserved for her own use or for export to neighboring South American countries, such as Brazil, who in turn ships coffee, cotton and minerals to Argentina.

Because of Argentina's comparatively high living standards and industrial development, she will always be a good market for American manufactured goods, particularly those products that are not produced in Argentina at all or else in insufficient quantities to meet her needs. Included in this category are automobiles, trucks, office machinery, lumber, industrial chemicals, agricultural machinery, mining and petroleum, equipment, transportation equipment, machine tools, electrical goods, newsprint and many others.

There are excellent possibilities for greater expansion in the exportation of off-season agricultural commodities including fresh fruits and vegetables, which Argentina also produces at different seasons of the year and ships to this country. Trade in these latter commodities between the two countries will enable the people of both nations to enjoy fresh fruit at reasonable prices the year around, and will provide tonnage for merchant ships with refrigeration facilities. The same could apply to commodities like frozen poultry, dairy products, and other perishable items.

Although the West Coast has heretofore found it difficult to compete effectively with the East Coast in the exportation of heavy machinery and other manufactured goods to Argentina, with greater industrial development in the West and equalized freight rates between West Coast ports and Argentine ports, many commodities from Pacific Coast factories should find their way into the Argentine market. Much will depend, of course, on the willingness of West Coast firms to acquire the "know how" of selling to that country. In order to do that, local firms ought to acquaint themselves with the Argentine market to the extent that they have the markets in the Far East and South Pacific. They should employ travelling representatives and office personnel who not only speak, read and write Spanish fluently, but have, through experience and study, acquired a knowledge of the problems of trading with Argentina and other Latin American markets.

Many people who have not taken the trouble to study trade figures carefully are of the mistaken opinion that the United States enjoys a greater amount of trade with countries that have not advanced industrially and produce raw materials primarily, as for instance, the tropical countries of Latin America. As a matter of fact, this country normally carries on more two-way trade with the more economically-advanced countries, like Canada, Australia, England, France and Sweden. Therefore, because of Argentina's economic development, which has progressed far beyond that of most of her Latin American sister republics, instead of that constituting a competitive menace to United States industry and agriculture, there is every reason to believe that this country will enjoy a larger over-all volume of trade with that country in the years to come than before the war.

While Argentina's tariff program might reduce United States exports of certain products to that country, there will undoubtedly be a greater demand for other types of products. It is an established fact that the best markets for United States exports are those countries with a comparatively high standard of living, which the people of Argentina enjoy, and for that reason, the West Coast has every reason to look forward to future increase in trade with that country.

Selling Machinery in Mexico

By Ralph H. Linderman

Vice President and Manager
Export Division, Perfecald International

In connection with making a market analysis on machinery sales in Mexico, we soon learned that the equipment needed was primarily the same as in our domestic market, and as a consequence we divided our possible prospective markets into the following three major classifications:

I—AGRICULTURAL
II—INDUSTRIAL
III—GOVT. PURCHASES
a) Federal
b) State
c) City

Carrying this analysis a little further, and first considering agriculture, it is interesting to note that one of the contributing factors for this is that the same general type of farm products are raised in Mexico as here in the South West. Consequently, it was not necessary for us to make a great many changes in our product to successfully satisfy the demand of the Mexican market. Likewise, our analysis showed that it would not be necessary for us to change our product to meet the requirements of Industrial and Government markets.

No doubt in your own analysis you will find the same condition true for your products, although this may change, depending on the type of equipment you are manufacturing or selling. We also soon learned that sales were generally made in exactly the same manner as here; that is, through outlets in the farming centers or in industrial centers or anywhere else where a market for our products exists.

Having completed the survey and analysis of the Mexican market, the next important question was: How are you going to sell the market—by direct or indirect methods? That is, have your own export department or sell your product through local export commission agent or merchant who have established outlets in Mexico?

Our company decided to sell direct by organizing our own Export Department, through which we have established distributors, dealers and agents in the key districts for the sale of our product which is an engineered article.

Should you decide to build your own Export Department, you must be prepared to spend a certain amount of money, perhaps more so than if you were entering a new sales territory in the United States. Your domestic sales manager through your established sales organization would take care of creating a new market for your product locally. However, in order to handle your Mexico market efficiently, you must have a competent Export Manager who understands the Latin American psychology and is prepared to sell accordingly.

From our own observation, not only can pumping equipment be sold through this method, but there are many other types of machinery sold this way, even though at the start it may be slightly more expensive than operating through an export merchant or commission house. Many times the sale of machinery or equipment such as our own can be sold through an export merchant or commission house. In fact, we sell part of our equipment, that is, our packaged items using this method. The export merchant or commission house in turn selling either direct to the ultimate consumer in Mexico or to their agent, as the case may be.

The various advantages and disadvantages of the different types of export organizations were thoroughly discussed in our previous Foreign you can always change the distributors or dealers or agents as the case Trade Clinic and for that reason I will not attempt to enumerate them at this time but merely mention again the highlights.

Should you feel from your market analysis that there is not sufficient volume of business available for your product to pay for your own export department within a reasonable period of time, then engage the service of a local export organization. Be sure of one which is thoroughly equipped with the necessary contacts in Mexico and which will handle your account on a retainer fee or commission. This will immediately place your product on a more or less pay as you go basis—that is, no expenses unless sales are made.

Having made your choice to sell through the indirect method, you should check just as carefully on the export merchant or commission house through which you have decided to handle your product as you would on any other outlet in Mexico. In fact, it is my firm conviction that you should check even more carefully as you will be depending upon this export commission house or merchant for all of your sales in the Mexican market you are attempting to reach. If you are selling direct through your own Export Department, you may have one or two poor distributors, but other distributors may be outstanding. Likewise, demands. Do not misunderstand me that from these remarks I am not in favor of the export merchant, because many American specialties and other iron and steel products, particularly of the smaller size, such as hardware items, can and are successfully sold through export commission houses or merchants. On many items in the machinery field, let us use as an example electrical appliances, pumps, business machines and similar commodities, you must take into consideration the need in the future for adequate service and technical facilities of the equipment. In our own particular product, pumping equipment, this was one of the deciding factors that lead us to the organization of our own Export Department through which we established distributors and dealers and agents in the particular location where a demand for our product existed.

The distributor or dealer trained through personal contact to service and repair our equipment. In many items, and again using hardware as

an example, the service factor would not be a contributing point as to what type of method you use in selling the Mexican market.

I believe that at this time I should cite the methods of firms like International Harvester Co., Allis Chalmers, Caterpillar Tractor Co. and others who realizing the importance of their foreign markets select young men from various colleges whom they have determined to be temperamentally fitted for foreign selling. These young men are taken into their organization where they spend two to six years learning the manufacturing, operation, servicing and selling of all of the company's products. During this time these men get a thorough practical knowledge, both from instruction and experience in the United States, so that when they are sent abroad as traveling representatives in the nature of sales engineers, they can, for example, repair a binder or Caterpillar tractor, or seeder in Sonora or in any other place where the equipment is operating. It is quite obvious that men as completely equipped as these will assure the success of the firm's foreign selling at all times. I know of another company who after having selected a representative in the foreign country brings the person to his own shop and office and gives a complete picture of the company's policy and ideas as to the best way to service and sell the product. Our own company has our distributors visit our factory as frequently as possible to keep up to date on new ideas and sales methods. This makes the representative much more efficient and likewise maintains his selling enthusiasm.

Advertising

Regardless of the method of selling used in Mexico, you should set up an advertising appropriation. Depending on your product, decide whether you will use radio, newspaper, international magazines, etc. Again, our Foreign Trade Clinic has given you details on this subject and I am only mentioning it in passing. But by all means **use it.** It is as successful in Mexico as here in the United States.

Last but not least by any means, I think that we should now say a word about financing the sale or the extension of credit. Again this subject has been covered in detail in previous Clinic Meetings which I hope you have read in the published booklet which has been sent to you by the Chamber of Commerce.

Those companies maintaining their own export department and selling through established dealers and distributors in Mexico receive payment from the distributor or dealer as the goods are shipped. The method of payment from the companies' distributors or agents may be either Sight Draft Bill of Lading, Establishment of Irrevocable Letter of Credit or an open book account, depending entirely upon the credit rating of the distributor or agent.

On sales made through an export organization in this country, the manufacturer receives payment in the United States. Most export commission houses or merchants are in a position to finance their own sales, and in this method the manufacturer is assured of payment before shipment leaves the country. A great many exporters have followed the practice of asking for cash with the order or the establishment of an Irrevocable Letter of Credit payable upon completion of shipment. In depression years, when business was hard to get, our exporters, in this country found that their competition was mainly in regard to credit terms, as the European merchants sold on open account or on Sight Draft basis and in many cases extended credit for one or two years. A large amount of American export business was lost in those years because of the insistence of cash or Letter of Credit.

There are good reliable financially responsible outlets in Mexico that are entirely deserving of credit. In the sale of machinery such as our own products, we have found it necessary to use all three types of methods. It is the function of our Export Department to work in close conjunction with our Credit Department. Each sale made through a new distributor or direct to the consumer on whom we do not have credit information a check is always made by our Credit Department through various channels which have been described in previous Clinic Meetings. The terms extended to the customer or new distributor depend entirely upon his credit rating. In the case of our established distributors or dealers or agents, an up to date financial report is maintained at all times. It is a prerequisite that they furnish us with at least two financial statements per year and on demand if there is any feeling on the part of the Export Department or Credit Department that an up to the minute report is necessary.

May I suggest that on checking

John E. Cushing, president of American-Hawaiian Steamship Co., addressing the Foreign Trade Association of the San Francisco Chamber of Commerce. His address appears elsewhere in this issue. In the photo, left to right: Louis Lundborg, general manager San Francisco Chamber of Commerce; John E. Cushing; William L. Montgomery, president Foreign Trade Association, and manager, San Francisco Office, China-America Council of Commerce and Industry.

the financial responsibility of any Mexican firm you check with the other American firms who have a credit history with the firm. Let us suppose that your product is of the so-called individually engineered or tailored to fit the particular job and as a consequence can not be resold or entered into stock to be used with some other order. Under these circumstances it is obvious that such an item must be sold under some method of complete payment before shipment or at least in some manner that you will not sustain loss in case of non-acceptance by the customer. Again, this method of payment must be tempered by what competition is allowing, likewise the familiarity with the customer.

Many American manufacturers of machinery and equipment are now represented in Mexico in some particular form or other. I believe that the majority of them are represented by distributors, dealers, agents or export commission houses or merchants, with a very few following Remington Rand who have their own subsidiary.

To some extent the Mexican market for machinery and equipment is limited because of low purchasing power. Our survey and past experience shows us that population figures may mean very little. In other words, it is entirely possible that your product may not find its best market where the greatest population centers are.

Considering markets versus population, do not overlook that the Mexican Federal Government, the various State Governments as well as many of the municipalities are today one of the biggest outlets for American machinery and specialties. Very definitely your plan of representation for selling in Mexico should include these Government markets. Many outlets in Mexico make a specialty of working with the various Federal, State and municipal government agencies.

In summary, it is no more difficult to do business in Mexico than it is in the United States if you exercise the same preparation and judgment that you do in business here. Just a word of caution—don't rush in blindly—study the market and regardless of method of selling used, be sure it fits the Mexican psychology. The net returns may be a little slower in showing, but it is a worthwhile and profitable market.

Ships For Export

Commodore E. E. Brady, Jr., of the United States Navy, who is technical advisor to the Brazilian Merchant Marine Commission, recently visited The Ingalls Shipbuilding Corporation yards at Pascagoula, Miss. He is shown with Lieutenant Commander Moacyr Rodrigues de Costa, one of the Brazilian supervisors, inspecting inner-bottom sections which are being prepared for the 14 streamlined cargo vessels that Brazil ordered for its government-owned Lloyd Brasileiro steamship line.

Argentina Freed of Trade Restrictions

The way has been paved for resumption of normal trade with Argentina by removal of that nation from the list of countries to which special restrictive export regulations apply, it was announced by the Office of International Trade, Department of Commerce.

General license privileges which enable exporters to ship freely to most countries U. S. commodities that are not in short supply, are now extended to include Argentina.

Only countries remaining on the restricted list are Spain, and its possessions, the possessions of Germany and Japan, and Andorra, Austria, Bulgaria, Hungary, and Romania. No private trade whatsoever is permitted with Germany and Japan.

Loomis Appointed to World Trade Staff

Appointment of William B. Loomis to the staff of the World Trade Department of the San Francisco Chamber of Commerce is announced by Louis B. Lundborg, general manager of the Chamber.

"Promotion of the Bay Area as a leading international trade center has become a major objective of the Chamber, necessitating the expansion of the Chamber's World Trade Department to handle the additional load of trade promotion activities we have undertaken," Lundborg said.

"Addition of Loomis to the staff will help materially to round out our ability to do a constructive job in the important field of world trade development."

Loomis is a graduate of Iowa State

William B. Loomis

College where he majored in mechanical engineering. Upon graduation he joined the export department of the Gates Rubber Company in Denver where his work was devoted to developing sales of industrial rubber products in the Far East, Australia, New Zealand and the west coast of South America. While associated with this company he helped to establish representatives abroad, to supervise credits and billings and create advertising suitable for foreign markets.

In 1940, while connected with the Gates firm, he joined with four associates in organizing their own export house and export sales agency.

With the outbreak of war Loomis left the company and came to San Francisco as an engineer for the Moore Dry Dock Company. In January 1943 he joined Pan American Airways as a flight engineer in the Pacific area, where he served until joining the staff of the Chamber's World Trade Department.

Charles Kendrick, president, Schlage Lock Company, and vice chairman, San Francisco Bay Regional Board, China-America Council of Commerce and Industry. His Excellency Dr. Wei Tao-Ming, Chinese Ambassador to the United States. Photographed at Annual Meeting, April 16, 1946, of China-America Council of Commerce and Industry at Hotel Waldorf-Astoria, New York City.

FINANCING EXPORT SHIPMENTS, is the title of a very helpful export booklet put out by the American National Bank and Trust Company of Chicago. Most of the documentary and banking problems of export shipping are helpfully explained and custom laws treated. This booklet compiled by A M. Strong can be obtained by writing the American National Bank on La Salle St. at Washington, Chicago 90, Ill.

Los Angeles Will Have Far East Trade Commissioner

The Foreign Trade Association of Southern California has appointed George Spillenaar its executive secretary-manager to the newly created post of Commissioner for American-Far Eastern trade promotion. He will visit and develop American interests in the Netherlands East Indies, Singapore and China, in the interests of Southern California industries.

Navy Enlisted Personnel Have Excellent Opportunities For Careers as Officers

Rear Admiral Donald B. Beary, USN, Commandant of the Twelfth Naval District, has pointed out that men of the enlisted ranks of the Navy are an excellent and logical source of commissioned officers. In pointing out the advantages held by enlisted men, the Commandant said, "a former enlisted man understands the reasoning and needs of a sailor. Provided that he has the necessary qualities of leadership he is at a great advantage over an officer commissioned from civilian life in that he is familiar with Navy methods and fleet organization. Many of our outstanding junior officers of today were promoted from the enlisted ranks of the Navy and the Naval Reserve during the recent War. A large number of these officers show promise of going far in the Navy.

"During the war," Admiral Beary continued, "74,185 officers, or 22 per cent of our total peak officer complement, were former enlisted men who had actually served in enlisted status. At the outbreak of hostilities, the greatest potential source of Naval officers was the college-trained group. The policy changed with the increase in the number of qualified enlisted men who had gained the necessary experience. In January, 1942, only about 25 per cent of the commissions were awarded to enlisted men. By July of 1945 more than 50 per cent of the officers appointed came from the enlisted ranks."

During the war there were six ways in which an enlisted man could become an officer. These were: Direct temporary and permanent appointments from the ranks; the "V-5" aviation training program; the "V-7" program for reserve midshipmen; the "V-12" college training program; competitive examination for appointment to the United States Naval Academy.

As the Navy demobilization program rapidly brings the service to its peacetime level, the Navy Department will continue to emphasize opportunity for the enlisted man to attain and advance in commissioned rank. Vice Admiral Lewis E. Denfeld, USN, Chief of Naval Personnel, has announced that many enlisted men will continue to be appointed to the Naval Academy on the basis of competitive examinations. In the class that entered Annapolis in 1945, for example, 66 per cent of the total enrollment of 1142 midshipmen were formerly enlisted personnel of the various services.

The Naval Academy Preparatory School for enlisted men, which prepares candidates for the entrance examinations, will continue to function in that capacity. Last year more than 2000 enlisted candidates attended this school. Admission to the Naval Academy Preparatory School is by competitive examination held annually throughout the Navy. Any enlisted man possessing the required physical, citizenship and age qualifications is eligible to compete for this training.

The Navy Department is formulating a plan to continue the award of direct commissions to qualified enlisted men according to the needs of the service, and the V-5 program continues to accept applications from enlisted men for flight training. In addition a plan has been presented to Congress under which qualified enlisted men may be transferred to civilian colleges for Naval R.O.T.C. training in conjunction with a civilian college education.

Imported Rubber Will Need Synthetic Assistance

Perhaps most important of all the factors which keep John Q. from getting all his tires now is this: The unlimited use of natural rubber will not be possible for two years or more because of difficulty of resuming production in the liberated far eastern areas where most of it is produced. The first precious natural rubber to arrive in America will be reserved for truck tires, and there is a chance that truck tires will be made with 100% natural crude by mid-1946. But since rubber today is a commodity of international relations, and the world supply limited, there may **never** be an all-rubber passenger tire again. At any rate, for a long time, tires will be made with natural rubber in the carcass, and a synthetic tread, the first step being about ten per cent rubber in the carcass areas and the plies in late 1946.

That brings us smack up against the question of synthetic rubber—and right away we encounter another snag that will further delay our friend John Q's ownership of those coveted tires for spring and summer pleasure driving.

When war came there was no time for the rubber industry to design and install new machinery suited to making tires from synthetic rubber, even had materials for such machinery been available. There was not even time to convert for synthetic processing machinery originally designed and intended to handle only natural rubber, even had such conversion been practical. This conversion will doubtless come in due time; but meanwhile, as throughout the war, the rubber industry has been producing "bricks without straw"—has been manufacturing tires from synthetic rubber with machinery the efficiency of which depends upon the use of natural rubber.

At certain steps in the tire making process this machinery, when using synthetic base stocks, must be operated at appreciably slower speeds to prevent scorching the raw material and to avoid damage to the machinery itself. Production of tires from synthetic rubber consequently has been and still is slower than production with natural rubber—so much so that it takes at least one-eighth more time to make a synthetic tire than to make one of its pre-war predecessors. To put it another way, while one crew of rubber workers, using natural rubber, is turning out nine tires, another crew, using synthetic materials, will be turning out only eight tires. And if the missing ninth had John's number on it, John must continue to wait!

At this point, even John is nearly ready to admit that it will take him a little longer than he expected to catch up with some new tires—at least with a full set of them—and that when he does get them they will be certainly and largely synthetic.

These pictures demonstrate the basic difference between natural and synthetic rubber. In the picture at the top of the page are seen two rubber bands. The smaller one is synthetic rubber and the larger one is natural rubber. In the center both rubber bands are being flexed. The picture was taken when both bands were stretched to the extreme. Note that the synthetic band lacks elasticity compared with the natural rubber band. Below, the two bands are returned to their original position. Notice how the synthetic band is now practically the same size as the rubber band. This inability to snap back is a handicap in the manufacture of tires from synthetic rubber.

Foreign Trade Week

That the importance of world trade is becoming generally recognized is evident from the announced programs for Foreign Trade Week throughout the country. As an example, in San Francisco most of the major business and civic organizations are devoting their regular programs during the week of May 20-25 to speakers who will tell of the jobs that foreign trade provides — or **contra,** the number of jobs that would not exist if foreign trade were cut off. Especially significant is the observance in areas remote from the port cities.

It is misleading to assume that the generally accepted 10 per cent of the country's production is the limit of foreign trade importance. To many large industries the export part of the business is a vital part in normal times. For instance, 28 per cent of tractor production goes abroad. That is an important percentage. So is 36 per cent of power-driven metal-working machinery. So is 29 per cent of tobacco, 36 per cent of sulphur, 14 per cent of automobiles, 17 per cent of agricultural implements, 46 per cent of dried fruits and 54 per cent of cotton.

Jobs

But "percents" are cold things. Jobs are otherwise.

When we say 54 per cent of cotton it means half of the men and women employed in cotton growing, half of the ship cargo space, half of the warehouse and pier facilities, half of the financing and insurance.

When we say 46 per cent of the dried fruits it means nearly half of the jobs involved in growing, harvesting, drying, boxing and shipping. On the farm it means the fruit of nearly **every other tree.**

And importing is even more important. An imported item is the **beginning** of an industrial cycle. Jobs in shipping, jobs in hauling by truck or rail, jobs in processing, jobs in wholesaling, jobs in retailing. There is hardly a store in the country that does not handle imported items. And the money we pay for imports is used for buying the products of our factories and farms.

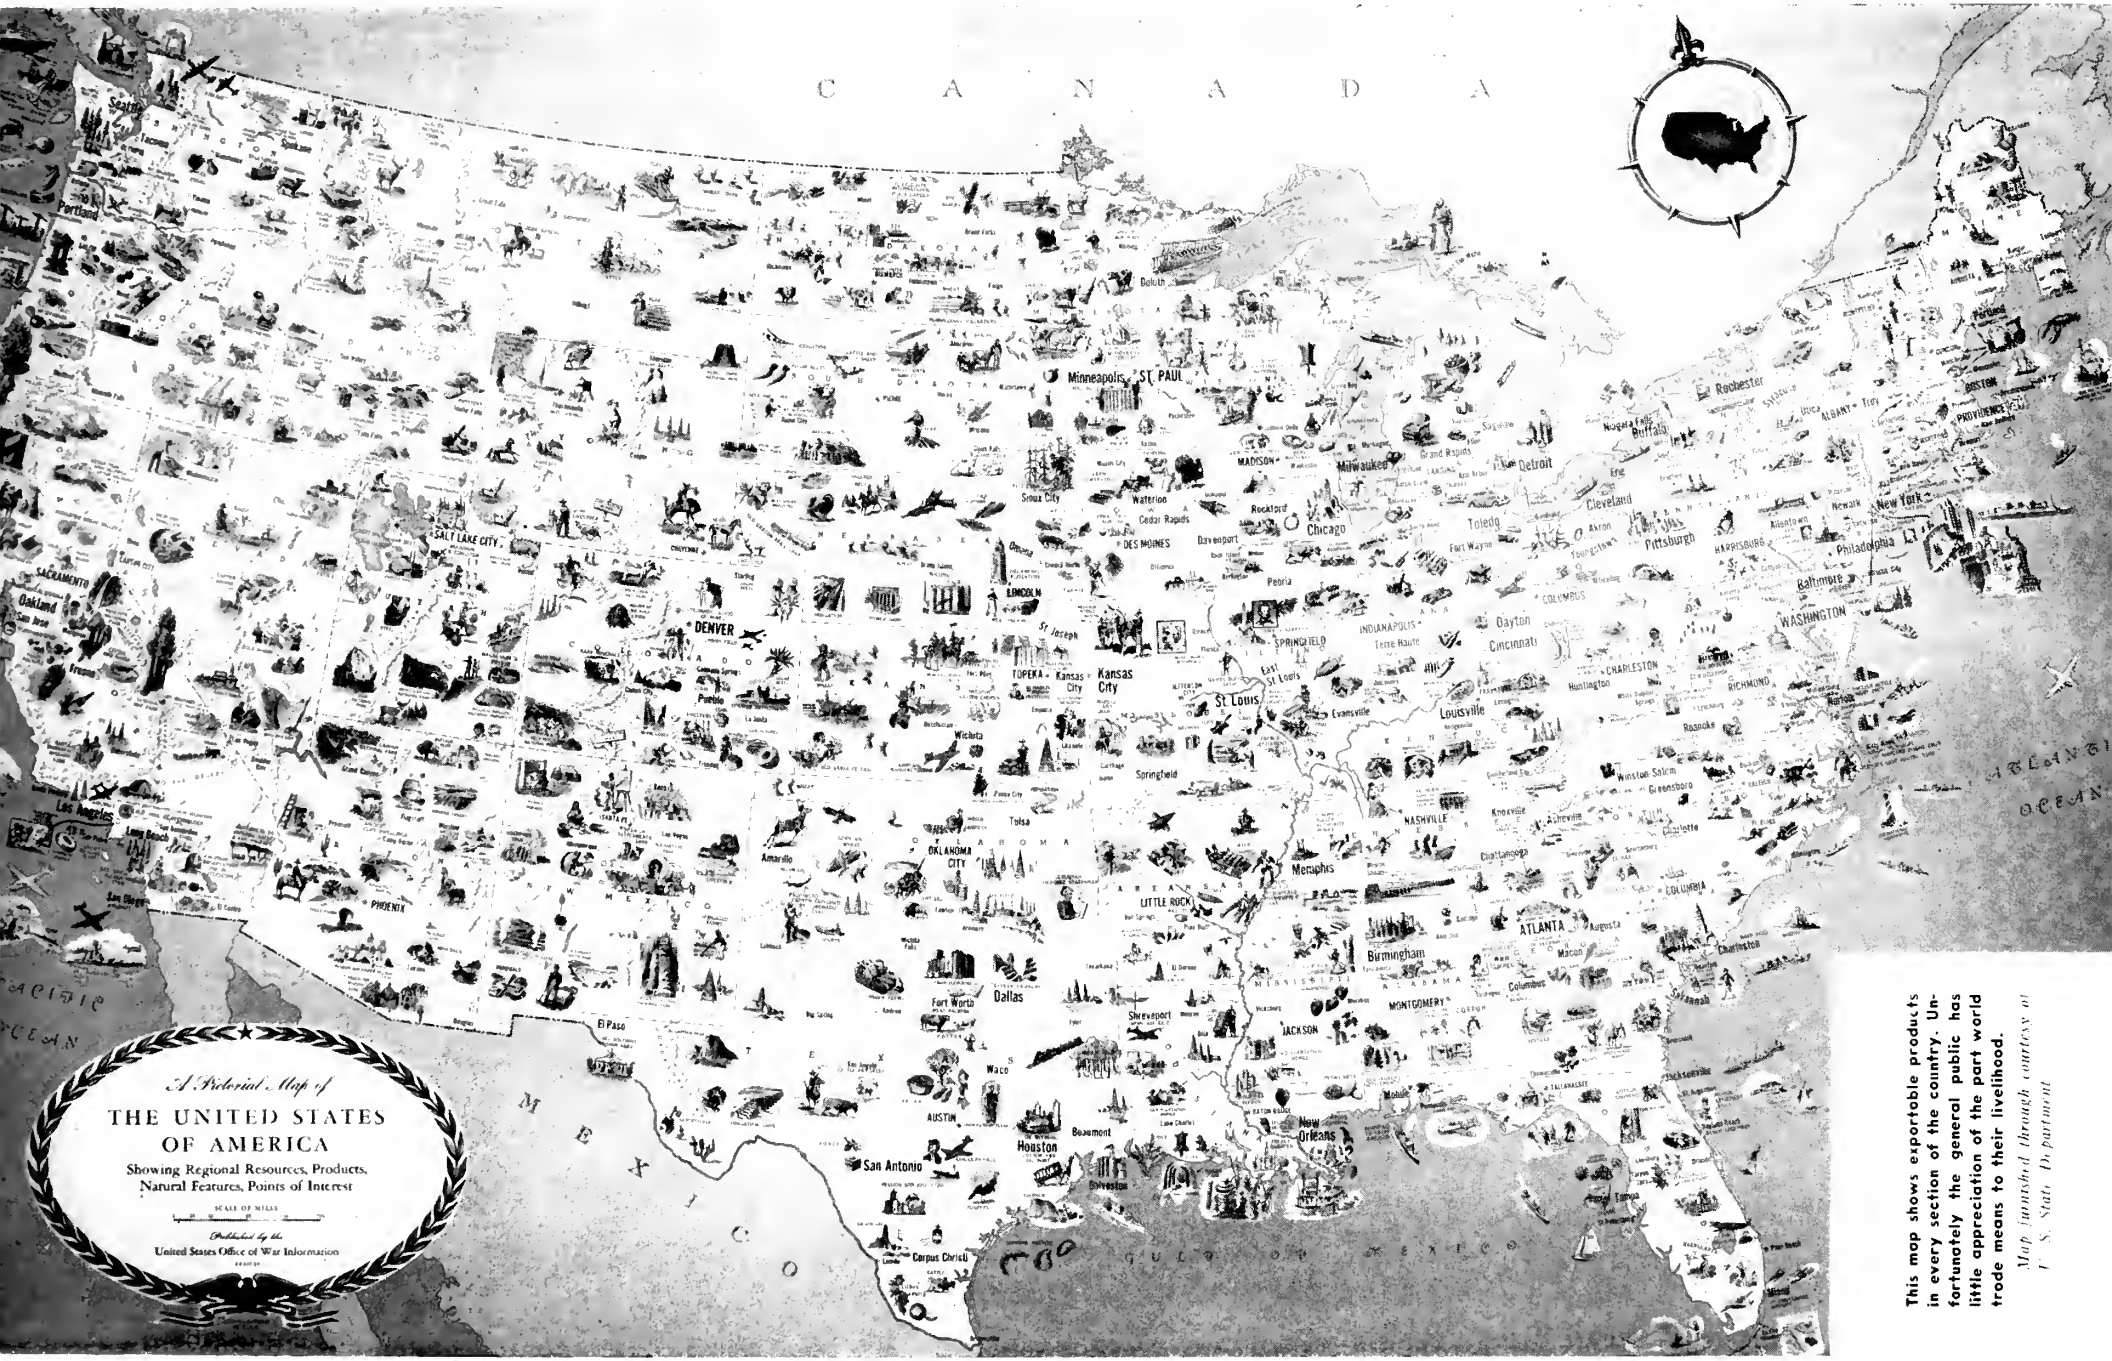
Foreign Trade is important to every one.

Foreign Trade Week is a means for publicizing that importance.

Committee Chairman Arranging Foreign Trade Week in San Francisco

Standing: M. A. Cremer, Marine Exchange; T. Douglas MacMullen, Pacific Marine Review; J. Roger Deas, City Planning Commission; Murray Blanford, General Steamship Co. (Jr. C. of C.); R. V. Winquist, General Steamship Co.; Forrest Brookman, Atkins-Kroll; Ralph Dewey, Marsman Co.; R. E. Dorton, Bank of America.

Seated: Lloyd Mazzera, Bank of America; W. J. Gilstrap, Wells Fargo Bank & Union Trust Co.; W. B. Loomis, S. F. C. of C.; Alvin Eichholz, manager World Trade Department C. of C.; Ray Waterlow, Frazar & Hansen and Chairman of the Committee. The chairman seems to be getting in some good licks for success.



This map shows exportable products in every section of the country. Unfortunately the general public has little appreciation of the part world trade means to their livelihood.

THE SEXTANT

Chapter III (*Continued*)

Errors and Adjustments of the Sextant

Adjustable Errors

1. **First Adjustment.** This adjustment is to make the index mirror perpendicular to the plane of the instrument. To do this, place the index arm about half-way along the arc, hold the sextant horizontally face up with the index mirror close to the observer's eye, and the arc of the instrument away from the observer. Remove the telescope. Now direct the eye obliquely into the lower portion of the index mirror and observe whether the reflected arc as seen in the index mirror to the left, is in the same plane as the arc seen by direct vision close outside the mirror to the right. In other words, are the true and reflected arcs in one continuous straight line? If so, no adjustment is necessary; this is an indication that the index mirror is perpendicular to the plane of the instrument. If, however, the arc appears broken where the images meet, that is, if the line of the reflected arc is seen in the index mirror either higher or lower than the true arc, then the index mirror is not perpendicular to the plane of the instrument, and the ray of light from the observed body is not being reflected to the horizon glass parallel to the plane of the instrument. To remedy this an adjusting screw is placed at the back of the index mirror which may be tightened or loosened so as to bring the true and reflected arcs into one continuous straight line. **THIS FIRST ADJUSTMENT SHOULD ALWAYS BE MADE FIRST.**

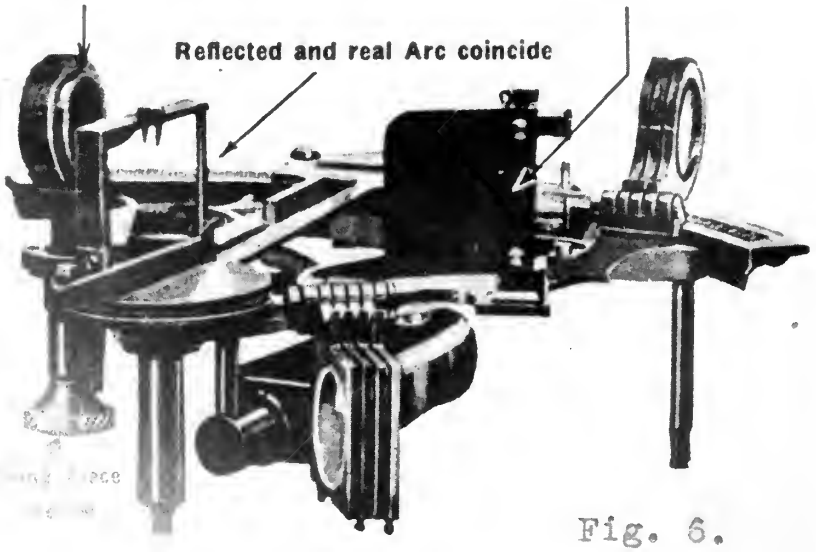

Fig. 6.

Fig. 6 illustrates how the true and reflected arcs form one straight continuous line when the index mirror is perpendicular to the plane of the instrument.

2. **Second Adjustment.** This adjustment is to make the horizon glass perpendicular to the plane of the instrument. To check this use the sea horizon as a reference point. Set the index arm on the sexttant at approximately zero (0°) on the arc; hold the sextant in a vertical position with the right hand and move the index arm slightly until the sea horizon forms one straight continuous line in the horizon glass. Clamp the index arm at this point and rotate the sextant first to the right at an angle of about 20° from the vertical, and to the left at the same angle from the vertical. If, when the sextant is rotated to the right or left from the vertical, the sea horizon remains in one continuous straight line, no adjustment is necessary, as this is an indication that the horizon glass is perpendicular to the plane of the instrument. However, if, when the sextant is rotated from the vertical either to the right or left, the true and reflected horizons "break", the horizon glass is not perpendicular to the plane of the instrument. To remedy this an adjusting screw is placed at the back of the horizon glass which may be tightened or loosened so as to bring the true and reflected horizons into one straight continuous line, regardless of the angle at which the sextant is rotated. **THIS SECOND ADJUSTMENT SHOULD BE MADE NEXT AFTER THE FIRST ADUSTMENT.**

Fig. 7. illustrates how the sea horizon should look in the horizon glass when the horizon glass is perpendicular to the plane of the instrument.

3. **Third Adjustment.** This adjustment is to make the horizon glass parallel to the index mirror, when

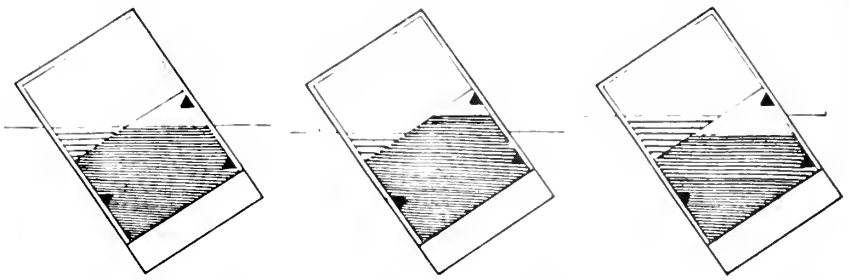
the index mirror arm is set at zero (0°) on the arc. To do this set the index arm exactly at (0°) on the arc and clamp it there. **Check this setting very carefully.** Hold the sextant in a vertical position with the right hand and direct the line of sight at the sea horizon. If the true and reflected horizons appear as one continuous straight line in the horizon glass, no adjustment is necessary, as this is an indication that the horizon glass is parallel to the index mirror. However, if the true and reflected horizons do not appear as a continuous straight line in the horizon glass, the horizon glass is not parallel to the index mirror. To remedy this an adjusting screw is placed on the horizon glass by which means it can be swung about its axis to bring it parallel to the index mirror.

However, it is well to keep in mind that the second and third adjustment screws work on the same mirror—the horizon glass—and that the two motions are dependent one on the other, so that having made the second adjustment correctly, after the third adjustment is made, it may be found on re-checking the second adjustment that it has been thrown a little out of adjustment. Thus, the adjusting screws on the horizon glass may have to be worked on alternatively before both adjustments are completed, and even so it may not be possible to eliminate both errors entirely. The best way to do this is by halving the errors.

For the above reasons—those that in making the third adjustment the second adjustment may be disturbed—it is much better to ignore the third adjustment, unless it is way "out of adjustment" and treat the error as in INDEX ERROR, which will be discussed later on.

THIS THIRD ADJUSTMENT SHOULD BE MADE ONLY AFTER THE FIRST AND SECOND ADJUSTMENTS HAVE BEEN MADE.

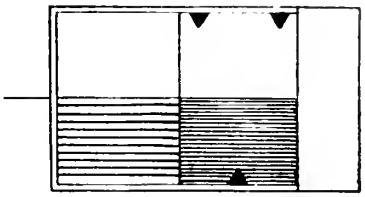
Fig. 8 illustrates how the sea horizon should look in the horizon glass when the horizon glass is parallel to the index mirror, and when it is not.



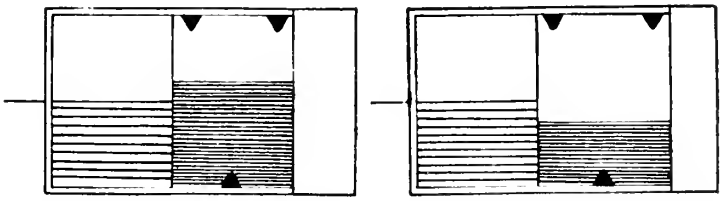
(*a*).—Horizon glass perpendicular to the plane of the instrument

(*b*).—Left edge of horizon glass leans toward the observer

(*c*).—Left edge of horizon glass leans away from the observer



(*a*).—Horizon glass parallel to index glass



(*b*).—Top of horizon glass leans toward the observer

(*c*).—Top of horizon glass leans from the observer

4. **Fourth Adjustment.** This adjustment is to make the line of sight (i. e., the axis of the telescope when "shipped") parallel to the plane of the instrument. To do this select a desk or a stand in the chart room, and place it about 20 feet from the bulkhead. Place the sextant face up on the desk and sight across its arc to the bulkhead. Have someone stand near the bulkhead and place a line on the bulkhead in the same plane as the arc of the sextant. By means of a ruler and a pair of dividers determine the distance from the top of the arc to the center of the telescope. **Move the line on the bulkhead up this distance.** This now becomes a permanent line or point of reference for future use.

Place the star telescope in the sextant with its cross wires parallel to the line established on the bulkhead. Sight through the telescope. If the line on the bulkhead falls exactly midway between the two parallel cross wires in the telescope no adjustment is necessary, as this is an indication that the line of sight is parallel to the plane of the instrument. However, if the line established on the bulkhead falls above or below the cross wires in the telescope it means that the line of sight (i. e., telescope) is not parallel to the plane of the instrument, and that the telescope will have to be tilted up or down (by means of adjusting screws on the telescope bracket) until it is adjusted.

This means of checking the fourth adjustment is the simplest of all for the reason that once the line has been permanently established on the bulkhead it is a very simple matter to check this adjustment.

THIS FOURTH ADJUSTMENT CAN BE MADE AT ANY TIME WITHOUT REFERENCE TO ANY OF THE OTHER THREE ADJUSTMENTS.

Fig. 9 illustrates how the line on bulkhead should look when viewed through the star telescope when the line of sight is parallel to the plane of the instrument, and when it is not.

(a) Telescope parallel to plane of Instrument. (b) Telescope tilted downward. (c) Telescope tilted upward.

Correction of Unsatisfactory Brush Performance

Part II

Commutator Brushes Sources Of Sparking

Sparking is so frequently the source of other operating difficulties that it is often considered a primary source of trouble. Yet sparking is only the result of some other primary fault. Sometimes the primary cause cannot be removed; for example, the necessity for operating a non-interpole machine in both directions. In such cases complete elimination of sparking may not be possible. In a majority of cases, however, the primary cause of sparking is something that can be corrected if the case is properly diagnosed and the underlying fault determined.

The source of sparking may be associated with the nature of the service the machine performs or with surrounding conditions. Operating practice, machine adjustment, mechanical or electrical faults in the machine, brush angle, and design characteristics are other factors which affect commutation.

Load or Service Conditions

Heavy overloads often result in sparking, particularly when they result in magnetic saturation of the interpoles and incomplete compensation of the voltages induced in the armature coils during commutation. Very rapid load changes have similar effect due to the lag of the accompanying change in field strength. Where such load conditions are inherent in the operating cycle, and cannot be corrected, a brush grade of high carrying capacity and the best possible commutating properties should be selected. If sparking cannot be prevented, the use of a canvas wiper, will greatly assist in maintaining satisfactory machine performance. In some cases it may prove necessary to use a brush grade having some polishing action. Low average current density, previously mentioned as a source of commutator streaking, may also lead to sparking.

Atmospheric contamination has been discussed as a cause of raw or discolored commutator surface which, in turn, may lead to destructive sparking. Humidity also has an influence on commutation. Very low humidity makes it difficult to maintain the oxide film essential to good commutation. Furthermore, the disappearance of the oxide film increases the friction of the brushes and may cause chattering with resultant sparking. Air conditioning or the use of brushes having greater film forming properties are the usual means for correcting such conditions.

Vibration will cause sparking whenever it is of sufficient severity to interfere with the contact of the brushes on the commutator. Loose foundation, pound of engine and poor belt lacing are among the external sources of vibration to which sparking may be traced. Vibration induced by other equipment, bad rail joints or crossings in traction service and like causes, if not subject to correction at the source can sometimes be counteracted by cushioned mounting of the motor or generator affected.

Operation and Adjustment

The maintenance of sparkless commutation requires a certain amount of care on the part of the operator. Any operating practices which unfavorably affect commutation should be discontinued. Unnecessary use of sandpaper and lubrication of the commutator with wax or oil are sources of sparking which, fortunately, are encountered with much less frequency than in former years. Generators which give no trouble when operated alone may show sparking when operated in parallel unless properly equalized. Methods used to correct difficulties in parallel operation include adjustment of the series field strength, elimination of inequalities in angular velocity and, sometimes, slight shifting of the brush position.

The condition, spacing and alignment of brush holders, equalization of air gaps and pole face spacing, staggering of brushes to prevent ridging of the commutator, careful seating of brushes to full face when first installed, adjustment of spring tension to a uniform value within the range recommended for the grade in use, and setting of the brushes in the position for best commutation are items which have a marked influence on commutation.

Over- and under-commutation are sources of sparking. They can usually be identified by the contact drop between the brush and commutator at several points across the brush face in the manner there described. To rapid reversal of current in the short circuited coil, a source of sparking, is frequently associated with over- or under-commutation. Over-commutation is corrected by shifting the brushes against the direction of armature rotation or by decreasing the strength or span of the interpole field. Under-commutation is corrected by shifting the brushes in the direction of rotation or by increasing the strength or span of the interpole field. Adjustment of interpoles was discussed in this section last month under "Slot Pitch Marking." Thinner brushes are sometimes used to relieve over-commutation and thicker brushes to correct under-commutation but the use of brushes that are too thin may cause sparking because of the very rapid current reversal resulting.

Sparking which results from chattering or interruption of contact be-

tween brush and commutator can often be eliminated by adjustment of spring tension or by changing the angle at which the brush bears on the commutator. High spring tension may cause high friction, with resultant chattering, while low spring tension allows contact to be disturbed by slight vibration or inequalities of the commutator surface that would not be troublesome at the correct brush pressure.

Machine Defects

Among the mechanical defects in motors and generators which constitute sources of sparking are: worn bearings, resulting in unequal air gaps and non-symmetrical field strength; unequal spacing of pole pieces; loose poles or pole face shoes; inaccurate spacing or alignment of brush holder supports; vibration, either from loose parts or from lack of dynamic balance; eccentric armature or commutator; and any of the defects of commutator surface discussed in earlier paragraphs.

Most common of the electrical faults are probably winding defects, in either field or armature windings, which disturb the symmetrical distribution of magnetic flux or load current. These may take the form of short circuited turns, grounds, open circuits or high resistance connections. Practically every maintenance shop has means for detecting and locating faults of this character. Reversal of polarity on either a main pole or an interpole is not a common fault but, when it occurs, is a source of vicious sparking and should be corrected without delay. Electrical unbalance, even though too slight to be a direct cause of sparking, may induce vibration in the machine from which sparking later develops.

Brush Grade

It is well to point out, that careful consideration should be given to other factors influencing performance, particularly those affecting commutation, before deciding to change the brush grade. Sparking is one of the first indications of an unsatisfactory condition. Since it appears at the brushes there is a tendency to think immediately of changing the brush grade rather than to seek the primary cause of trouble in load or service conditions, operating practices, machine adjustment, or possible mechanical or electrical faults. Only after these items have all been thoroughly checked should change of the brush grade be considered. Both time and expense will be saved if this practice is followed.

When the fact has been established that the wrong grade of brush is being used, the next step is to determine, if possible, its shortcomings for the service to which it is applied. Intelligent selection of a new grade cannot be made on the basis of the single fact that the grade in use sparks. The whole situation must be analyzed, much as a physician diagnoses a case of illness, and the prescription written on the basis of the symptoms observed and knowledge gained from past experience.

With electro-graphitic brushes sparking may be due to the use of a grade having a commutation factor that is too low. The use of a brush with higher contact drop will, in most cases, improve commutation. However, it has been shown that sparking underneath the brush faces is liable to occur when the voltage drop across the contact path appreciably exceeds three volts. Therefore, sparking accompanied by a high resistance glaze on the commutator indicates the need for a brush which will maintain a lighter surface film, possibly a grade with mild polishing action.

The carrying capacity of the grade selected, as given by the manufacturer, should not be less than the current density to be carried. On the other hand, at low average current density, film forming properties rather than carrying capacity should be the major consideration.

Among other factors to be considered are the peripheral speed of the commutator, the angle at which the brush is mounted, whether leading or trailing, and adaptability to the service involved and to the operation on undercut or flush mica commutator, as the case may be. It should be apparent that no fixed rule can be laid down for the selection of a brush grade to correct the unsatisfactory performance experienced with another grade. Facts must be collected, in some cases measurements made, and all factors carefully analyzed in the light of experience. That is the reason it is advisable to enlist the cooperation of the brush manufacturer and obtain the advice of his engineers who have had extensive experience in brush application.

Design Characteristics

There are many details in the design of a motor or generator which have an influence on its commutating properties. Among these are the stiffness of the main field, proportion of pole face span to pole pitch, degree of saturation in various parts of the magnetic circuit, length of gap for both main poles and interpoles, details of armature winding, average and maximum bar to bar voltage, number of armature slots spanned by the interpole flux, duration of the commutation period, brush thickness, peripheral speed of commutator, angular velocity of armature and rigidity of armature shaft. Most of these details are beyond the control of the operator but there are some, such as span of interpole flux, duration of commutation period and thickness of brushes, which can be modified when the need is indicated.

It has been observed on some interpole machines that the span of the interpole flux on the armature does not bear an integral relation to the tooth or slot pitch. Where this is the case the number of armature teeth through which the interpole flux passes varies with the angular position of the armature. This is shown in Figure 3, A and B, where the flux span is one and one-half times the tooth pitch. Such a condition produces a flutter or high frequency variation in the interpole field strength which may prove disturbing to machine performance. By beveling the interpoles at the face the flux span can be made equal to one tooth and the tooth area spanned by the flux will be the same for any armature position, as indicated in Figure 3, C and D. If the interpoles are narrow, beveling the faces may make the commutation period so short that sparking results from too rapid reversal of current in the short circuited coil. In such cases an integral ratio between flux span and tooth pitch can be obtained by increasing the interpole air gap, thus giving the flux greater spread, or by attaching shoes to the interpole faces. If the interpole air gap is increased in any manner other than the removal of non-magnetic shims, it will probably be necessary to adjust the interpole shunt or add turns to the interpole windings to offset the increased reluctance in the magnetic current.

Sources of Excessive Heating

The most frequent cause of excessive heating is overload but there are numerous other conditions which produce excessive temperature in a machine that is

being operated within its rated load capacity. When circumstances make it essential for a machine to be operated at loads in excess of its rated capacity careful attention should be given to all of these other factors. If they are properly taken care of it may be possible to carry substantial overload without dangerous temperatures being reached in any part of the machine. In extreme cases it may prove necessary to supply supplementary ventilation.

Sparking

Sparking raises the temperature of the commutator and, in that sense, is a direct source of overheating. Most sources of sparking, however, are in themselves the direct cause of the accompanying excess temperature. This is particularly true when the sparking results from heavy short circuit current during commutation. Incorrect brush position, unequal brush spacing, faulty interpole adjustment, excessive brush thickness, misalignment of brush holders, unequal air gaps and insufficient voltage drop across the brush contact are among the more common causes of heavy commutation current.

Unbalanced Distribution of Armature Current

Disturbance of the balanced distribution of current in the armature results from any lack of symmetry in the magnetic field, such as that caused by unequal air gaps or pole spacing. Unequal spacing of brushes has a like effect. Open or high resistance connections at the commutator or cross connections, insufficient cross connection and faulty operation in parallel with another machine are other sources of unbalanced current distribution. In addition to overheating the windings which carry more than their normal share of current, unbalanced distribution tends to increase hysteresis and eddy current losses in the armature core.

Winding Faults

Open circuits, short circuits, grounds and high resistance connections, in either field or armature windings, are all potential sources of excess heating. Such faults can usually be located by means available in most maintenance shops.

Friction

Excessive temperature at the commutator is sometimes caused by high friction. This may be due to the use of brushes with high coefficient of friction which are not adapted to the machine to which they are applied. The wedging effect produced by operating brushes in the trailing position at too great an angle from the radial tends to seriously raise the commutator temperature. The condition of the commutator surface has a marked influence on friction. A raw commutator has much higher friction than one with a good oxide film. For this reason care should be taken to protect the commutator from "contact poisons." Low humidity, excessive brush pressure, high ratio of brush area to total commutator area and dirty commutator surface are other sources of undue frictional heat at the commutator.

Ventilation

Since all energy losses within a machine assume the form of heat, it is essential that sufficient ventilation be maintained to remove this heat as rapidly as it is generated. Otherwise, dangerous temperatures will be reached. Ventilating ducts should be kept clean by blowing out frequently and thoroughly. In dusty locations rapid clogging of the ventilating passages is liable to occur and efforts should be made, if possible, to protect the machine from atmospheric dust.

Heating of Individual Brushes

Heating of individual brushes is sometimes indicated by the appearance of glowing or incandescent spots at the brush face or by discoloration of the shunt cable. Accumulation of copper at the brush face, raw streaks on the commutator surface, unequal brush pressure, and loose connection of shunt terminals are among the more common causes of the selective current collection from which this localized heating results. Heating of the commutator has been relieved, in some instances, by using brushes of lower contact drop.

Sources of Brush Noise

Noisy operation of brushes is usually caused by chattering although, in some cases, the frequency of brush movement may be so high and the amount of separation between brush face and commutator so slight that no visible sparking results. On some small, high speed motors with undercut commutators it is possible that an audible tone may be produced merely from the rapid passage of the slots under the brush, without contact between brush and commutator being disturbed. The frequency of slot passage at the brush edge on such motors is on the order of 5,000 per second. In most cases involving marine equipment correction of conditions tending to interrupt the firm contact between brushes and commutator will relieve noisy operation.

Commutator Surface

Practically any faulty condition of the commutator surface will cause chattering and noise. This is usually of relatively low frequency and the sound effect one of rapid vibration rather than a well defined tone. Rough or dirty commutator, high mica or mica fins, high or low bars, burned bars, and flat spots represent the more commonly encountered commutator surface defects producing chattering and noise.

Friction

Chattering caused by high friction usually is of higher frequency than that caused by surface faults and the resulting noise often has a clearly defined tone, sometimes of very high pitch. Low average current density, resulting in loss of oxide film, low humidity, "contact poisons," and brush angle are representative of the conditions which should be looked into when high friction is indicated as the probable source of noisy operation.

Brush Grade

Composition has an influence on quietness or brush operation, some grades being inherently more quiet than others. The harder carbon and carbon-graphite grades are, as might be expected, most susceptible to noisy operation, while graphite brushes, because of their softness, are usually quiet. Electro-graphitic grades are, in general, quiet in operation because of their low coefficient of friction. Should noisy operation be experienced with an electro-graphitic grade of relatively low commutation factor, when the commutator is in good condition and all factors tending to create high friction have been corrected, improvement may be effected by using a grade of higher commutation factor or greater film forming properties. On the other hand, if streaking or a raw commutator surface also appears, the primary source of trouble may be faulty commutation, atmospheric contamination or low average current density. Our June Issue will contain a tabulation of commutation troubles and their probable causes, which will conclude this series on brushes and commutators.

Report on a Boiler Casualty on C-4 Vessel

The boilers on this type of vessel are single pass, cross drum sectional header type equipped with water walls at sides and rear of the furnace, interdeck superheater and overdeck airheater.

The following conditions obtained just prior to this casualty.

1.—Only one boiler had steam pressure and was being used for port load.

2.—Tubes had been blown at 4 day intervals while lying at anchor in port, approximately 1½ months.

3.—Considerable water-contaminated oil had been taken aboard. Estimates given as to amount of water was that approximately 1,300 bbls. of water had been pumped overboard out of the original amount of approximately 5,600 bbls. and still trouble was being experienced with water in the oil to the oil burners.

4.—Fires went out due to water in the oil and could not be relit.

5.—Plant was secured with steam pressure at 250 psi and diesel oil from cold start tank at approximately 40 psi was fed to burners.

6.—D. C. Heater level was low due to stoppage of motor-driven condensate pump when plant was secured—(Note: This vessel is not equipped with a steam-driven condensate pump).

7.—When water went to bottom of gage glass, with 125 psi steam pressure the fires were cut out and reciprocating feed pump started. With 1" of water showing in the gage glass, steam pressure was down to 40 psi.

8.—Diesel oil tank being nearly empty, the settlers were opened providing fuel oil at 118° F to fuel oil service pump equipped with a 10 hp motor, which was run at its slowest speed from the 15 kw emergency diesel generator. The forced-draft blower driven by a 50 hp motor, also was running at its slowest speed from the same power source. When the steam was raised to 125 psi water went out of sight in the gage glass.

During all these operations oil had been sprayed onto the furnace floor because of insufficient pressure on the diesel oil, and insufficient temperature on fuel oil. At this time fires were shut off, oil pump and forced draft blower stopped and air duct damper closed. All these steps took place in order from 9:00 AM till 2:10 PM at which time plant was totally secured with a small fire from unburned oil burning on the furnace floor.

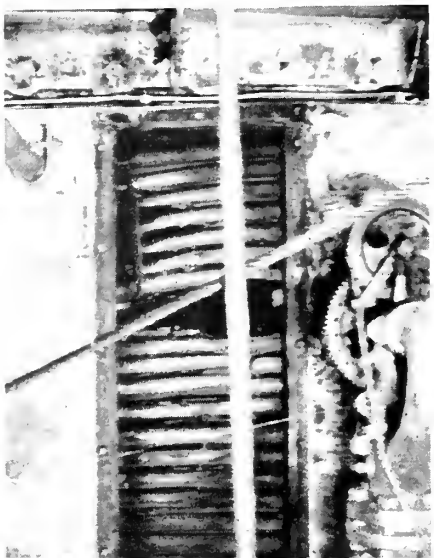
At 5:15 PM the casing adjacent to the air preheater was noticed to be red hot and molten metal was dropping onto the floor of the furnace. Assistance was then asked from the U. S. Navy. The bottom of the air heater casing being red hot, eight foamite fire extinguishers were emptied into the furnace with only temporary effect. The fire continued in the upper parts of the boiler. No attempt was made to use the CO_2 equipment because the Chief Engineer felt this would form a non-combustible atmosphere which would not cool the mass of molten metal below the ignition point of the oil vapor present in the furnace and a furnace explosion could be expected. This was concurred in by the officer in charge of the Navy fire party sent aboard the ship. At approximately 8:00 PM boiler was apparently cooling down. These are the apparent facts as stated.

Conclusion: Diesel oil at approximately 40 psi to burners was insufficient pressure to cause atomization of oil. Carbon and burning oil accumulated on furnace floor causing soot formation throughout the boiler, on all heating surfaces. Some of the lighter fractions of the oil, on striking the hot carbon would be gassified, and proceeding up through the boiler in the form of a vapor would be condensed, especially in the cooler portions of the air heater, thus forming a mixture of light oil-soaked soot. This condition was later aggravated by the use of fuel oil at 118° F. a temperature where normal commercial fuel oil will not burn properly in any mechanical atomizing oil burner. All that remains necessary under these conditions to cause a disastrous fire is for a stray spark to ignite this oil-soot mixture. This apparently happened in this case with results as shown in accompanying photographs.

Top: View looking upwards from boiler furnace, showing burned tube nest. Air heater tubes in distance.

Center: Front wall, showing slag and melted boiler tube metal running down.

Bottom: View of air heater with access door removed, showing tubes burned away.



THE AMERICAN MERCHANT MARINE

(Continued from Page 390)

handling of the problems involved in the reconstruction period upon which we are now entering.

His Majesty's able new Minister of Transport was at pains to tell us in London again and again that with his government, socialization stopped at the sea coast. Coal mines, yes, railroads, yes, banking, maybe, but offshore shipping, never.

Across the channel, however, the French chambers have already made the initial moves toward complete nationalization, and unless the coming elections change the complexion of France's government, it looks as though her merchant marine would be wholly a government affair—at least as far as ownership and profits are concerned—in spite of the desperate resistance of her shipping industry.

The Scandinavian countries are all following one pattern to a greater or lesser degree. There the governments have said to their shipping industries, "We require so and so much by way of imports. You take the full responsibility for seeing that those programs are fulfilled. Beyond that my children, send your ships forth into the world and get every dollar you can lay your hands on." Holland seems to be moving toward a somewhat similar course, but finding it harder to get started.

Japan, Germany and Italy are, of course, no longer in the picture, and the Soviet merchant marine, which is definitely becoming a factor to be reckoned with, represents the extreme of nationalization or, if you prefer, socialization.

Here at home and in Canada, your guess is as good as mine, but happily the present trends seem to head down the British road. I would like to return to our own situation a little later rather than enlarge upon it now.

Beyond all this are two other interesting phenomena to be reckoned with. There is a perfectly proper but nonetheless most complicating desire on the part of numerous other governments to set up shop in the maritime field and to enjoy the luxury of merchant marines under their own flags. The easiest way to enumerate them is negatively. Bolivia, Switzerland and Paraguay may lack the urge, but I would not be too sure even of them. All these nations are talking of ships under their respective flags as real instruments of national policy and not of their flags as corporate disguises or conveniences.

Finally, in a vague and nebulous way, you run across people who are thinking of a future when all merchant shipping will fly one flag and be disposed and directed by one international body to serve the common needs of a united world. It may sound on the fantastic side, but you will most certainly hear more and more of it as time goes on, and many of us here may live to see the day when the school children of the world will be competing for the honor of designing the merchant shipping flag of the United Nations. That body already has made provision for machinery to deal with world shipping problems and not illogically,—since control of the seas has not in the past been one of the lesser factors that go to the breeding of war.

All in all, it does not look as though we were moving toward an era where greater freedom of private shipping would be the rule. On the contrary, the straws in the wind seem to point toward a strengthening of those governmental policies and activities which view shipping as one of the major tools in national and international affairs.

Before I come to what I think all this means to us as shipping people, you may be interested in the attitude of the other leading maritime nations toward our merchant marine, as far as an admittedly hurried observation can piece it together.

First and foremost, for the immediate future they are afraid and consequently suspicious. Our tonnage preponderance is so vast that it overwhelms them to think what we might do with it if we should elect to follow the familiar paths of history, and act tough.

Whenever the subject was mentioned, there was a tendency to play down the security functions of merchant shipping—to say that the idea of its being an essential arm of a great sea power might be outmoded—and to stress the economic functions—with the old familiar refrain, "He who can do it the cheapest should have the job to do." In that connection, there was also the talk of internationalization, which I have previously mentioned.

Even our modest "fifty-fifty" formula was more or less taboo as a subject for discussion. Nobody liked any set formula that savored of percentage divisions of that type. Why, I just do not know.

There was, of course, constant reference to the bareboat charter, of our tonnage to non-citizens, and we can expect all sorts of moves to get that legalized. Obviously, the shipbuilding nations do not want to buy our standardized, war-built ships except as a stopgap against construction programs of their own, and chartering is, of course, a cheaper and more effective stopgap than purchase.

In fairness, its proponents make a strong case. The great bulk of ocean cargoes today are for the relief and rehabilitation of suffering people. Most of the other maritime nations have a surplus of officers and crews. All of them can run ships more cheaply than we can. If we charter to them, the dollars so saved could be spent in the purchase of more goods for relief.

I express only my personal opinion when I say I am opposed to bareboat charter, in spite of the undoubted merit of the arguments in favor of it. I have spoken of the ambitions of the many previously non-maritime governments to create merchant marines of their own. It is hard to see how we could charter to one and refuse another. It does not seem sensible that we should deliberately add another major complication to the confused and difficult shipping situation of today.

Furthermore, our own enlightened self interest seems worthy of occasional consideration. If we embark on any wholesale charter program, what becomes of our officers and crews who would otherwise have manned the ships which did the jobs? What happens to our repair yards and ship service organizations when the chartered ships repair and service abroad? And, after all, the freight rate savings are more or less fictitious since the United States must still carry a large proportion of the movement, and the level of rates must therefore reflect American costs.

For the long pull, I think the other nations do not particularfly fear us as permanent competitors on a large scale, unless our whole world policy should take an aggressive turn. They are confident that their costs will always be lower than ours and that on a lean market they can always underbid us for cargo. They feel, prob-

ably with justification, that our present subsidy policy would fall of its own weight if it were extended to support a greatly increased merchant fleet. Finally, they consider that they have the same substantial advantage which they enjoyed in the 1920's, of individual against standardized construction, which works more and more in their favor as time goes on.

Curiously, they recognize our right to a substantially greater offshore fleet than we have ever had before. They appreciate that we cannot compete without some offsetting form of subsidy, and yet they honestly seem to regard the subsidy provisions of the 1936 act as highly discriminatory and unfair to them. Again I just can not tell you why.

And now, I would like to say a word on what all this may mean to us and to ask you to consider most earnestly two matters which seem to me of real and immediate practical importance.

I am not going to attempt anything by way of crystal gazing. I do not know what our national policy is going to be; what is going to happen to the United Nations; nor in any small particular where we are headed from here.

But in two matters I truly believe we can and should take steps to prepare ourselves for whatever lies ahead. They are difficult steps, but possible of accomplishment because others have long since accomplished them.

Cost factors aside, I believe we can build ships and run ships as efficiently as any of our foreign competitors, with the possible exception of our Scandinavian friends. In liner operation, I think we can more than hold our own when it comes to the refinements of service—either passenger or freight. Our officers and crews have proven over and over again these past few years that in courage, resourcefulness and seamanship they need acknowledge no superiors. Our genius for technical innovation and improvement ranks on the highest level.

Where we are weak, and woefully weak, is in our relations with each other, and equally in our unescapable contacts with our government—which is, after all, composed of men very like ourselves.

Compared to the integrated and highly polished pieces of machinery which are the industry organizations of Britain, Holland and Scandinavia, we are still in the era of sail. Because they are human beings, they cannot be free from internal bickerings and frictions, but sit in meeting with them and you learn what a united front really means. When they talk to their governments, when they collectively bargain with their unions, the voice that speaks is the voice of an industry spelled with a capital I. That sort of thing carries weight and real authority. Better yet, it makes for industry self-respect.

There seems to be some curious inherent quality in us that gives us the urge to take on one of our own gang rather than an outsider. Worse yet, we seemingly prefer to take him on in front of an audience, and the bigger the audience the better. We must, we simply **must,** learn more of the ways of give and take, of looking for common ground and of presenting a united front. If we cannot do it, then for the nation's sake, we had better stand aside and let someone else do it who can.

We suffer again by comparison with our friends from overseas in the matter of relationships with those government departments who together with the industry, mean shipping in the national sense. If you have called yourself a shipping man all your life, you cannot help a little thrill when a man whom you know to be just a plain shipowner stands up before the representatives of eighteen sovereign governments and says, "When I speak, I speak for Norway," or another gentleman of the same ilk casually tosses out, "To that proposal, Sweden says NO." Imagine how far one of us would get trying to play that role for the United States.

Here again, our reactions are inherently different from theirs. In the best American tradition, we damn Washington's every move. We pretend to believe it is peopled solely by some strange race of lotus eaters, who could probably never get jobs elsewhere, certainly never meet a payroll, and who spend their brief working hours devising new projects for the squandering of taxpayers' money. Yet we lean and lean hard on Washington when it suits us to do so.

We really know better than to behave as we often do, but we are in the clutch of habit, and bad habits are notoriously hard to break.

I have been fortunate enough to come to know many of our government shipping people through intimate daily association in the war years. For the most part, they are good run of the mill Americans—conscientious and hard working. While I do not always agree with what they do, I can testify that they generally do it because they think it is right.

They are mindful of the dignity of the United States, and of the solemn oath they have sworn to uphold it. But they are continually harassed by budgetary limitations and entangled in the bureaucratic procedures which are, after all, only the checks and balances of the democracy we have just fought to preserve.

They deserve our support, our cooperation and our respect. We should do more to give it both for their sakes and our own. We and they must learn to pull together as industry and government do abroad or we shall fetch up with a sorry American merchant marine. Again I feel, for the nation's sake, we must change our habits of mind, or let someone do it who can.

Where there's a will, there's a way. Give us the will to a united industry, standing with its government, and the way will open ahead of us on a true course, and steaming full and down.

CYCLOIDAL PROPELLER

(Continued from Page 402)

periodic load changes on the propeller blades and the hull plating, which causes the ship to vibrate. This characteristic is inherent in the screw and cannot be eliminated or modified. The cycloidal blades, however, do not approach or recede from the hull as any point on a blade remains equidistant from the hull. This completely eliminates the vibration producing impulses.

An important mechanical feature of the cycloidal propeller is the accessibility of its blades without drydocking the ship. A blade removal or replacement while the ship is afloat can readily be accomplished. Thus, if a blade or blades are damaged by flotsam or beaching, they may readily be replaced by spares. It is important to note that a cycloidal ship is operative in propulsion and control if all blades but one were swept away. A bent blade does not destroy its proper function in propulsion but only decreases its effectiveness.

THE REBER PLAN

(Continued from Page 403)

damming the streams to prevent flood run off and feeding the water into the gravel beds gradually to raise the water level in the irrigation wells. The trend is toward smaller fresh water additions to the south bay basin, and larger summer flow of fresh water into the north bay basin; which, of course, would be equalized by the "fresh water canal" if the Reber Plan was installed.

Engineers who have investigated this plan and its ramifications report that there is not enough water running off from the Sacramento-San Joaquin Rivers to maintain the northern and southern lakes in a fresh water condition. Starting with a large part of the area above the barriers covered with salt water it is very doubtful if these lakes would ever be fresh. If they were fresh and subject to the same inflow of sewage, chemical waste, and garbage dumping as now exists these lakes could not safely be used as a source of water even for irrigation. The enforced cleaning up of this situation would tremendously add to the cost of the plan.

Many industries both on the northern and on the southern ends of the bay have located on their present sites because of free access to deep salt water. The total investment of these industries runs into billions of dollars. Some examples are: the U. S. Navy with yards at Hunters Point, Mare Island, Naval Base at Oakland; and other installations; the shipyards and terminals and many industries on the Oakland estuary and inner and outer harbors; all large San Francisco Bay shipyard and dry dock installations; all the sugar refineries; all the steel mills; and all the present port facilities of Oakland, Alameda, Berkeley, Richmond, Redwood City, San Mateo, San Jose, Stockton, Vallejo, Sacramento, Martinez, Crockett, and many other towns.

It is claimed that the creation of new reclaimed land by this plan would far more than pay for the cost. However, it can be shown that this plan destroys the value of present sites to a tremendous extent and perhaps to an extent much greater than the value of the new lands created. Much of this new land to be created by the Reber Plan would without this plan gradually be reclaimed under existing plans of port development projected by the various cities affected. These plans would make such land of greater value than would the Reber Plan because they preserve open access to deep salt water and maintain the values of present investments.

Much of the allure of living alongside a fresh water lake disappears when that lake is a shallow body of water resting on mud of great depth. That is something very different from the clean, clear, cold fresh water lakes of the mountain and forest regions. Shallow fresh water mud bottom lakes at sea level are very apt to become pest holes and magnificent breeding grounds for mosquitoes and other insects. Salt water is a much more healthful medium under such conditions.

From the maritime industry viewpoint this plan introduces much expense and many uncertainties. Locks are expensive to operate and cause expensive delays. This expense is always borne by the traffic that passes through the locks.

Every ship repair plant on the bay capable of hull repairs to large vessels is cut off from free access by this plan.

All the great canals in the world were built for the purpose of making navigation possible to some interior point, or for shortening the distance between points. The Reber Plan canal makes the navigable distance between the Golden Gate and points on the upper and lower bay longer and more congested and cuts off from the water approach a number of points that are now open to navigation. This canal passes under the San Francisco-Oakland bridge at a point where the clearance is rather low for large seagoing vessels.

Confining the tide to a limited portion of the bay will probably produce tidal surges that are dangerous to shipping at the docks.

The only advantages to shipping suggested by the proponents of the plan are (1) a constant level basin in which to load and discharge cargo (2) fresh water which (if the ship remains long enough) will clean the barnacles off her bottom. We doubt that advantage No. 1 would be sufficient to pay for the lockages, as for

MEASURED MILE

As the SS. Mount Whitney, Vancouver C-4 cargo ship, hit full speed in its measured mile test on the Columbia, a camera on the bank recorded this picture of its grace and symmetry. The Mount Whitney was delivered to the American-Hawaiian lines through the Maritime Commission and WSA February 21 for intercoastal service.

No. 2 we know that ships' hulls have to be dry-docked annually and are always fairly clean when in constant operation. If ships stayed long enough above the locks to drop all the barnacles the cost of delay would more than offset any reduction in fuel costs due to a clean bottom.

To the maritime interests therefore the installation of the Reber Plan means additional port costs, expensive delays, and in general a disagreeable nuisance.

We rather confidently expect and fervently hope that the Reber Plan will remain a plan. We like San Francisco Bay as it is.

ADMIRALTY DECISIONS

(Continued from Page 421)

thing, the result of the use of the lawyer's tongue, his pen, and his head for his client, and the court goes on to say that that sort of thing is pretty well described (although they do not adopt the phrase as a label for their concept) as the "work product" of the lawyer.

Of course it would be quite obvious to the layman that pictures of the winch in this case would be relevant, but it is quite conceivable that a lawyer, through his legal training and knowledge exercised in behalf of his client, might also obtain and direct the taking of photographs of other things which the average layman would not consider relevant and would not know were important in the case, and, yet, which might be the turning point of the whole case.

The court indicates a great deal of doubt as to whether the photographs come under the "privilege" as described in the opinion of the Circuit Court of Appeals but the court concludes that they come within the dictum of the Circuit Court of Appeals which deals with tangibles such as the piece of a machine which hurts someone. The court restricts its decision so that a future case might very well hold that photographs taken by a lawyer or under his direction and supervision may be cloaked by the guard of "privilege." The court finally concludes that the particular photographs are not entitled to the "privilege."

This decision puts considerable responsibility upon the shoulders of counsel in that some statements obtained from witnesses as well as photographs taken at the time of the injury, which may be in part beneficial and in part detrimental, might very well be called up for examination by adverse counsel prior to trial upon the order of the particular court in which the case is at issue.

Liberal Construction of Public Law 17

On Law and Motion day of various district courts of the United States, it is a common thing to hear arguments upon exceptions filed by counsel for various respondents in personal injury actions, where Public Law 17 has not been complied with in suits against the United States or there is a failure in the allegation in the libel respecting the compliance with that law.

In **McInnis** vs. **United States,** the Circuit Court of Appeals, 9th Circuit, a District Court Admiralty decree was appealed following the court's dismissal of the libel.

In that case, a seaman brought suit under the Suits in Admiralty Act, the libel alleging employment aboard the SS. Hobart Baker and personal injuries aboard the same vessel during the course of a voyage in the Pacific. The libel included two separate causes of action; namely (1) claim for injuries because of the insecurity of the gangway, and (2) claim for maintenance and cure.

In the absence of wartime legislation, the libel showed a right of recovery under 46 U.S.C., Sec. 742 and Sec. 741 of the Suits in Admiralty Act, since the Hobart Baker was operated as a merchant vessel by the United States. The question here is whether the seaman has been deprived of that right because of a claimed non-compliance with the provisions of 50 U.S.C., Sec. 1291, respecting his filing a claim for his injuries.

It was agreed that the libelant filed a claim with the agent of the War Shipping Administration and that it was disallowed. It was contended by the government that the claim did not sufficiently comply with the following section of the General Order No. 32 of the Administration:

> Section 304.24. Claim. Contents. The claim need not follow any particular form but it shall be in writing. It shall contain such particulars as are reasonably necessary as a basis for the allowance or administrative disallowance of such claim, and should include, with respect to the seaman in question, his home address, date of birth, place of birth, certicate of identification number, as well as all of the facts and circumstances leading up to and surrounding the happening of the event out of which it alleged the claim arose.

The first question is whether a claim filed and administratively disallowed because not fully satisfying Section 304.24 is a claim "administratively disallowed" within the provisions of 50 U.S.C., Sec. 1291.

The court was of the opinion that such a disallowance of such a claim permits the maintenance of this action. Such legislation concerning seamen's injuries and "maintenance and cure" has always been construed with extreme liberality in their favor. It was not contemplated that seamen in wartime voyages in foreign or domestic parts would have to leave the ship and seek and, if found, employ admiralty proctors to make out their claims for such injuries. The court does not believe that Congress intended that an inartificially drawn claim deprived a seaman of his right of recovery under the Suits in Admiralty Act.

The court specifically sets forth the allegations of the seaman's claim which, while not in complete form, certainly advised the War Shipping Administration and/or the world of the facts on which the claim is based. The court takes the view, of course, that the only reason for Public Law 17 was to give the United States prompt notice of existing claims against it and thereby afford the United States an opportunity to take any and all steps necessary to properly defend the claims. As it is conceded this was the object of the legislators in putting Public Law into force, we must assume that the court reached the proper decision in this case. In any event, it is certainly worth keeping in mind in order to avoid loss of considerable time.

The decree dismissing the libel was reversed.

Inasmuch as the court has taken this position in this district, it would appear to be useless to except to a libel where the only ground of the exception is that notice of claim is technically incomplete although it contains all of the facts surrounding the accident and injury.

The Probolog

There has been an urgent need for a long time for a reliable, non-destructive method of determining the internal and external condition of metal tubes in heat exchange equipment in the industrial and marine engineering fields, and at the same time providing a comparative record of the condition of each individual tube which would eliminate all guesswork and place exchanger maintenance on a logical, scientific basis.

The Shell Development's engineering department in cooperation with the refinery engineers of the Shell Oil and the Shell Chemical's instrument department are responsible for the development of a handy, compact piece of electronic equipment known as the Probolog which when inserted and drawn through condenser tubes of non-magnetic metals, will detect and record quantitatively all types of irregularities such as pinholes, cracks, corrosion and erosion pits, differences in wall thicknesses, and differences in chemical composition. Since it inspects the tubes from the inside, it requires no preparation of the equipment before inspection other than the removal of the exchanger head. It may be operated either as an indicator or recorder, and the record is of such a nature that it can be conveniently retained for direct comparison with those of other tubes or with those of other inspections of the same tube at different lengths of service.

The Instrument

The Probolog consists of the following parts:

One or more interchangeable probes of diameters to fit standard sizes of tubing.

A mechanical probe puller usually synchronized with the chart drive of the recorder so as to insure a reproducible record.

An electronic recorder, equipped with a continuous strip-chart, but also incorporating a neon blinker which may be used as an indicator when a record is not required.

The Probolog may be employed in several ways depending on the particular application and the data sought. For inspection of tube bundles during a routine power plant shutdown the following two-step procedure is favored somewhat:

(a) using the instrument first as a visual indicator, with the chart drive and probe puller cut out, a rapid preliminary survey is made of all the tubes. The neon light is set to flash whenever a signal exceeding a specified minimum intensity is transmitted by the probe and the operator explores the tubes as rapidly as he can draw the probe through. Those tubes which are shown by flashes of light to contain a defective area are marked for further inspection, and the remainder passed as satisfactory.

(b) a second inspection of the marked tubes is then made using the strip-chart recorder and the probe puller synchronized so as to draw the probe through the tube at a standard rate, say ten feet per minute. A permanent record is thus obtained of the internal condition of each suspected tube, in which each defect is not only shown graphically but is located along the tube. The record of a faulty tube consists of a series of deflections from a central line (at which the pen is originally set by testing a tube known to be in good condition) and the magnitude of each deflection is proportional to the extent of the particular defect. Relatively little experience is required for proper interpretation of these records, and an objective basis is thus provided for the retention or rejection of each partially corroded tube.

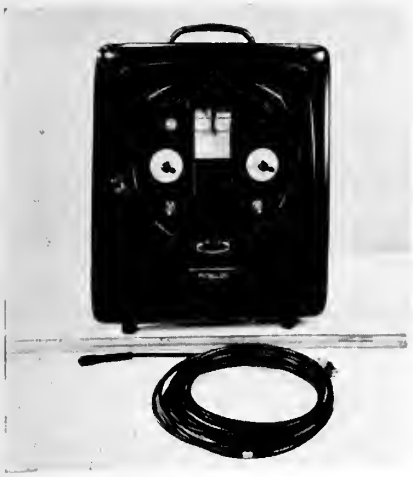
Electronic recorder, ½" probe with long flexible cable and sample tube with perforations used for demonstration. Record of tube detect is shown on strip chart. Bulb to left of chart is Neon blinker used in rapid qualitative inspection technique.

Limitations

The present instrument is designed specifically for the inspection of non-magnetic tubes including copper, brass, monel, Admiralty metal, copper-nickel, aluminum, magnesium, and austenitic stainless steels. For basic reasons, it is unsuitable for the examination of steel tubes although a modified instrument adapted to magnetic metals is at present under development.

The standard commercial model requires 110-volt, single phase, 60-cycle alternating current as a power source although it may be adapted to any special situation. No other outside connection is necessary.

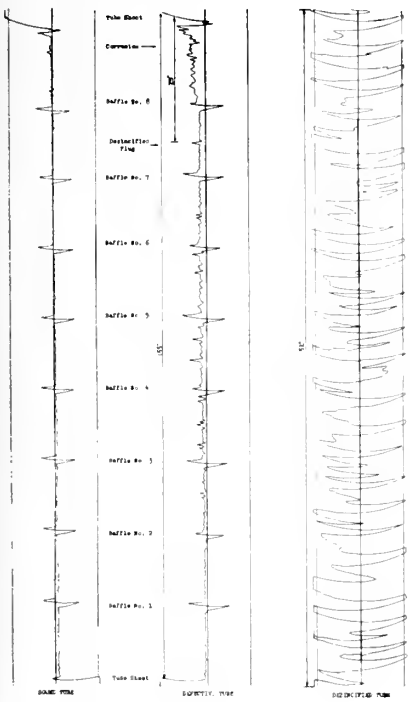
Metallic baffles and tube sheets appear on the record as defects, causing a wide swing of the pen. Since these deflections are of a large order



The Shell Probalog is seen here in action at a plant. Readers will readily identify the mechanical puller, the insulated wire to which the probe is attached, and the electronic recorder.

of magnitude, however, and occur at regular intervals, proper allowance may be made and the record is not obscured. When records of several tubes are made consecutively on a continuous strip of recorder paper the wide deflections caused by the terminal tube sheet actually serve to separate the logs of individual tubes. Scale and other non-metallic deposits are without effect on the record, so that the bundle need only be cleaned to the extent necessary to allow passage of the probe.

These records made by the Shell Probalog shaw how the electronic device reveals damage. Note the regular line drawn when a tube is sound.



The Marine Demonstration

The justification for an instrument of this kind has been fully demonstrated for some considerable time in oil refinery plants where it has repaid its cost many times over in terms of savings in heat exchanger tubes saved from the scrap heap. In order to introduce the Probolog to the marine engineering fraternity the Shell Development Company staff recently gave a demonstration of its use in the marine field. This demonstration took place in the engine room of the ship Trinity Victory in the San Francisco yard of the Bethlehem Steel Company on April 12, where the tubes of the main condenser were thoroughly investigated by the use of the Probolog. Those attending the demonstration included several members of the shipbuilding company's engineering staff, a number of U. S. Navy Yard officials in the Bay Area, and some local shipping companies' port engineering staff members. All present seemed deeply interested and considerably impressed by the demonstration and the findings resulting from the use of the Probolog.

The Shell Development Company, Inc., at 50 West 50th Street, New York City, will be pleased to supply any information on the Probolog upon request.

Chart Program of Hydrographic Office

(Continued from Page 430)

"curves" or hyperbolic lines of position printed on them.

Between April 1943, and November 1945, two and one-half million of these charts were made. In one month, May 1945, over 350,000 were printed. These loran charts and tables are among the special charts produced during the war which will continue to be of increasing importance in the future to both mariner and aviator.

The North Atlantic, the Atlantic Coast of North America, the Aleutians, and the main routes across the Pacific are now well-served by loran stations. The Pacific Coast of North America will soon have complete coverage.

Nautical Charts

The construction of regular Hydrographic Office nautical charts continued as usual, despite the many other special charts that were called for. In fact, with many more ships of all kinds on the seas, the demand for regular nautical charts increased. These include general charts and harbor charts showing soundings, shorelines, landmarks, aids to navigation, and other information of value to navigators.

The famed Pilot charts of the Navy were the basis for the rubber raft and the waterproof "handkerchief" charts for aircraft, developed during the War. They show ocean currents, winds, and surface temperatures for each month, the factors in which navigators at sea are most interested. The waterproof charts stowed in the handles of paddles on life rafts were used for various other emergency purposes such as collecting rainwater, as a protection against weather or exposure to the sun, and as a sail or distress signal. Using a surface pilot chart base, the upper air pilot charts show atmospheric conditions over the oceans at four different levels. The United States Weather Bureau supplies the information on which these charts are constructed. These charts will increase in importance not only to the Navy, but to private enterprise as transoceanic air becomes more common.

Other nautical charts include magnetic variation charts, which show compass variation for all parts of the world, and gnomonic charts, useful for obtaining great-circle courses and distances. Polar projections are published for use in higher latitudes.

The wartime problem of keeping naval and merchant ships informed of rapidly changing conditions has been enormous. Now, the Hydrographic Office is in the midst of the task of again revising these nautical charts as areas are swept of mines, harbors rebuilt, dangers removed, and navigational aids restored. Most merchant ships will have to be supplied with complete new sets of charts.

(To be continued)

During the war the San Francisco distribution depot dwarfed its parent office in activity, issuing as many as 30,000 charts a day to Navy and merchant ships.

Navy ships drew 1,173,840 charts and 19,549 publications during the war. Maritime ships, during the same period, drew 1,130,853 charts and 84,508 publications.

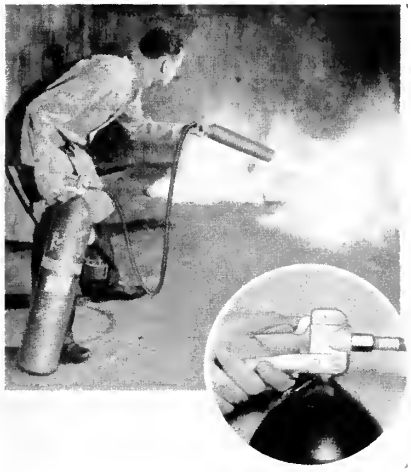
NEW EQUIPMENT AND MACHINERY FOR YARD, SHIP AND DOCK

Trigger-Touch Fire Extinguisher

Randolph Laboratories, Chicago, have produced a new trigger-touch 15 lb. CO_2 fire extinguisher that is carried and operated with uninterrupted, single-sweep action. Grasping the unit by its arched-steel handle, the operator removes the extinguisher from its bracket, carries it with one hand only while the other is free to remove obstacles and open doors en route to the scene of action.



During fire fighting, the operator can grasp the nozzle handle with his free arm and aim it at the base of the flames. One touch of the thumb-trigger discharges a penetrating, snowy blanket of carbon dioxide gas, smothering an eight quart gasoline fire in nine seconds under official Underwriters' Laboratories fire test. The release of the trigger automatically stops the flow which saves the remainder of the charge for another occasion.

Truck and wall bracket models are provided for both vehicle and factory installations. The long-range hose and nozzle keeps the fire-fighter at a safe distance from the heat of the blaze, permitting easy access to overhead, side-wall or engine compartment fires.

Turco Hydro Steam Cleaning Unit

The Turco hydro steam unit, manufactured by Turco Products of Los Angeles, is a unit which utilizes your own steam supply and gives you the same powerful cleaning action as produced by steam cleaning plants costing a lot more.

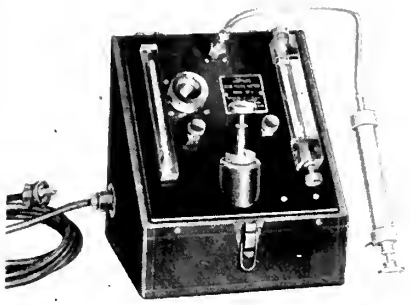
The hydro steam unit is portable and weighs only 28 pounds, with quick couplings that permit fast connection. Any steam line maintaining 80 to 150 lbs. pressure with a ¾-inch valve outlet is all that is required for connecting the unit. The manufacturers claim that this unit is safe, easy to operate and has no moving parts, pumps, pressure tanks, motors, electrical connections, toxic or explosive cleaning agents to cause danger.

Three manual controls vary the temperature, quantity of solution and nozzle pressure to handle the needs of the job at hand. A wide variety of Turco specialized compounds can be used through this unit to clean anything from delicate aluminum surfaces to heavy construction equipment caked with grease and dirt.

Alnor Precision Dew Point Indicator

The Alnor Dew Point indicator, Model 8, is an improved instrument for simple rapid determination of dew point, relative humidity, grains moisture per lb., and latent heat of any non-corrosive gas. It has many uses in air conditioning and refrigeration work; in connection with controlled atmospheres in furnaces; in the chemical industry; in the petroleum industry, paper making, and the production of compressed gases.

Its operation is simple and easy, and an outstanding advantage of the indicator is the fact that the indication takes place in an enclosed observation chamber under conditions



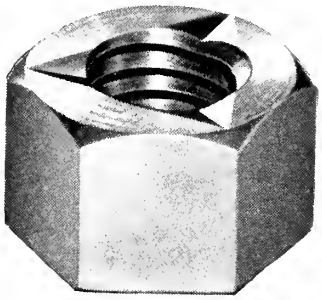
which can be controlled and reproduced. Condensation takes place suspended in the air or gas sample and the end point or vanishing point may be accurately observed, reducing errors due to the human element, and permitting consistent determinations by two or more observers. This instrument does not require an external coolant.

The instrument is a complete unit, readily portable and not requiring external cooling means or auxiliary apparatus. This Model 8 can measure the dew point of high pressure gases through a pressure reducing valve.

Note that the Model 8 Alnor indicator is accurate below 32 deg. F. as well as above, that determinations take at the most a few minutes, and that observation of fog and vanishing point is plain and accurate, without variables found in observing condensation on a mirror.

New Low Cost Lock Nut

The Grip Nut Company of Chicago is now offering a new lock nut for general industrial use called the Gripco Lock Nut. The nut is a semi-finished, one piece, self-locking unit of standard dimensions, and is not affected by oil, water or chemicals. It requires no lock washers or cotter pins, and a wrench is all that is needed to apply or remove it. The patented, triangular deflections on the top of the nut provide a controlled friction lock. The nut is free-spinning until the bolt threads contact the deflected threads near the top of the nut.

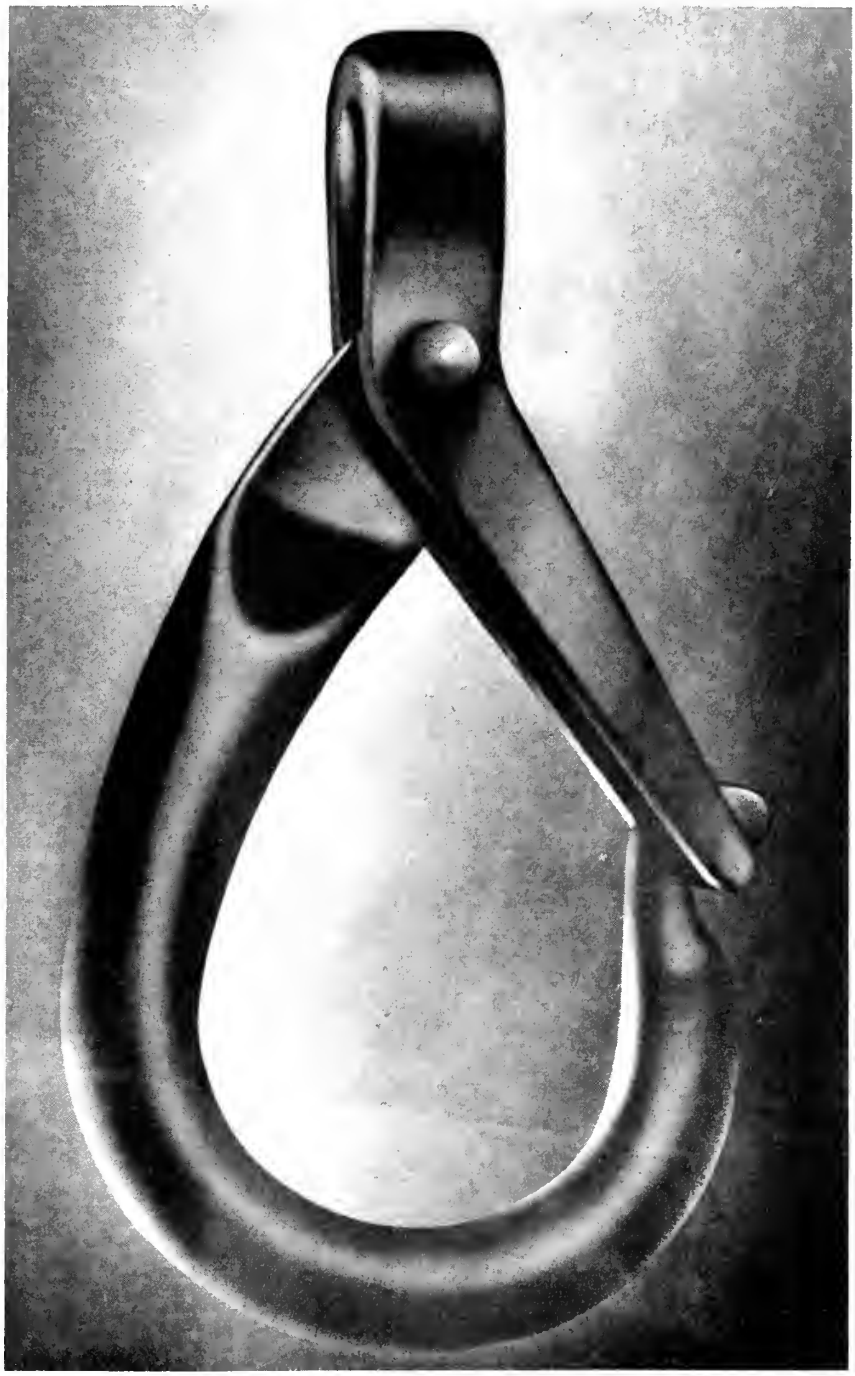


ACLC Safety Hoist Hook

American Chain Ladder Company safety hoist hook is not merely built but engineered for utmost safety. The dangers which often threaten life, limb and load do not happen when ACLC safety hoist hooks are used.

Makeshift mousing gives place to automatic mousing. It is an ancient practice to "mouse" a hook by passing several parts of rope around the hook. This "mousing" provides a measure of support to the hook and a precaution against the sling jumping the hook. At its best, however, this device is unsatisfactory due to various causes, such as stretch of the rope. Its application consumes time and it is entirely impracticable for regular handling of loads, such as loading and discharging cargoes.

Snagging can not occur because there is no protruding point in the way. Hook straightening and load slippage are avoided because the pat-



ented shoulders and lip lock the load in perfect alignment.

The ACLC safety hook automatically engages and disengages as the load is applied and released. Entirely automatic and simple in operation, it provides just as rapid handling and a higher degree of safety than the common cargo hook.

"Insalize" Now Available

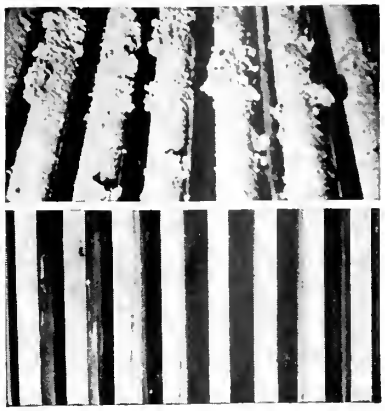
Long deyayed by war-time shortages of essential ingredients, the Lumanize Products Company, Chicago, announces that their universal liquid insulator, "Insalize," is now available. Its high dielectric strength and great resistance to moisture, heat, acids, alkalis and oils, have the effect when applied to bare or insulated ignition and electrical systems, of eliminating corrosion and of preventing current leakage.

"Insalize" has the property of

eliminating corrosion on electrical connections and at battery and starter terminals; of correcting open shorts in armatures and fields of electric motors; of insulating coils, distributors, spark plugs, armatures and wiring; of reducing radio interference; and of assuring waterproof and leakproof insulation against water, condensation and fog which normally account for much starter trouble and faulty motor performance.

Chemical Compound Minimizes Manual Cleaning

The Gamlen Chemical Company, of Pittsburgh and San Francisco, offers a product named Gamlenite, which removes hard slag and other combustion deposit from tubes and other boiler metal surfaces, and from furnace refractory walls, by chemical means. Gamlenite is a powder which



Upper view shows typical hard combustion deposit on boiler tube section. Lower view illustrates boiler tube section after application of gamlenite.

is blown into the furnace while it is in regular operation. It forms a dense non-poisonous vapor which reaches all parts of the furnace and firesides of the boiler metal. Its use minimizes the necessity for taking the boiler off the line to do the cleaning job manually.

Gamlenite exerts a reducing action, breaking down hard combustion deposit into a soft powder which is carried up the stack by the draft. It also Gamlenizes the boiler metal, which provides maximum resistance against corrosion, and greatly retards re-accumulation of further combustion deposit.

DEHUMIDIFICATION

(Continued from Page 411)

moisture and corrective measures taken. This instrument will contribute much toward reducing the cost of maintaining the Inactive Fleet in future years.

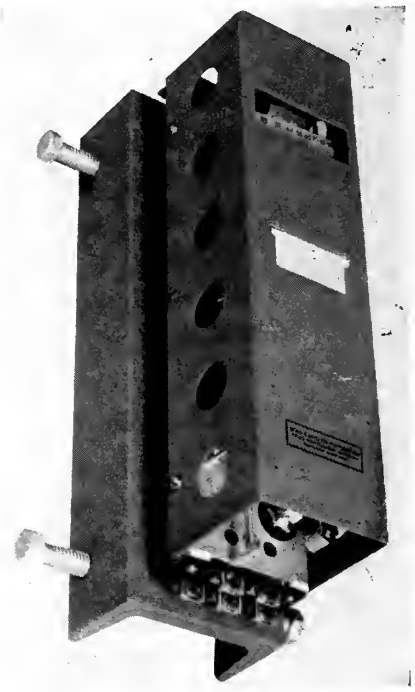
In conclusion, it can be said that Dehumidification, as carried out by the above procedure, is an economical means of preserving a costly investment in valuable ships. The installed equipment cost is less than one cent per cubic foot of ship's volume in the majority of cases. The power cost will run well below 15 cents per 100,000 cubic feet of volume per day with power at one cent per kw hour. The attendant Dehumidification power cost for a Destroyer having a volume of approximately 250,000 cubic feet will be about $110 per year on a $7,000,000 investment. A 35,000-ton battleship, costing from 90 to 100 million dollars, would have an attendant Dehumidification power cost of $1,550. Therefore, it is obvious from these examples that the economy of dehumidification as a preservation measure is attractive to the taxpayer. In addition, preservation with dry air will provide an excellent means of preserving American sea power in a state of readiness for any and all emergencies.

The Bendix Central Station records the temperature, humidity and time as well as the code number of the particular Measuring Unit at which the measurement was made. In addition, it starts or stops the dehumidification apparatus. This control is based on the average of the readings from the individual Measuring Units, automatically computed by the Central Station.

The relative humidity is printed within a range of 10% to 90% plus-minue 5%, and the temperature from 0 to 120° F. plus-minus 3½°. When these records have been printed for the first Measuring Station, the seven other stations report, one after the other, so that a complete record of all eight stations is available every fifteen minutes. Also, records may be printed continuously, once each 12 hours, or at those times when they are desired.

As each Measuring Unit reports the local humidity condition to the Central Station, the readings are added and, after the eighth station has reported, this total is averaged. If this average is obove a selected value, such as 30% R.H., the electrical circuit to the dehumidification mochinery is energized. If below, no action is required. This "control by average" instead of by individual station is an economy factor and is a fully automatic function.

The Recorder-Controller operates on a voltage of 100 to 125 volts, 60 cycles, A.C., and includes a transformer for use on a 440-volt input. The average power requirements do not exceed 200 volt-amperes. Manufactured by the Friez Instrument Division of Bendix Aviation Corporation, Baltimore 4, Maryland.

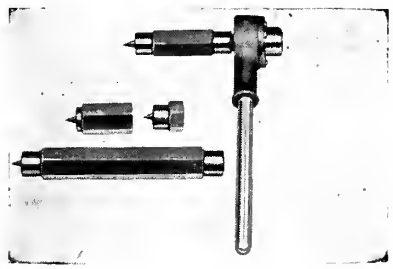


"Liberty" Ratchet Drill-Driver

Development of the new "Liberty" ratchet drill-driver is announced by Techtmann Industries, Milwaukee, Wisconsin, national distributors, manufactured by the Liberty Tool & Machine Co.

Designed for drilling between studs and joints or restricted spaces in buildings or other structures, this tool gives positive feed at each turn of the drill bit. The compact head allows centering of holes within 1¼ inches of the nearest obstruction. Any standard wood bit can be used. Steel drills can be used with an adapter chuck.

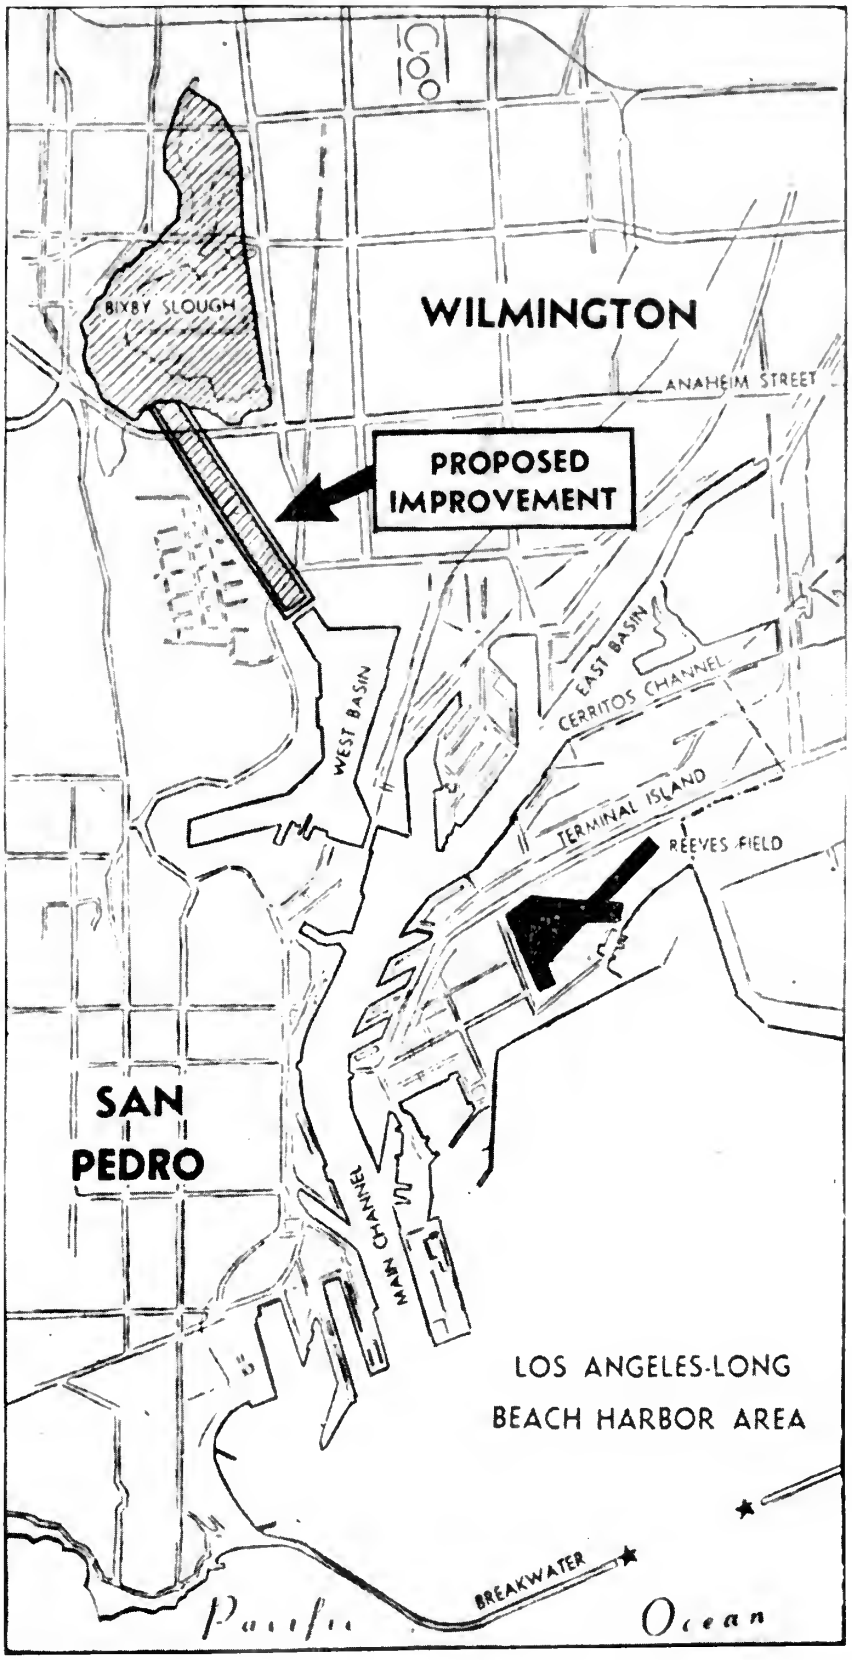
The thrust of the lead screw is carried directly to the drill shank by a solid shaft. Large wearing surfaces hardened to a depth of .010 inch insure long service under severe conditions. If necessary, any part can be readily replaced. The



ratchet is fully enclosed in a strong, semi-steel head, providing protection against dirt. A long lead screw in combination with 1", 2" and 8" extensions allows use of the ratchet drill-driver over a wide range of dimensions. In actual use, holes up to 3" diameter have been drilled without difficulty.

Although intended primarily for use on wood members, steel plates or beams can also be drilled by reducing the feed, which can be done by revolving the lead nut in the same direction as the drill.

Proposed Extension of Los Angeles Harbor Uptown



Upper left shaded section of adjoining map shows facilities that would be added to Los Angeles Harbor if Army Engineers who are now studying the plan finally go ahead. Bixby Slough is at present below sea level, separated from the harbor by higher land through which the suggested canal would cut. A hearing will be held by the Army Engineers soon.

KINMONT OCEAN-GOING HYDRAULIC DREDGE

(Continued from page 399)

plant. It consists of four individual Diesel generator sets, with total horsepower of 3750, composed of two sets of 1500 hp each, one set of 500 hp and a small set of 250 hp. These four sizes of Diesel generator sets shall be considered only as an example, as any other arrangement of different horsepower can be selected depending on requirements. In the example it is easy to note that various combinations of horsepower can be obtained by cutting out one or two of the generating sets. The small 250 hp is sufficient to take care of all needs during shut-down time, including the use of hoisting units. In case the dredge is equipped with "Kinmont Propelling Device" for self-propulsion at sea, the power plant described above takes care of this arrangement to perfection. The electric current characteristics and electric control equipment will not be discussed here. Each case shall be treated individually. The same applies to bunker capacity, fresh water system, sanitary system, lighting system and all auxiliaries.
